

Strategies for improved rhamnolipid production by *Pseudomonas aeruginosa* PA1

Alexandre Soares dos Santos, Nei Pereira Jr, Denise M G Freire

Rhamnolipids are biosurfactants with potential for diversified industrial and environmental uses. The present study evaluated three strategies for increasing the production of rhamnolipid-type biosurfactants produced by *Pseudomonas aeruginosa* strain PA1. The influence of pH, the addition of *P. aeruginosa* spent culture medium and the use of a fed-batch process were examined. The culture medium adjusted to pH 7.0 was the most productive. Furthermore, the pH of the culture medium had a measurable effect on the ratio of synthesized mono- and dirhamnolipids. At pH values below 7.3, the proportion of monorhamnolipids decreased from 45 to 24%. The recycling of 20% of the spent culture medium in where *P. aeruginosa* was grown up to the later stationary phase was responsible for a 100% increase in rhamnolipid volumetric productivity in the new culture medium. Finally, the use of fed-batch operation under conditions of limited nitrogen resulted in a 3.8-fold increase in the amount of rhamnolipids produced (2.9 g.L⁻¹ to 10.9 g.L⁻¹). These results offer promising pathways for the optimization of processes for the production of rhamnolipids.

Strategies for improved rhamnolipid production by *Pseudomonas aeruginosa* PA1

Abstract

Rhamnolipids are biosurfactants with potential for diversified industrial and environmental uses. The present study evaluated three strategies for increasing the production of rhamnolipid-type biosurfactants produced by *Pseudomonas aeruginosa* strain PA1. The influence of pH, the addition of *P. aeruginosa* spent culture medium and the use of a fed-batch process were examined. The culture medium adjusted to pH 7.0 was the most productive. Furthermore, the pH of the culture medium had a measurable effect on the ratio of synthesized mono- and dirhamnolipids. At pH values below 7.3, the proportion of monorhamnolipids decreased from 45 to 24%. The recycling of 20% of the spent culture medium in where *P. aeruginosa* was grown up to the later stationary phase was responsible for a 100% increase in rhamnolipid volumetric productivity in the new culture medium. Finally, the use of fed-batch operation under conditions of limited nitrogen resulted in a 3.8-fold increase in the amount of rhamnolipids produced (2.9 g L⁻¹ to 10.9 g L⁻¹). These results offer promising pathways for the optimization of processes for the production of rhamnolipids.

Keywords –

Introduction

Rhamnolipids are biodegradable biological surfactants. They present low toxicity and high resistance to extreme conditions of pH, salinity and temperature (Kesting *et al.*, 1996). Their surface properties, such as emulsification, dispersion, foaming, detergency, wetting and stabilization (Van Dyke *et al.*, 1993; Ishigami *et al.*, 1994; Desai and Banat, 1997; Bognolo, 1999), as well as their capacity for removing heavy metals (Torrens *et al.*, 1998; Lang and Wullbrandt, 1999; Kitamoto *et al.*, 2002) and their anticorrosive capacities (Araujo *et al.*, 2013), confer to these biosurfactants a variety of ecological (Rahman *et al.*, 2002) and commercial applications in the oil, pharmaceutical, food and chemical industries (Irfan-Maqsood and Seddiq-Shams, 2014; Randhawa *et al.*, 2014; Sinumvayo and Ishimwe, 2015).

Rhamnolipids are mainly produced by *Pseudomonas aeruginosa*, a Gram-negative bacterium that can be isolated from various habitats (water, soil or even plants). The control of rhamnolipid production in *P. aeruginosa* is achieved by a regulatory system called quorum sensing that is controlled by autoinducers such as acyl homoserine lactones and *Pseudomonas* quinolone signal molecule. These signaling molecules, paired with the LasR and RhIR regulators, initiate the expression of the enzymes involved in rhamnolipid synthesis (rhamnosyltransferases) (Ochsner *et al.*, 1994, 1995; Rahim *et al.*, 2001; Reis *et al.*, 2011).

