

Long-term oncologic outcomes of laparoscopic nephroureterectomy versus open nephroureterectomy for upper tract urothelial carcinoma: a systematic review and meta-analysis

Su Zhang, You Luo, Cheng Wang, Sheng-Jun Fu, Li Yang

Background Several factors have been validated as predictors of disease recurrence in upper tract urothelial carcinoma. However, the oncological outcomes between different surgical approaches (open nephroureterectomy versus laparoscopic nephroureterectomy, ONU vs LNU) remain controversial. Therefore, we performed a meta-analysis to evaluate the oncological outcomes associated with different surgical approaches. **Methods** We conducted an electronic search of the PubMed, Embase, ISI Web of Knowledge and Cochrane Library electronic databases through November 2015, screened the retrieved references, collected and evaluated the relevant information. We extracted and synthesized the corresponding hazard ratios (HRs) and 95% confidence intervals (95% CI) using Stata 13. **Results** Twenty-one observational studies were eligible for inclusion in the meta-analysis. The results of the meta-analysis showed no differences in the intravesical recurrence-free survival (IRFS), unspecified recurrence-free survival (UnRFS) and overall survival (OS) between LNU and ONU. However, improvements in the extravesical recurrence free survival (ExRFS) and cancer specific survival (CSS) were observed in LNU. The pooled hazard ratios were 1.05 (95% CI: 0.92-1.18) for IRFS, 0.80 (95% CI: 0.64-0.96) for ExRFS, 1.10 (95% CI: 0.93-1.28) for UnRFS, 0.91 (95% CI: 0.66-1.17) for OS and 0.79 (95% CI: 0.68-0.91) for CSS. **Conclusion** Based on current evidence, LNU could provide equivalent prognostic effects for upper tract urothelial carcinoma, and had better oncological control of ExRFS and CSS compared to ONU. However, considering all eligible studies with the intrinsic bias of retrospective study design, the results should be interpreted with cautions. Prospective randomized trials are needed to verify these results.

Long-term oncologic outcomes of laparoscopic nephroureterectomy versus open nephroureterectomy for upper tract urothelial carcinoma: a systematic review and meta-analysis

25 **Abstract**

26 **Background**

27 Several factors have been validated as predictors of disease recurrence in upper tract urothelial
 28 carcinoma. However, the oncological outcomes between different surgical approaches (open
 29 nephroureterectomy versus laparoscopic nephroureterectomy, ONU vs LNU) remain
 30 controversial. Therefore, we performed a meta-analysis to evaluate the oncological outcomes
 31 associated with different surgical approaches.

32 **Methods**

33 We conducted an electronic search of the PubMed, Embase, ISI Web of Knowledge and
 34 Cochrane Library electronic databases through November 2015, screened the retrieved
 35 references, collected and evaluated the relevant information. We extracted and synthesized the
 36 corresponding hazard ratios (HRs) and 95% confidence intervals (95% CI) using Stata 13.

37 **Results**

38 Twenty-one observational studies were eligible for inclusion in the meta-analysis. The results of
 39 the meta-analysis showed no differences in the intravesical recurrence-free survival (IRFS),
 40 unspecified recurrence-free survival (UnRFS) and overall survival (OS) between LNU and ONU.
 41 However, improvements in the extravesical recurrence free survival (ExRFS) and cancer specific
 42 survival (CSS) were observed in LNU. The pooled hazard ratios were 1.05 (95% CI: 0.92-1.18)
 43 for IRFS, 0.80 (95% CI: 0.64-0.96) for ExRFS, 1.10 (95% CI: 0.93-1.28) for UnRFS, 0.91 (95%

CI: 0.66-1.17) for OS and 0.79 (95% CI: 0.68-0.91) for CSS.

Conclusion

Based on current evidence, LNU could provide equivalent prognostic effects for upper tract urothelial carcinoma, and had better oncological control of ExRFS and CSS compared to ONU. However, considering all eligible studies with the intrinsic bias of retrospective study design, the results should be interpreted with cautions. Prospective randomized trials are needed to verify these results.

