

## Acceptance of the German e-mental health portal [www.psychenet.de](http://www.psychenet.de): an online survey

Lisa Tlach, Juliane Thiel, Martin Härter, Sarah Liebherz, Jörg Dirmaier

**Background.** Taking into account the high prevalence of mental disorders and the multiple barriers to the use of mental health services, new forms of fostering patient information, involvement, and self-management are needed to complement existing mental health services. The study aimed at investigating acceptance regarding design and content of the e-mental health portal [www.psychenet.de](http://www.psychenet.de). **Methods.** An online cross-sectional survey was conducted between May 2013 and May 2015 using a self-administered questionnaire including items on perceived ease of use, perceived usefulness, attitude towards using, and perceived trust. Effects of different participants' characteristics on the portals' acceptance were analyzed. **Results.** The majority of the N=252 respondents suffered from mental disorders (n=139) or were relatives from persons with mental disorders (n=65). The portal was assessed as "good" or "very good" by 71% of the respondents. High levels of agreement (89-96%) were shown for statements on the perceived ease of use, the behavioral intention to use the portal, and the trustworthiness of the portal. Lower levels of agreement were shown for some statements on the perceived usefulness of the portals' content. There were no effects of different participants' characteristics on the perceived ease of use, the perceived usefulness, the attitude towards using the website and the perceived trust. **Discussion.** This survey provides preliminary evidence that the e-mental health portal [www.psychenet.de](http://www.psychenet.de) appears to be a usable, useful and trustworthy information resource for a broad target group. The behavioral usefulness of the portals' content might be improved by integrating more activating patient decision aids.

## 23 **Acceptance of the German e-mental health portal**

### 24 **www.psychenet.de: an online survey**

#### 25 **Abstract**

26 **Background.** Taking into account the high prevalence of mental disorders and the multiple  
27 barriers to the use of mental health services, new forms of fostering patient information,  
28 involvement, and self-management are needed to complement existing mental health services.  
29 The study aimed at investigating acceptance regarding design and content of the e-mental health  
30 portal [www.psychenet.de](http://www.psychenet.de).

31 **Methods.** An online cross-sectional survey was conducted between May 2013 and May 2015  
32 using a self-administered questionnaire including items on perceived ease of use, perceived  
33 usefulness, attitude towards using, and perceived trust. Effects of different participants'  
34 characteristics on the portals' acceptance were analyzed.

35 **Results.** The majority of the N=252 respondents suffered from mental disorders (n=139) or were  
36 relatives from persons with mental disorders (n=65). The portal was assessed as "good" or "very  
37 good" by 71% of the respondents. High levels of agreement (89-96%) were shown for statements  
38 on the perceived ease of use, the behavioral intention to use the portal, and the trustworthiness of  
39 the portal. Lower levels of agreement were shown for some statements on the perceived  
40 usefulness of the portals' content. There were no effects of different participants' characteristics  
41 on the perceived ease of use, the perceived usefulness, the attitude towards using the website and  
42 the perceived trust.

43 **Discussion.** This survey provides preliminary evidence that the e-mental health portal  
44 [www.psychenet.de](http://www.psychenet.de) appears to be a usable, useful and trustworthy information resource for a  
45 broad target group. The behavioral usefulness of the portals' content might be improved by  
46 integrating more activating patient decision aids.

## 47 **Introduction**

48 Over a third of the total EU population suffers from mental disorders with anxiety and mood  
49 disorders being the most frequent mental disorders (Wittchen et al. 2011). However, mental  
50 disorders are often not detected; only about one third of patients receives adequate treatment, and  
51 access to treatment is complicated by system-related barriers (Mack et al. 2014). In most  
52 epidemiological studies, service use of mentally ill people ranges between 2% to 18% (Wang et  
53 al. 2007). Given the structural problems of the mental health care system, new forms of fostering  
54 patient information, involvement, and self-management are needed to complement existing  
55 mental health services. Therefore the development of innovative treatment approaches that are  
56 available to a large population is recommended (Christensen & Petrie 2013).