Efforts should be oriented toward the optimization of processes for the production of biosurfactants that result in high productivity on a commercial scale so that they can compete with synthetic surfactants in terms of cost. One of the strategies that has been suggested in the literature is the limitation of nutrients (Desai and Banat, 1997; Chayabutra *et al.*, 2000), mainly nitrogen sources, as well as multivalent cations (Syldatk *et al.*, 1985; Glick *et al.*, 2010) and some anions (Mulligan *et al.*, 1989; Clarck *et al.*, 2010), as a condition necessary for stimulating

the synthesis of rhamnolipids by *P. aeruginosa*. In addition to nutritional modifications, changes in physical factors such as temperature and pH can also influence the synthesis of rhamnolipids by *P. aeruginosa* (Souza *et al.*, 2011; Jamal *et al.*, 2014). Another approach to the induction of the rhamnolipid synthesis is the use of exogenous or endogenous autoinducers (Ochsner and Reiser, 1995; Nakata *et al.*, 1998; Galkin *et al.*, 2014).

The aim of this work was to improve the cultivation conditions for the production of rhamnolipids by a strain of *Pseudomonas aeruginosa* isolated from a Brazilian petroleum-exploring environment. This study involved the investigation of the effect of a variation in the pH of the culture medium, the medium supplementation with recycled *P. aeruginosa* spent culture medium and evaluation of process carried on fed-batch operation.

Material and Methods

Inoculum

Pseudomonas aeruginosa PA1 (Santa Anna *et al.*, 2001) was maintained in a glycerol solution (10% v/v) at -80°C . The thawed strain sample was inoculated onto YPDA plates (yeast extract, 0.3%; peptone, 1.5%; dextrose, 0.1%; agar, 1.2%) at 30°C for 48 h. The growth of the inoculum was initiated by the addition of a loopful of cells from YPDA plates to a 1000 mL Erlenmeyer flask containing 300 mL of medium with the following composition (per liter): 1.0 g of NaNO_3 , 3.0 g of KH_2PO_4 , 7.0 g of K_2HPO_4 , 0.2 g of $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$, 5.0 g of yeast extract, 5.0 g of peptone, and 30 g of glycerol. *P. aeruginosa* was grown at 30°C and pH 7.0 in a rotary shaker at 170 rpm for 24 hours. Cells were harvested by centrifugation (10,000g for 30 minutes) and used as the inoculum.

Influence of pH on rhamnolipid production

The culture medium contained (per liter) 0.2 g of $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$, 1.38 g of NaNO_3 , and 30 g of glycerol. The pH of the culture medium was adjusted from 5.7 to 8.0 with $\text{KH}_2\text{PO}_4/\text{K}_2\text{HPO}_4$ buffer by varying the mole fraction of salt species without changing the concentration of total phosphate ion, which was maintained at 0.062 moles per liter. Six 500-mL Erlenmeyer flasks containing a working volume of 100 mL were prepared, inoculated with 0.12 g of cells (dry weight) and incubated at 30 °C in a rotary shaker at 170 rpm for 192 hours. Samples were removed at 24-hour intervals for the measurement of cell growth and rhamnolipid concentration.

Simple batch process supplemented with recycled *P. aeruginosa* spent culture medium

The culture medium was prepared with the following composition (per liter): 1.38 g of NaNO_3 , 3.0 g of KH_2PO_4 , 7.0 g of K_2HPO_4 , 0.2 g of $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$, and 30 g of glycerol. To each of five 500-mL Erlenmeyer flasks was added 100 mL of liquid medium supplemented with 1%, 5%, 10%, 15% or 20% (v/v) of cell-free spent culture supernatant from a 120 h-old *P. aeruginosa* PA1 culture. The control flask contained no spent culture medium. The flasks were inoculated with 0.05 g of cells (dry weight) and incubated at 30°C and pH 7.0 in a rotary shaker at 170 rpm for 200 hours. Aliquots (1.5 mL) were removed at 24-hour intervals for the assessment of cell growth and rhamnolipid production. The mass balance (carbon and nitrogen sources) present at the start of the culture process was adjusted, when necessary, to maintain the same C/N ratio and avoid undesirable side effect.

Fed-batch process: nitrogen and carbon feed

The culture medium contained (per liter) 3.0 g of KH_2PO_4 , 7.0 g of K_2HPO_4 , 0.2 g of $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$, 0.46 g of NaNO_3 , and 10.0 g of glycerol. The pH was adjusted to 7.0. Three 500-

mL Erlenmeyer flasks (A, B and C) were prepared containing 100 mL of the liquid medium. The flasks were inoculated with 0.2 g of cells (dry weight) and incubated at 30°C in a rotary shaker at 170 rpm for 240 hours. The frequency of addition of nutrients was a function of the amount of glycerol consumed in each flask. Flask A received 5 mL of a solution containing glycerol (200 g.L⁻¹) and sodium nitrate (9 g.L⁻¹) at each addition. Flask B received 5 mL of a solution containing only glycerol (200 g.L⁻¹), and flask C received 5 mL of sterile distilled water. Aliquots (1.5 mL) were removed at 24-hour intervals for the quantification of cell growth, nitrate and glycerol consumption and rhamnolipid production.