Introduction

Upper tract urothelial carcinoma (UTUC), accounting for only 5% of all urothelial cancers, is a rare malignancy with high risk for disease recurrence and mortality.(Roupret et al. 2015) Given its high potential for recurrence and poor prognosis, assessment of the predictive factors appears to be increasingly significant. Tumor multifocality, previous bladder cancer and concomitant carcinoma in situ (CIS) have been validated as predictors of intravesical recurrence, which is also associated with different surgical approaches.(Xylinas et al. 2013; Xylinas et al. 2014) The standard treatment for UTUC is nephroureterectomy with bladder cuff excision. The treatment approaches include open nephroureterectomy (ONU) and laparoscopic nephroureterectomy (LNU). Compared with ONU, a traditional approach which has durable oncologic control, LNU has shown several advantages with fewer adverse intra- and perioperative outcomes as a minimally invasive treatment since being first introduced by Clayman in 1991.(Clayman et al. 1991; Simone et al. 2009) However, compared to ONU, whether LNU has equivalent oncological outcomes, such as cancer-specific survival (CSS) and intravesical recurrence-free survival (IRFS), remains controversial.(Kim et al. 2015; Xylinas et al. 2014) We aimed to perform a meta-analysis to evaluate the oncological control associated with different surgical approaches (ONU vs LNU).

Methods

Search and screen strategy

A systematic literature search of Embase, PubMed, ISI Web of Knowledge and Cochrane Library was conducted to retrieve UTUC studies comprising both surgical approaches (ONU and LNU) through November 1, 2015. The search key words included *open nephroureterectomy*, *laparoscopic nephroureterectomy*, *upper tract urothelial carcinoma*, and others. The detailed search strategy is presented in supplement 1. We also screened the citations in the retrieved articles for any relevant studies. Two independent investigators (S Zhang and Y Luo) conducted the initial screening by reviewing the title and abstract. Then, the full-text articles satisfying the inclusion criteria were reviewed. Clinical studies recording any evaluation of the surgical approach on oncological outcomes, including intravesical recurrence-free survival (IRFS), extravesical recurrence-free survival (ExRFS), unspecified recurrence-free survival (UnRFS, reported as disease recurrence but not explicitly defined as IRFS or ExRFS), cancer-specific survival (CSS) or overall survival (OS), were eligible. Articles were excluded if they met any of the following criteria: 1) the aforementioned outcomes were not described; 2) patients were treated by hand assisted laparoscopic nephroureterectomy; or 3) studies included overlapping patients or duplicated data. Instead, the study with the largest sample size would be selected if more than one study included overlapping patients. This systematic review was performed according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses statement (PRISMA)(Moher et al. 2010). Ethical approval and patient consent were waived because all available data were extracted from previous publications.

Data extraction and assessment of methodological quality

The basic information including first author, year of publication, region, recruitment period, number of patients who underwent LNU or ONU, age of patients, follow-up, oncological outcomes, and adjusted factors were extracted by two researchers (S Zhang and Y Luo) independently. Any disagreement or uncertainty was determined by group discussion, and a consensus was obtained. The data were extracted from the original articles. For incomplete data, we attempted to contact the corresponding author to acquire primary data. During data extraction, multivariate outcomes rather than univariate outcomes were preferred when both results were provided. If multivariate results were not available, univariate outcomes were an alternative to conduct this analysis. Publication bias and sensitivity analyses were applied. The quality assessments of cohort studies were conducted according to the Newcastle-Ottawa Scale (NOS), which was developed to assess bias risk including three domains with eight items. Five or more stars out of a total of nine stars was regarded as good quality.(Wells GA 2008)

Statistical analysis

All data and analysis were conducted using STATA 13 software (Stata Corp LP, College Station, TX, USA). The survival outcomes were evaluated by hazard ratios (HR) and 95% confident intervals. I^2 statistics and the chi-square test were calculated for heterogeneity detection. When $P \geq 0.1$ and $I^2 \leq 50\%$, a fixed-effects model was performed; otherwise, a random effects model was applied. An inverse variance method was used to calculate the pooled hazard ratio. Sensitivity analyses were conducted to test the stability of the pooled results. Egger's test for publication bias was performed only in outcomes that enrolled more than ten studies.(Egger et al. 1997) Additionally, we conducted subgroup and multivariable meta-regression in IRFS

according to the different approach of LNU (retroperitoneal vs transperitoneal), sample size of LNU (< 100 vs ≥ 100) and publication year. A P value of less than 0.05 was deemed statistically significant.