## 57 **Bridging the Gap through Web-based Health Applications**

58 The Internet is widely seen as an effective complementary source for addressing these issues. As  
59 it reaches a large number of people, a reduction of barriers to the use of health services is  
60 facilitated by anonymity and high accessibility. It holds the opportunity to deliver interactive  
61 content that is tailored to the needs of the target group at comparatively low cost to a large  
62 number of users at the time, place and learning speed the individual user prefers (Arnberg et al.  
63 2014). Internationally, health services have increasingly expanded into online environments  
64 leading to the development of e-mental health services that are designed to complement, rather  
65 than replace existing mental health services. They hold the opportunity to reach people who live  
66 in remote areas or those with disabilities and without easy access to health care services  
67 (Anderson et al. 2013; Benavides-Vaello et al. 2013; Carrard et al. 2006). Furthermore, people

68 who refuse to seek out traditional services, especially those who wish to remain anonymous, may  
69 utilize e-mental health services (Townsend et al. 2012). E-health services may empower patients  
70 to participate in treatment choices and to take control and responsibility about their own health  
71 and care by improving access to services and information (Alpay et al. 2010; Alpay et al. 2011;  
72 Xie et al. 2013). A German national survey found that people increasingly take advantage of  
73 these opportunities (Eichenberg et al. 2013).

74 However, the quality and usability of mental health information on the World Wide Web is  
75 limited (Reavley & Jorm 2011) and the effectiveness of e-health interventions is limited by high  
76 attrition rates (Geraghty et al. 2013); most users visit health intervention websites only once  
77 (Brouwer et al. 2010; Verheijden et al. 2007). Additionally, reading levels of web-based patient  
78 materials are partially too high for the average user, not taking into account the large variance of  
79 health literacy in the population (Stossel et al. 2012). As persons with lower educational levels  
80 and respective persons with lower literacy levels might show less beneficial effect by using  
81 patient education materials (Goossens et al. 2014; Murphy et al. 2000), effects of educational  
82 levels on the acceptance – among other participants’ characteristics – should be accounted for in  
83 the interpretation of evaluation results.

#### 84 **The German E-mental Health Portal [www.psychenet.de](http://www.psychenet.de)**

85 A current project being part of the public-funded intersectoral research network *psychenet - the*  
86 *Hamburg Network for Mental Health* is aimed at developing and evaluating an e-mental health  
87 portal. With psychenet, the Federal Ministry of Education and Research contributes to  
88 strengthening healthcare regions in Germany by establishing new trans-sectoral cooperations and  
89 by implementing and evaluating selected health care innovations (Härter et al. 2012). The portal

90 www.psychenet.de is intended to increase the users' knowledge and to empower them to be  
91 active partners in medical decisions and the management of their mental strain.

92 In a first step, a basic version of the portal (comprising evidence-based patient information on a  
93 wide range of mental disorders and information about local treatment services) was developed to  
94 complement a region-wide awareness campaign on mental health in the metropolitan area of  
95 Hamburg that includes an award-winning media campaign (placards, cinema ads, radio ads) and  
96 specific educational projects (Härter et al. 2012). In order to obtain first evidence about the  
97 usability of the website, common web metrics were obtained via open source web analysis tools  
98 (e.g. Google Analytics). As a following project step, various modules have been developed for  
99 six of the most common mental disorders - depression, somatoform disorders, eating disorders,  
100 alcohol use disorders, psychotic disorders and anxiety disorders (Wittchen et al. 2011); e.g.  
101 patient decision aids (PtDAs), self-help tools, and screening tools. According to the International  
102 Patient Decision Aid Standard (IPDAS) collaboration criteria (Elwyn et al. 2006), the  
103 development of the modules has been based on a comprehensive mixed-methods needs  
104 assessment (focus groups, online-survey) among patients, relatives, and health care  
105 professionals. The technical development of the website has been commissioned by a  
106 professional web-design agency. The design and content of the portal and the results of the  
107 website using web metrics are described in detail elsewhere (Dirmaier et al. 2015). While the  
108 information about treatment services refer to the metropolitan area of Hamburg and the media  
109 campaign and specific health education projects were restricted to this region, the other tools  
110 (e.g. evidence based patient information (including fact sheets on several mental disorders and  
111 other basic facts concerning mental health as well as PtDAs) and screening tools) are not  
112 targeted specifically to this region.

113 The present study aimed at investigating acceptance regarding design and content of the basic  
114 version of the e-mental health portal [www.psychenet.de](http://www.psychenet.de) addressed at individuals with mental  
115 disorders, their relatives, service providers, and the interested public. The portal should be  
116 assessed through the following aspects of acceptance: 1) perceived ease of use, 2) perceived  
117 usefulness, 3) attitude towards using the website, 4) perceived trust, and 5) overall evaluation. A  
118 further aim was to explore effects of different participants' characteristics (sex, age, educational  
119 level, place of residence, experience with mental disorders, first time/multiple portal users,  
120 participation before or after the integration of the first PtDA) on the portals' acceptance.