Thin-layer chromatography for analysis of rhamnolipid types

The rhamnolipids produced were extracted with ethyl acetate from acidified (pH 2.0) cell-free medium and analyzed by TLC on silica-gel-coated aluminum sheets (Macherey-Nagel®) using CHCl₃:CH₃OH:CH₃COOH (65:15:2) as the eluent (Schenk *et al.*, 1995). The separated zones were stained with orcinol-sulfuric acid reagent, followed by heating at 100 °C for 15 minutes. The stained plates were scanned, and the relative quantities of the spots corresponding to the monorhamnolipids and dirhamnolipids were determined by densitometry using Band Leader (Ma'ayan Aharoni) and Micronal Origin (Micronal Software, Inc) software to produce two dimensional chromatograms.

Determination of cell, rhamnolipid, glycerol and nitrate concentrations

Cell growth was assessed by measuring the absorbance at 500 nm, and the cell dry weight (g.L⁻¹) was determined using a standard calibration curve [ABS = 1.2595 x DW (g.L⁻¹) – R²=0.989], considered to be valid for absorbance values up to 0.6 OD. Rhamnolipid

quantification was achieved indirectly by measurement of the rhamnose concentration using the method of Dubois (1956) and was expressed as the rhamnolipid concentration using the factor 2.23 established by Kronemberger *et al.* (2008) by mass spectrometry measurements. A 0.5 mL volume of cell-free supernatant was mixed with 0.5 mL of 5% phenol solution and 2.5 mL of 98% sulfuric acid and incubated for 15 minutes before measuring the absorbance at 490 nm. The results were compared with the analytical curve for rhamnose. Glycerol was quantified by the GPO-POD enzymatic-colorimetric method using a kit for triglyceride determination from LaborLab® (Brazil). Nitrate was quantified through a colorimetric method using brucine sulfate (ACS, 2006). Briefly, 2 mL of 0.6 g.L⁻¹ brucine sulfate in sulfuric acid solution (80%) was added to 0.5 mL of sample, and the reaction mixture was heated in boiling water for 15 minutes. The reaction mixture was immediately cooled in an ice bath, and the absorbance was measured at 410 nm. The absorbance values were converted into concentration using an analytical curve for sodium nitrate.

Definition of process parameters utilized

The process parameters utilized to evaluate the progress of improvement strategies for rhamnolipid production are defined as follows. t_f : final time of process (h); t_i : initial time of process (h); Δt ($t_f - t_i$); P_f : final rhamnolipid concentration (g.L⁻¹); P_i : initial rhamnolipid concentration (g.L⁻¹); X_i : initial cell mass concentration (g.L⁻¹); X_f : final cell mass concentration (g.L⁻¹); S_f : final substrate concentration (g.L⁻¹); S_i : initial substrate concentration (g.L⁻¹); $\Delta Rhamnolipids$ ($P_f - P_i$); $\Delta Biomass$ ($X_f - X_i$); $\Delta Substrate$ ($S_i - S_f$); $Y_{P/X}$ ($\Delta Rhamnolipids \div \Delta Biomass$): yield of product synthesized per unit of cell mass produced (g.g⁻¹); $Y_{P/S}$ ($\Delta Rhamnolipids \div \Delta Substrate$): yield of product synthesized per unit of substrate consumed (g.g⁻¹)

149 $^{-1}$); Q_P ($\Delta Rhamnolipids \div \Delta t$): volumetric rhamnolipid production rate ($g.L^{-1}.h^{-1}$); $Q_{S(Gly)}$
 150 ($\Delta Substrate \div \Delta t$): volumetric glycerol consumption rate ($g.L^{-1}.h^{-1}$); $Q_{S(NO_3)}$ ($\Delta Substrate \div \Delta t$):
 151 volumetric nitrate consumption rate ($g.L^{-1}.h^{-1}$); q_P ($Y_{P/X} \times 1000 \div \Delta t$): specific rate of
 152 rhamnolipids synthesis ($mg.g^{-1}.h^{-1}$);