Results

Description of included studies

In total, 1506 citations were retrieved by the initial search strategy. After three rounds of screening, there were 21 cohort studies for quantitative synthesis. The PRISMA flow diagram is presented in Figure. 1. Table 1 shows the detailed characteristics of the included studies. The Newcastle Ottawa Scale (NOS) assessment showed that all included cohort studies had relatively well controlled quality.

Survival outcomes

1. Oncological Recurrence

The IRFS was reported in thirteen articles, which included LNU (n=1959) and ONU (n=4281).(Favaretto et al. 2010; Fradet et al. 2014; Ishikawa et al. 2010; Ito et al. 2013; Kim et al. 2015; Kitamura et al. 2014; Kobayashi et al. 2012; Koda et al. 2007; Kume et al. 2006; Ploussard et al. 2015; Terakawa et al. 2008; Xylinas et al. 2013; Zou et al. 2014) The meta-analysis results showed no significant difference in the IRFS between LNU and ONU management (HR 1.05, 95% CI: 0.92-1.18; $P = 0.134$, $I^2 = 31.1\%$; Fig. 2). The ExRFS was described in four studies including patients who underwent LNU (n=836) and ONU (n=4315).(Capitanio et al. 2009; Rieken et al.

2014; Walton et al. 2011; Yafi et al. 2012) The pooled results showed that LNU management decreased the risk of extravesical recurrence (HR 0.80, 95% CI: 0.64-0.96; $P = 0.859$, $I^2 = 0.0\%$; Fig. 3). Five studies including LNU (n=1126) and ONU (n=1403)(Ariane et al. 2012; Fairey et al. 2013; Favaretto et al. 2010; Metcalfe et al. 2012; Terakawa et al. 2008) reported the UnRFS. The pooled analysis of the available HRs showed that the different surgical procedures were not significantly correlated with disease recurrence (HR 1.10, 95% CI: 0.93-1.28; $P = 0.337$, $I^2 = 12.0\%$; Fig. 4).

2. Mortality

Among the four studies that provided the HRs of OS, there were 1442 LNU patients and 3119 ONU patients.(Fairey et al. 2013; Kim et al. 2015; Metcalfe et al. 2012; Rieken et al. 2014) There was significant heterogeneity ($P = 0.091$, $I^2 = 53.7\%$; Fig. 5), and a random model was applied. The model showed that neither LNU nor ONU significantly increased the risk in the overall survival (HR 0.91, 95% CI: 0.66-1.17; Fig. 5). The CSS was described in ten articles, in which 2518 patients were treated by LNU and 8342 patients were treated by ONU.(Ariane et al. 2012; Capitanio et al. 2009; Fairey et al. 2013; Ishikawa et al. 2010; Kim et al. 2015; Ploussard et al. 2015; Rieken et al. 2014; Walton et al. 2011; Yafi et al. 2012; Zou et al. 2014) The pooled results indicated that LNU could improve the cancer specific survival (HR 0.79, 95% CI: 0.68-0.91; $P = 0.186$, $I^2 = 28.1\%$; Fig. 6).

3. Subgroup analysis and multivariable meta-regression for IRFS

In subgroup analysis for the effect of different approaches of LNU on IRFS, no difference were seen among people with retroperitoneal laparoscopy (HR 1.04, 95% CI: 0.77-1.32; $P = 0.598$, I^2

170 = 0.0%; Fig. 7) and transperitoneal laparoscopy (HR 0.81, 95% CI: 0.48-1.13; $P = 0.548$, $I^2 =$
 171 0.0%; Fig. 7). The subgroup of five studies with sample sizes of LNU more than 100 had a
 172 combined HR of 1.31 (95% CI, 0.92-1.70) with significant heterogeneity ($P = 0.011$, $I^2 = 69.5\%$;
 173 Fig. 8), while the subgroup of eight studies with sample sizes of less than 100 had a combined
 174 HR of 0.97 (95% CI: 0.67-1.16) without significant heterogeneity ($P = 0.919$, $I^2 = 0.0\%$; Fig. 8).
 175 Multivariable meta-regression showed no particular influence of different approaches of LNU (P
 176 = 0.431), sample size ($P = 0.899$) and publication year ($P = 0.729$) on the results.