## 121 **Methods**

### 122 **Design and participants**

123 The research team employed an online cross-sectional study using a self-administered survey.  
124 Online convenience sampling was conducted on our e-mental health portal [www.psychenet.de](http://www.psychenet.de).  
125 On each page of the portal, teasers were sited linking to a short invitation to participate in the  
126 survey. Users being interested were referenced to the survey that was arranged following detailed  
127 information about the studies' aim, procedure, and data security. Adult users (18 years or over)  
128 who gave written informed consent to participate (asked at the beginning of the questionnaire) as  
129 well as consent to data use (asked when participants had finished the questionnaire) were  
130 included in the analyses. There were no additional inclusion or exclusion criteria.

## 131 **Ethics Statement**

132 Approval for the study was obtained from the ethics committee of the Hamburg Medical  
133 Association (Process number: PV4157).

## 134 **Data collection**

135 The data were collected between May 2013 and May 2015 (24 months). A short, face-validated  
136 questionnaire comprising 33 items was developed for the study. The questionnaire comprised 3  
137 main sections: (1) baseline characteristics, (2) acceptance and usability, and (3) overall  
138 evaluation.

### 139 **Baseline characteristics**

140 Baseline characteristics were elicited using 4 items on sociodemographic variables (age, gender,  
141 education, postal code). Furthermore, 3 items were used to explore respondents' experience with  
142 mental disorders (4 options), how they accessed the website (3 options), and how they learned  
143 about the website (8 options including the option for a free answer). Previous internet use was  
144 explored on a 3-point scale (“(almost) every day”, “at least once a week”, “at least once a  
145 month”) and frequency of use of the portal was elicited on a 4-point scale (“first time”, “< 5  
146 times”, “> 5 times”, “> 10 times”).

### 147 **Acceptance and usability**

148 In order to assess the acceptance and the usability of the portal, respondents rated up to 22 items  
149 on a 4-point Likert scale (1=disagree, 2=somewhat disagree, 3=somewhat agree, 4=agree).  
150 Number of scale points and wording of the Likert scale were defined based on Chang (1994).  
151 According to a previous study on the acceptance of an e-health application (de Graaf et al. 2013),

152 participants were asked to rate statements covering 3 dimensions of the Technology Acceptance  
153 Model (TAM); see Davis (1989) and Chau & Hu (2002): *perceived ease of use* (8 items),  
154 *perceived usefulness* (10 items including 2 filter items for respondents being affected by mental  
155 disorders and 1 filter item for respondents being a relative of a person with mental disorders),  
156 and *attitude towards using* (2 items). The TAM dimensions were added by the dimension  
157 *perceived trust* (2 items) as it was shown to be a relevant quality criterion as seen by patients  
158 with long-term conditions and caregivers (Kerr et al. 2006) and it affects consumers acceptance  
159 of health technologies (Lemire et al. 2008; Wu et al. 2008).

## 160 **Overall evaluation**

161 In order to elicit an overall rating of the portal, respondents were asked to rate the portal on a 6-  
162 point scale based on the grading system used in German schools (1=very good, 2=good,  
163 3=satisfactory, 4=sufficient, 5=deficient, 6=insufficient). Finally, a facultative open field for  
164 comments and suggestions for improvements was provided. Before the questionnaire was used, it  
165 was pilot tested among 10 student assistants and research assistants not participating in this  
166 study.

## 167 **Data Analysis**

### 168 **Quantitative data analysis**

169 The professional web-based online survey software EFS Survey (Questback GmbH) was used  
170 for the electronic data collection. The statistical software package PASW Statistics 18 (SPSS  
171 Inc., Chicago IL) was used to analyze the data. Data were primarily evaluated by quantitative  
172 descriptive data analysis. In order to quantify responses, means, standard deviations, and

173 frequency distributions were calculated for each item on acceptance. Moreover, median, range,  
174 and frequency distribution were calculated for the overall rating.

175 To explore effects of different participants' characteristics (sex, age, educational level, place of  
176 residence, experience with mental disorders, first time/multiple portal users, participation before  
177 or after the integration of the first PtDA) on the acceptance and usability of the website, one-way  
178 analyses of variance (ANOVAs) were conducted for interval scaled variables (four dimensions  
179 of acceptance and usability) and Kruskal–Wallis H test for ordinal scaled variables (overall  
180 evaluation)..  $P < 0.05$  was considered to be significant for all analyses. The significance level was  
181 not adjusted as the tests served to generate hypotheses.