153

154 **Results and Discussion**

155 **Influence of pH on rhamnolipid synthesis**

156 The qualitative effect of pH on rhamnolipid synthesis was evaluated by thin layer
 157 chromatography. Densitometric analysis of mono- and dirhamnolipids performed by TLC
 158 (Figure 1) furnished relative migration values close to 0.8 for the monorhamnolipids and 0.5 for
 159 the dirhamnolipids. These values are in agreement with the migration rate of monorhamnolipids
 160 and dirhamnolipids observed by Schenk and collaborators (1995), who employed TLC analysis
 161 under the same conditions. Under the assay conditions, the more hydrophilic dirhamnolipids
 162 interact more strongly with the TLC (silica gel) stationary phase because of the presence of two
 163 rhamnose rings linked to lipid chain, whereas only one sugar ring exists in the
 164 monorhamnolipids species.

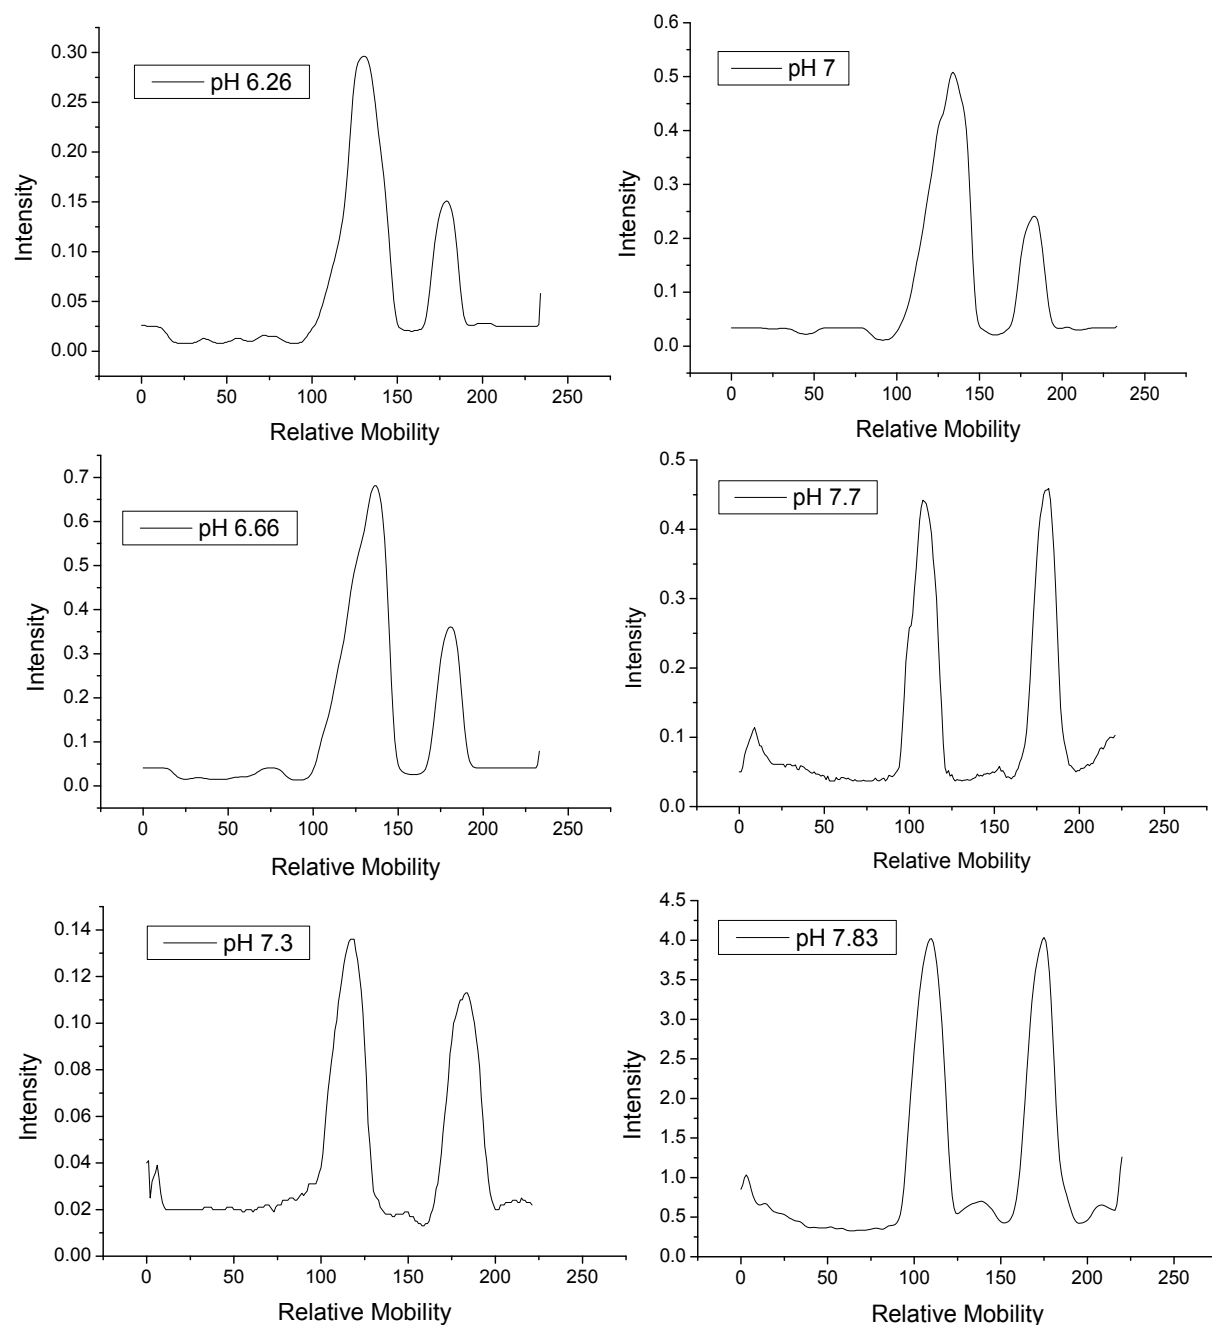

Figure 1: Densitometry of the thin layer chromatographs of rhamnolipids synthesized in culture medium at different pH values.

As is shown in the Table 1, the percentage of mono- and dirhamnolipids, determined by densitometry of TLC plates, varied as a function of the pH of the culture medium. For $\text{pH} \leq 7.0$, the amount of monorhamnolipids produced was lower than the amount of dirhamnolipids. On the other hand, at pH values higher than 7.0, the amounts of mono- and dirhamnolipids were approximately the same. Mata-Sandoval, Karns and Torrens (2001) showed that, at pH 6.26 and 7.0, dirhamnolipids were the most abundant molecular species in the mixtures of rhamnolipids synthesized by *P. aeruginosa* with corn oil as sole carbon source. However, they limited their experiments up to pH 7.0.

Table 1: Relative percentages of the rhamnolipid types synthesized as a function of the pH of the culture medium.