177

178 Publication bias and sensitivity analysis

179 The publication bias detection was conducted by Egger's asymmetric test and only for IRFS
 180 outcomes. The P value of the linear regression was 0.515, and no significant publication bias was
 181 observed (Fig. S1). We also performed sensitivity analyses of IRFS and CSS, and no significance
 182 change was observed (Fig. S2 and Fig. S3).

183

184 Discussion

185 Recently, some retrospective studies have paid attention to the predictors of disease recurrence in
 186 patients with UTUC after RNU; these studies found that CIS, previous bladder cancer,
 187 laparoscopic surgery and distal ureteral management were risk factors for disease
 188 recurrence.(Xylinas et al. 2014) A systemic review concluded that a laparoscopic approach
 189 significantly increased the risk of intravesical recurrence.(Seisen et al. 2015) However, there are
 190 many studies that suggested that laparoscopic surgery could provide equivalent oncologic control

compared with open surgery.(Favaretto et al. 2010; Ishikawa et al. 2010) Therefore, we conducted this meta-analysis enrolling twenty-one retrospective studies that contained various oncologic outcomes to assess whether LNU would show a tendency toward a poor prognosis for UTUC patients.

Open nephroureterectomy, the traditional surgical approach that could support a durable tumor control, has long been accepted as the standard surgical treatment for UTUC, especially for high-risk UTUC(Roupret et al. 2015). As a viable minimally invasive therapy, LNU was developed in an effort to reduce the morbidity of the surgical management and had advantages of lesser blood loss, shorter hospital stay and oncologic outcomes compared with ONU. With a median follow-up of 45 months of 1261 UTUC patients who underwent ONU (n = 926) or LNU (n = 335), Xylinas *et al* showed that the laparoscopic approach was associated with a higher risk of intravesical recurrence compared with open surgery (HR=1.5, 95% CI, 1.17-1.93).(Xylinas et al. 2014) It was suggested that the high pressure pneumoperitoneum during LNU might trigger tumor dissemination and could result in a higher rate of recurrence, which contributed to the debate on oncologic outcomes of UTUC patients after laparoscopic procedures. Few cases of laparoscopic port-side seeding were reported in some literature in the early years, and Rouprêt *et al* proposed that ensuring a closed system during laparoscopic surgery and avoiding direct contact between instruments and tumors might favor tumor control.(Roupret et al. 2015) In 150 laparoscopic surgeries, Ariane *et al* reported three cases of laparoscopic port-side seeding occurred in early experiences. After the widespread use of laparoscopic bags for specimen extraction, no cases happened.(Ariane et al. 2012) Our pooled results demonstrated that LNU

could provide equivalent tumor control of intravesical recurrence and unspecified RFS compared to ONU. However, the majority of the enrolled studies reported negative control for ONU in extravesical recurrence. Our results showed that ONU was an independent risk for ExRFS. However, considering that there were only four articles enrolled, whether open surgery increased the risk of extravesical recurrence still needs further exploration. Our analysis based on the current evidence did not support the view that laparoscopic surgery increased the risk of disease recurrence of patients with UTUC after nephroureterectomy.

Regarding survival outcomes, our data demonstrated that LNU was comparable to ONU in overall survival, and superior in cancer specific survival. In the first randomized prospective study, the cancer specific survival rate and the metastasis free survival rate were significantly different between the LNU and ONU groups, which favored ONU after matching for pT3 and high-grade tumors.(Simone et al. 2009) In the 2015 EAU guidelines, invasive or large (T3/T4 and/or N+/M+) tumors were deemed as contraindications for a laparoscopic approach.(Roupret et al. 2015) Recently, Kim *et al* retrospectively analyzed the data of 371 UTUC patients who underwent ONU (n = 271) or LNU (n = 100); the results indicated that LNU had worse five-year OS and CSS rates than the ONU group only in locally advanced disease (pT3/T4) after stratifying by pathological stages.(Kim et al. 2015) However, this conclusion was not identified in Arian's research in tumors of the pathological stages of pT3/T4.(Ariane et al. 2012) A recent study including 749 muscle-invasive UTUC patients who underwent ONU (n = 527) or LNU (n = 222) also indicated that the oncological outcomes of LNU were not inferior to the outcomes of ONU.(Miyazaki et al. 2015) Although our analysis did not include a subgroup analysis of

survival outcomes (OS and CSS) in locally advanced UTUC patients because of a lack more relevant survival data, our results might be reliable because the majority of our data were extracted from multivariate analyses, the majority of which adjusted for the effect of tumor stages and grades. Furthermore, a previous systematic review also showed that no significant differences in the stages of pT3/T4 or pathologic grades were observed in the LNU group compared with the ONU group.(Ni et al. 2012)