## 182 **Qualitative data analysis**

183 Qualitative data analysis was used to analyze the open field question using an inductive  
184 approach. Responses were categorized into five main categories: 1) negative appraisals, 2)  
185 positive appraisals, 3) suggestions for improvement, 4) not related to the website 5) no comment.  
186 Responses that included a number of themes were subdivided into various units and separately  
187 categorized. The coding was carried out by three members of the research team (LT, JT, SL).

## 188 **Results**

189 During the investigation period of 24 months, 14.000 to 36.000 visitors per month were  
190 registered through web analysis software. 1030 visitors of the portal started the web-based user  
191 survey. Of these, 314 completed the questionnaire (38.3% of those who agreed to participate).  
192 Finally, 252 participants gave their consent for the use of data (see Figure 1).

## 193 **Participants**

194 Of the 252 respondents, 55.2% (n=139) were affected from mental disorders. The respondents  
195 were predominantly female (64.3%, n=162), well-educated (middle or high educational level:  
196 75.8%, n=191) and had a mean age of 42.2 years (SD=15.0). The majority of the participants  
197 (90.5%, n=228) are using the internet (almost) every day. 57.5% of respondents (n=145) stated  
198 that they learned about the portal through online search for mental illnesses. 14.3% (n=36)  
199 learned about the portal through the projects' media campaign (cinema adverts, poster, YouTube  
200 channel, postcards). Of the total sample, 73.4% (n=185) reported that they were visiting the  
201 portal for the first time. For detailed baseline characteristics and frequency distributions of access  
202 paths and website use see Table 1.

## 203 **Acceptance of the portal**

204 Table 2 shows the percentage of users who agreed/disagreed to statements covering several  
205 aspects of acceptance, ordered separately for each dimension by the percentage of participants  
206 who agreed.

## 207 **Perceived ease of use**

208 89 to 96% of participants agreed with the particular statements concerning the perceived ease of  
209 use.

210 ANOVAs yielded no significant main effects of participants' characteristics for items associated  
211 with perceived ease of use.

**212 Perceived usefulness**

213 Concerning the perceived usefulness, the items concerning the usefulness of the content  
214 (interesting, new, appropriate amount of information, helpful, useful) gained the highest level of  
215 approval (79-93%). Lower levels of agreement from the perspective of the respondents living  
216 with mental disorders were shown for statements concerning the improvement of the  
217 communication with relatives or health care providers (51 respectively 60%). Concerning the  
218 affected peoples' relatives, 72% confirmed that they were now able to talk better about mental  
219 disorders with their relative being affected.

220 ANOVAs yielded no significant main effects of participants' characteristics for items associated  
221 with perceived usefulness.

**222 Attitude towards using the website**

223 Concerning the attitude towards using the website, more than 90% of the respondents agreed that  
224 they would recommend the website to others respectively would revisit the website if needed.

225 ANOVAs yielded no significant main effects of participants' characteristics for items associated  
226 with the attitude towards using the website.

**227 Perceived trust**

228 The majority of respondents (94-96%) agreed that the information on the website was  
229 trustworthy and that the information on the website was up to date.

230 For items associated perceived trust, ANOVAs yielded no significant main effects of  
231 participants' characteristics.

## 232 Overall evaluation

233 Almost three thirds of the respondents (71.4%, n=180) assessed the website as “very good”  
234 (n=60) or “good” (n=120). 21.0% of the participants (n=53) rated the website as “satisfactory”  
235 (n=39) or “sufficient” (n=14). Only 7.5% (n=19) marked the website as “deficient” (n=13) or  
236 “insufficient” (n=6). Overall, the ratings of the whole sample displayed a median of 2.0 (IQR=1-  
237 6).

238 Kruskal-Wallis H test revealed no significant effect of age, educational level, place of residence,  
239 frequency of portal use and the date of participation (before/after the integration of the first  
240 PtDA) on overall evaluation.

241 Women were more satisfied with the portal than men ( $p = 0.019$ ). The experience with mental  
242 disorders was also significantly associated with the overall evaluation ( $p = 0.037$ ) with the best  
243 rating in experts and the worst rating in people without experiences with mental disorders.