pH	Dirhamnolipids (%)	Monorhamnolipids (%)
6.26	74.35	25.65
6.66	75.35	24.65
7.00	76.41	23.59
7.30	55.25	44.75
7.70	51.66	48.34
7.83	52.75	47.25

It is possible that pH acts at a transcriptional level on the synthesis of one of the rhamnosyltransferases or on the synthesis of a specific glycolipid transporter channel, or even on the synthesis of L-rhamnose in *P. aeruginosa* (Olvera *et al.*, 1999). *Escherichia coli* represents an example in which various enzymes and periplasmic proteins are expressed in a pH-dependent mechanism (Stancik *et al.* 2002). In any case, the possibility of obtaining a product with distinct percentages of rhamnolipid types synthesized by the appropriate choice of pH allows for

different uses and applications for this natural formulation. Indeed, different rhamnolipid types or their mixtures present emulsifying activity, critical micellar concentration, hydrophobicity or bioavailabilities distinct from one other (Mata-Sandoval *et al.*, 1999). Costa *et al.* (2010), for example, observed different CMC, emulsifying activity and interfacial tension values when they compared two rhamnolipid preparations with distinct proportions of mono and dirhamnolipids species.

From the viewpoint of quantitative analysis, the effect of the pH of the culture medium on total rhamnolipid synthesis by *P. aeruginosa* PA1 demonstrated that the most productive pH value was 7.0 (Figure 2). Guerra-Santos *et al.* (1984) found that rhamnolipid production by *P. aeruginosa* cultivated in glucose peaked at pH values ranging from 6.0 to 6.5 and decreased at values higher than 7.0. Jamal *et al.* (2014) achieved a maximum rhamnolipids yield (4.44 g.L⁻¹) at a pH level of 7.33 using glycerol as the carbon source and NaNO₃ as the nitrogen source.