Previous systematic reviews on the oncologic outcomes comparing LNU with ONU were published in 2012.(Ni et al. 2012; Rai et al. 2012) These cumulative analyses conducted by using non-time to event data suggested that LNU could offer reliable perioperative safety and comparable oncologic efficacy compared to ONU. The meta-analysis conducted by Ni *et al* indicated that LNU could improve the 5-yr CSS and decrease the rates of the overall recurrence and bladder recurrence. Recently, Seisen *et al* observed that LNU was a significant predictor of the IRFS in their meta-analysis enrolling in six studies (HR 1.62; 95% CI: 1.18-2.22).(Seisen et al. 2015) After enrolling more available HRs extracted from multivariate or univariable Cox regression, our results showed there was no significant difference in IRFS between LNU and ONU management, different from the studies of Ni *et al* and Seisen *et al*. We thought the conclusion that LNU could improve the CSS should be interpreted cautiously, although this conclusion was consistent with the previous opinion of Ni *et al*.

Several limitations must be acknowledged in our meta-analysis. First, this meta-analysis was based on retrospective studies. Although all of these studies were of high quality (>5 stars) according to the modified Newcastle-Ottawa Scale, the intrinsic bias of cohort studies existed.

Next, the covariates controlled in the Cox regression analysis were different, which might introduce bias into our analysis. Finally, the time interval of the studies enrolled was more than 20 years. During this period, improvements in surgical techniques and medical materials should be considered. Additionally, these analyses did not include hand assisted laparoscopic nephroureterectomy because its relevant HR by Cox regression analysis for oncologic outcomes was reported in few literatures, and it is frequently deemed as an inferior approach compared with LNU or ONU in terms of the recurrence free survival and intravesical recurrence free survival rates.(Kitamura et al. 2014) Given the low incidence of UTUC, high quality level data were so scarce that our results should be interpreted cautiously. The oncological outcomes of LNU and ONU should be verified by prospective randomized controlled trials, especially for locally advanced disease.

Conclusion

Based on our meta-analysis of the current evidence, LNU could provide equivalent prognostic effects for upper tract urothelial carcinoma as ONU, and LNU had better results in the ExRFS and CSS. However, considering all eligible studies with the intrinsic bias of retrospective study design, the results should be interpreted with cautions, and prospective randomized controlled trials are still needed.

Table-1

Characteristics of the studies included in the systematic review

Table 1. Characteristics of the studies included in the systematic review

Study	Country	Duration	N of pts (ONU/LNU)	Age (yrs) (ORNU/LRNU)	Follow up (month) (ONU/LNU)	Outcomes	Approach of LNU	NOS	Adjusted factors
Favaretto 2010	USA	2002-2008	109/53	Md73 (IQR67-78) Md71 (IQR64-76)	Md23	UnRFS, IRFS	Mixed	6	Age, ASA, pT, Grade, pN, CIS, PBC
Fradet 2014	Canada	1990.1-2010.6	267/345	Md67 (IQR59-75)	Md24.8 (IQR7.69-56.76)	IRFS	NA	7	Age, Smoking, PH, Previous abdominal radiotherapy, DUM, CIS, TL, AC
Ito 2013	Japan	2005.12-2008.11	39/33	NA	R2.6-39.3	IRFS	RE	6	Sex, Age, TS, pT, UC, Grade, CIS, Histology type, AC
Kim 2015	Korea	1992-2012	271/100	Md64.7 (IQR57.7-70.8)	Md50.8 (IQR26.6-103.6)	OS,CSS, IRFS	TR	8	Age, ASA, PBC, UC, pT,Grade, LVI, Variant histology of urothelial carcinoma, TL, SM, AC Grade
Kitamura 2014	Japan	1995.4-2010.8	34/65	Md69 (R32-88) Md65 (R53-71)	Md70 (R6-192)	IRFS	Mixed	6	