Figure 2: Variation of rhamnolipid synthesis as a function of the pH of the culture medium. The triangles and circles correspond to independent experiments.

Use of recycled *P. aeruginosa* spent culture medium

In this approach, the free cell spent cultivation medium, where *P. aeruginosa* was grown for a 120-hour period (later stationary phase), was used to induce rhamnolipid production. The presence of a mixture of acylated homoserine lactones (AHLs) and Pseudomonas quinolone signal (PQS) naturally secreted by *P. aeruginosa* in later stationary growth phase was reported by several researchers (Ochsner and Reiser, 1995; Pesci *et al.*, 1997; Reis *et al.*, 2011). This autoinducers are known to be responsible for the induction of the synthesis of rhamnolipids and other virulence factors in *P. aeruginosa* (Fuqua and Greenberg, 1998; Williams *et al.*, 2000; Diggle *et al.*, 2003).

The addition of spent medium containing endogenous autoinducers at the start of new *P. aeruginosa* cultures resulted in an increase in the yield of rhamnolipids synthesized per unit of substrate consumed ($Y_{P/X}$), as showed in Figure 3. The most significant differences among the $Y_{P/X}$ values were observed when the spent culture medium concentrations were changed from 1% to 5% and from 5 to 15% (Table 2).

Figure 3: Progress curves of yield coefficient $Y_{P/X}$ in culture medium with different supplemental proportions of 120 h-old *P. aeruginosa* spent culture medium.

The addition of spent culture medium to the new *P. aeruginosa* PA1 culture also increased the volumetric glycerol consumption rate ($Q_{S(Gly)}$) (Table 2). This fact suggests that the addition of endogenous autoinducers would also alter the metabolic rate of nutrients that, in the final analysis, would be coupled to the synthesis of the precursors for rhamnolipid production. The volumetric rhamnolipids production rate (Q_P) was also favored by the addition of endogenous autoinducers (Table 2).

Table 2: Process parameters of rhamnolipid production by *P. aeruginosa* PA1 in culture medium supplemented with different percentages of spent medium containing endogenous autoinducers.

Parameters	0%	1%	5%	10%	15%	20%
Δ Rhamnolipids (g L ⁻¹)	4.79	4.50	7.85	8.09	8.83	9.39
Δ Biomass (g L ⁻¹)	4.98	5.31	5.96	5.53	5.40	5.68
$Y_{P/X}$ (g g ⁻¹)	0.96	0.85	1.32	1.46	1.63	1.65
$Y_{P/S}$ (g g ⁻¹)	0.43	0.33	0.32	0.32	0.36	0.38
Q_P (g L ⁻¹ h ⁻¹)	0.027	0.026	0.044	0.047	0.051	0.054
Q_S (g L ⁻¹ h ⁻¹)	0.014	0.012	0.021	0.028	0.029	0.031

Δ Rhamnolipids: difference between final and initial rhamnolipid concentration; **Δ Biomass:** difference between final and initial cellular concentration; **$Y_{P/X}$:** yield of product synthesized per unit of cell mass produced; **$Y_{P/S}$:** yield of product synthesized per unit of substrate consumed; **Q_P :** volumetric rhamnolipids production rate; **$Q_{S(Gly)}$:** volumetric glycerol consumption rate.

The slopes calculated for each curve shown in Figure 3 using liner regression, called specific rate of rhamnolipids synthesis, were plotted against the log values of the spent culture medium concentration and are presented in Figure 4. This graph permits one to clearly observe that the increase in the production of rhamnolipids was due to an increase in the capacity of the microorganisms to synthesize rhamnolipids. These results suggest that the amount of spent culture medium added at the beginning of cultivation probably contributed to the increase in the synthesis of rhamnosiltransferases because the natural unfolding of the quorum sensing system, which is responsible for the transcriptional regulation of rhamnolipid synthesis in presence of endogenous autoinducers.

Figure 4: Relation between the specific rate of rhamnolipid synthesis and the addition of different proportions of 120 h-old *P. aeruginosa* spent culture medium.

Fed-batch strategy

The fed-batch operation is another possible strategy for increasing the production of rhamnolipids and was chosen to circumvent a possible negative effect, observed by Santa Anna *et al.* (2002), on the assimilation of nutrients when the culture medium contains glycerol concentrations higher than 3%. In addition, a process driven by fed-batch can control and maintain the nutrient limits already established as being favorable for rhamnolipid synthesis (Desai and Banat, 1997; Chayabutra *et al.*, 2000; Xavier *et al.*, 2011).