Zou 2014	CHN	1999.1-2013.2	101/21	Mn63.7 (R35-80)	Md53 (R3-159)	IRFS, CSS	TR	7	Gender, PH, TS, TL, Size, Appearance, Necrosis, pT, Grade, Multifocality, CIS, SM, LVI
Yafi 2012	Canada	1990-/	591/46	Md68 (IQR61-75)	Md37 (IQR18-68)	ExRFS, CSS	NA	6	Age, Race, Gender, TL, pT, Grade, CIS, LVI, pN
Walton 2011	Multi central	1987- 2008	703/70	Md68 (IQR61-75)	Md34 (IQR15-65)	ExRFS, CSS	NA	7	Age, Gender, Race, PBC, DUM, TL, Grade, pT, pN, LVI, CIS
Taweemo nkongsap 2008	Thailan d	2001.4- 2007.1	29/31	Mn66.8 (R39-88) Mn63.8 (R26-79)	Mn27.9 (R3-63) Mn26.4 (R3-72)	UnRFS	RE	5	pT, Grade
Metcalfe 2012	Canada	1990- 2010	403/446	Mn69.7 (SD10.7)	Mn26.4 (R7.2-60)	UnRFS, OS	NA	8	Region, Age, Symptoms, TL, pT, Grade, CIS, PBC, NeoAC, AC, Salvage chemotherapy, Salvage radiation therapy, SM, Smoking, Previous abdominal RT, pN
Kume 2006	Japan	1996- 2003	28/13	Mn65.07 (SD9.46) Mn65.31 (SD10.69)	Mn55.7 (SD29.4) Mn34.2 (SD10.9)	IRFS	RE	6	Multiple tumors, pT, Grade, OT
Koda 2007	Japan	1995.1- 2005.8	27/29	Mn67.4 (SD11.3)	Mn46.2 (R 1-97)	IRFS	RE	6	Sex, Side, Age, pT, Grade, OT, AC,

				Mn71.4 (SD8.2)	Mn16.4 (R1-57.5)				PBC
Ploussard 2015	multice ntres	1989- 2012	2826/92 2	Md70 (IQR60-74)	Md32.7 (IQR13.6- 67.4)	IRFS, CSS	NA	7	Age, Sex, Ureter location, Multifocality, LN, DUM, pT, High grade, CIS, AC
Rieken 2014	mutice ntres	1987- 2007	2042/45 0	Md69.2 (IQR62-77)	Md36	ExRFS, OS,CSS	NA	5	Univariable Cox regression
Fairey 2013	Canada	1994- 2009	403/446	Md70.5 Md72.4 Mn68.3 (R27-97)	Md26.4 (IQR7.2-60)	UnRFS, OS,CSS	Mixed	7	Age, Sex, AC, pT, pN, Grade, SM
Capitanio 2009	mutice ntres	1987- 2007	979/270	Md69.8 (R60.9-76)	Md49	ExRFS, CSS	NA	7	Age, pT, pN, Grade, LVI, ECOG PS, pN, PBC, Previous endoscopy, CIS
Ariane 2012	France	1995- 2010	459/150	Md69.5 (R63-77)	Md27 (R10-48)	UnRFS, CSS,	TR	6	Gender, Age, ASA physical status, TL, pT, Grade, pN, LVI
Kobayas hi 2012	Japan	2005.1- 2009.4	151/137	Md71.4 (R32-89)	Md20.2 (R3.0-61.6)	IRFS	RE	6	TL, Time of ligation of the ureter, UC.
Terakawa 2008	Japan	2000.1- 2005.1 2	111/66	Mn71.3 (SD9.6)	Mn31 (R12.0- 80.5)	IRFS	RE	7	Age, TS, TL, Multifocality, OT, DUM, pT, Grade, pN, LVI, SM
Ishikawa 2010	Japan	1990- 2005	165/43	Md70 (R39-90)	Md8 (R2-105)	IRFS, CSS	RE	5	Univariable Cox regression
Xylinas 2013	France	1995- 2009	350/132	Mn69.2 (IQR60-76)	Mn39.5 (IQR25-60)	IRFS	NA	6	Age, Gender, TL, Multifocality, PBC, Endoscopic management, pT, Grade, CIS, LVI, pN