The consumption of nutrients during the fed-batch process was determined. In the control experiment, in which only water was fed to the medium, the carbon source (glycerol) and nitrogen source (NaNO_3) present at the beginning were totally consumed after approximately 50 and 24 hours of cultivation, respectively (Figures 5A and 5B).

Figure 5: Progress curve of glycerol (A) and nitrate (B) consumption during the fed-batch process using different feeding strategies. C and N – fed with carbon and nitrogen sources together. C - fed only with the carbon source. H₂O – fed with water instead of nutrients.

Although the consumption of the nitrogen source (NaNO₃) occurred in shorter time intervals than glycerol consumption (Figure 5A and 5B), the addition of a solution containing glycerol and nitrate was performed as a function of the consumption of the carbon source (Figure 5A). At 143 hours after the beginning of the process, the volumetric glycerol consumption rate decreased from 195 mg.L⁻¹.h⁻¹ to 162 mg.L⁻¹.h⁻¹. Because of this decay, only sodium nitrate was added at this time to the flask originally fed with carbon and nitrogen sources with the objective of maintaining the frequency of nitrate addition. The volumetric glycerol consumption rate ($Q_{S(\text{Gly})}$) was higher in the presence of a nitrogen source (Table 3). This fact becomes apparent when the curves of glycerol consumption are compared with one another, considering the process in which glycerol and nitrate are added together and the process in which only glycerol was added (Figure 5A). It is reasonable to assume that the enzymatic machinery involved in

glycerol metabolism, as well as in rhamnolipid biosynthesis, depends on the assimilation of nitrogen and its conversion into catalytic proteins.

Table 3: Process parameters observed in fed batch processes under different feeding conditions.

Parameters	C+N	C	H ₂ O
Δ Rhamnolipids (g L ⁻¹)	10.93	7.76	2.88
Δ Biomass (g L ⁻¹)	4.78	3.34	2.41
$Y_{P/X}$ (g g ⁻¹)	2.29	2.32	1.19
$Y_{P/S}$ (g g ⁻¹)	0.33	0.35	0.21
Q_P (g L ⁻¹ h ⁻¹)	0.047	0.033	0.027
$Q_{S(\text{Gly})}$ (g L ⁻¹ h ⁻¹)	0.168	0.073	0.197
$Q_{S(\text{NO}_3)}$ (g L ⁻¹ h ⁻¹)	0.027	0.027	0.027

Δ Rhamnolipids: difference between final and initial rhamnolipid concentration; **Δ Biomass:** difference between final and initial cellular concentration; **$Y_{P/X}$:** yield of product synthesized per unit of cell mass produced; **$Y_{P/S}$:** yield of product synthesized per unit of substrate consumed; **Q_P :** volumetric rhamnolipids production rate; **$Q_{S(\text{gly})}$:** volumetric glycerol consumption rate; **$Q_{S(\text{NO}_3)}$:** volumetric nitrate consumption rate. The parameters for the condition “H₂O” were calculated at 100 h of culture.

Ochsner *et al.* (1995) observed that the activity of the rhamnosyltransferase in *P. aeruginosa* during cultivation in a nitrogen-limiting medium containing glycerol as the carbon source was the highest at the beginning of the stationary phase and declined to zero in the late stationary phase. We suggest that exhaustion of the nitrogen source would limit not only cellular growth, but also the maintenance of the enzymatic machinery, mainly that involved in the metabolic pathways for rhamnolipid synthesis. In the present work, when the process of rhamnolipids production was simultaneously fed with carbon and nitrogen sources, a higher cell yield and volumetric productivity of rhamnolipids was achieved (Table 3).

On the basis of the feeding conditions, together with the control experiment (without feeding), one can conclude that the exhaustion of carbon and nitrogen sources interrupted the *P. aeruginosa* growth (Figure 6A) and the rhamnolipid synthesis (Figure 6B) sooner (at 72 hours after initiating the cultivation). On the other hand, feeding the system with only glycerol led to an improvement when compared with the simple batch (Figure 6A) and resulted in higher $Y_{p/X}$ and $Y_{p/S}$ values (Table 3). Furthermore, the feeding condition with both sources of nutrients (carbon and nitrogen) resulted in an even greater increase in both the biomass produced (Figure 6A) and the volumetric productivity, reaching a rhamnolipid production value 40% higher (Table 3)

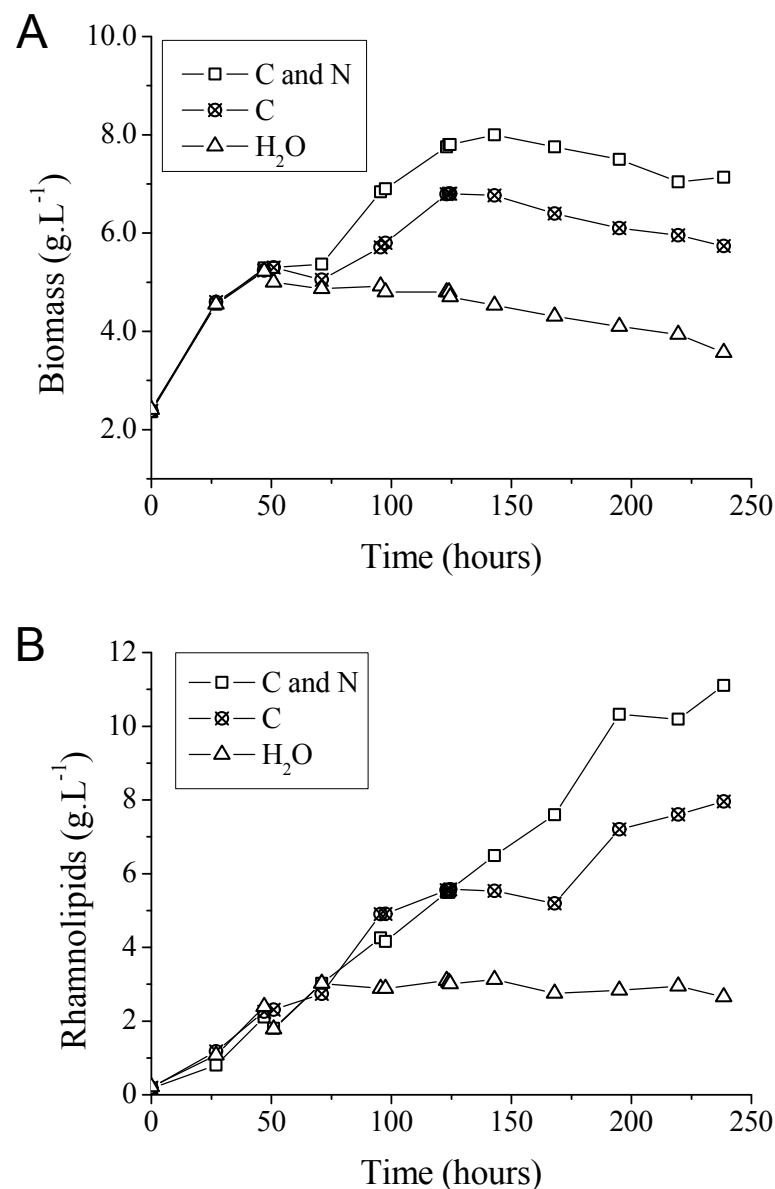

Figure 6: *P. aeruginosa* growth curves (A) and time course of rhamnolipid production (B) in the fed-batch process using different feeding strategies. C and N – fed with carbon and nitrogen sources together. C - fed only with the carbon source. H₂O – fed with water instead of nutrients.

After 125 hours from the start of the process, cell growth stopped in the fed-batch system with both sources of nitrogen and carbon and in the system only fed with carbon source (Figures

6A and 6B). It is possible that the limitation of other nutrients has occurred at this point, such as trace elements or oxygen. However, the production of rhamnolipids remained active mainly when fed simultaneously with nitrate and glycerol. This behavior characterizes a semi-growth associated profile.

Conclusion

In addition to demonstrating the most appropriate pH for stimulating the production of rhamnolipids by *P. aeruginosa* PA1, selective synthesis of different types of rhamnolipids caused by certain pH ranges appeared as an unexpected and timely result. The reutilization or recycling of culture medium containing endogenous autoinducers of the quorum sensing system produced by *P. aeruginosa* in new culture medium for the production of rhamnolipids was very effective in the induction of rhamnolipid synthesis. A two-fold increase in volumetric productivity was obtained using this strategy. The fed-batch experiment using the limitation of the carbon and nitrogen source was successful and could be employed along with an appropriate formulation of the cultivation conditions (micronutrients, pH, supplementary autoinducers)