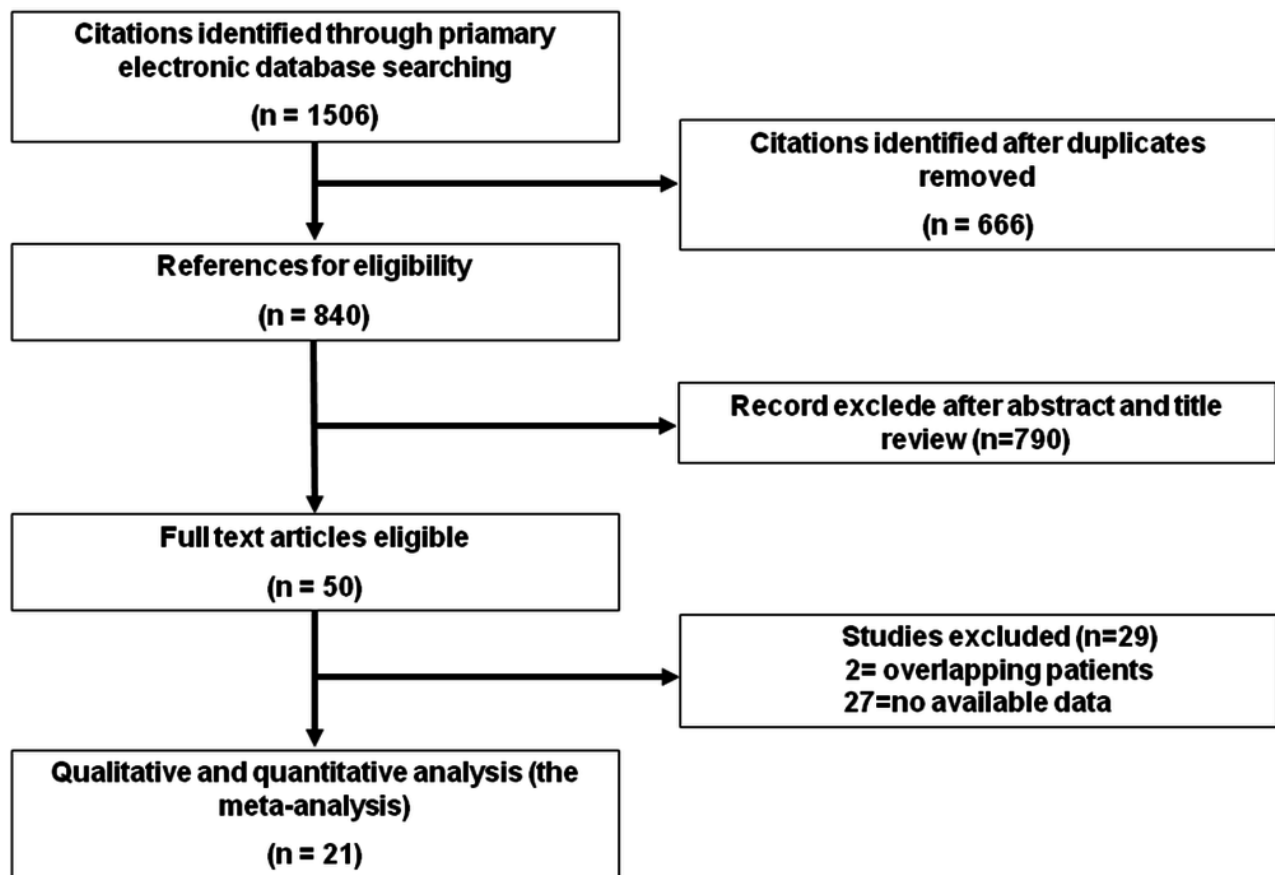

Abbreviations:

yrs - years; N of pts - number of patients; Mn - mean; Md - median; R - range; IQR - interquartile range; NA - not applicable; IRFS -intravesical recurrence free survival; ExRFS -extravesical recurrence free survival; UnRFS - unspecified recurrence free survival; OS - overall survival; CSS - cancer specific survival; RE - retroperitoneal; TR - transperitoneal ; NOS - Newcastle-Ottawa Scale; pT - pTstage; pN - pNstage; TL - tumor location; PH -previous hydronephrosis; DUM - distal ureter management; TS - tumor side; UC - urinary cytology; SM - surgical margin; PBC - previous bladder cancer; ASA - American Society of Anesthesiology physical status; AC - adjuvant chemotherapy; OT - operation time; CIS - carcinoma in situ; LVI - lymphovascular invasion; ECOG PS - Eastern Cooperative Oncology Group performance score.