## 244 Qualitative analysis

245 The open field question was responded by 58 participants. The answers were subdivided into 64  
246 different statements. Seven participants explicitly mentioned that they had no comment. Five  
247 statements addressed the online survey and one statement addressed the general attitude towards  
248 people with mental disorders. All other statements refer directly to the e-health portal. There  
249 were 31 suggestions for improvement (e.g. the need for additional tools or topics, more in-depth  
250 information or regional expansion). Fifteen positive appraisals addressed knowledge and  
251 empowerment, the appropriate depth of information and the usefulness for newly diagnosed  
252 people among other topics. There were five negative appraisals concerning, for example,

253 incomprehensible information (too many technical terms) or the insufficient suitability for adults  
254 with bipolar disorders.

## 255 **Discussion**

256 As a consequence of multiple barriers in mental health service provision and access, a  
257 considerable proportion of persons living with mental disorders do not receive adequate  
258 treatment (Wang et al. 2007). Internationally, but not yet in Germany, mental health services  
259 have increasingly expanded into online environments leading to the development of e-mental  
260 health services. Within the framework of an intersectoral research network the e-health portal  
261 [www.psychenet.de](http://www.psychenet.de) addressed at individuals with mental disorders, their relatives and service  
262 providers has been developed recently. In this online study, acceptance regarding design and  
263 content of the portal was investigated.

264 In the present study, 252 users of the e-mental health portal [www.psychenet.de](http://www.psychenet.de) were included.  
265 Overall, the portal was assessed as “good” or “very good” by a substantial percentage of  
266 respondents . Moreover, high degrees of approval were found for statements on perceived ease  
267 of use. Comparable rates of agreement were found in an evaluation study on the usability of a  
268 web-based patient information system for individuals with severe mental health problems  
269 (Kuosmanen et al. 2010). Likewise, high levels of agreement were shown for statements on the  
270 behavioral intention to use the portal or to recommend it to others and regarding the  
271 trustworthiness of the portal. Lower levels of agreement were partly shown for some statements  
272 on the perceived usefulness. Concerning the usefulness of the portal in improving  
273 communication, relatives show higher levels of agreement than the respondents living with

274 mental disorders. In a recent study, Berk et al. (2013) reported comparatively higher levels of  
275 agreement regarding the usefulness of a website containing guidelines for caregivers of adults  
276 with bipolar disorder. Likewise, a study on the acceptance of a web-based e-health intervention  
277 for parents of children with infantile hemangiomas showed higher agreement rates (de Graaf et  
278 al. 2013). It is assumed, that the higher acceptance was due to the fact that the respective website  
279 was aimed at one target group (caregivers) and one narrowly defined topic (bipolar disorders,  
280 infantile hemangiomas). However, in an evaluation study on the user acceptance of a website for  
281 cancer patients with a more broad range of topics, higher levels of agreements were reported for  
282 ease of use compared to usefulness as it was also shown for the current study (Wallwiener et al.  
283 2010). Additionally, it should be noted that such comparisons are difficult to interpret as the  
284 studies probably varied substantially with respect to relevant characteristics such as ways of  
285 recruitment, response rates and users' experience with the respective portal.

286 Facing the fact that there were no effects of different participants' characteristics on the  
287 perceived ease of use, the perceived usefulness, the attitude towards using the website and the  
288 perceived trust, it can be assumed that the e-mental health portal is suitable for a broad range of  
289 users. Concerning the overall evaluation, there are some differences depending on users'  
290 characteristics: Women are more satisfied with the portal than men. As there are no sex  
291 differences regarding the other items, the difference results maybe from a differing answering  
292 behaviour regarding overall ratings. Additionally, the overall evaluation depends on the  
293 experience with mental disorders, indicating that experts are more pleased with the portal than  
294 affected people and relatives and all these three groups are more pleased than people without  
295 experiences with mental disorders. As the portal is targeted to experts, affected people and  
296 relatives, the last-mentioned result is not surprising.

297 Fortunately, the educational level had no influence on the acceptance and usability of the portal,  
298 suggesting that respondents with lower educational level are also able to benefit from the  
299 information presented at the portal. However, most respondents are well-educated and we do not  
300 know if this reflects the typical users' characteristics or if well-educated users are more likely to  
301 participate in the survey.

302 This analysis of acceptance offers preliminary evidence that the e-mental health portal  
303 [www.psychenet.de](http://www.psychenet.de) appears to be a usable, useful and trustworthy publically available  
304 information resource for adults living with mental illness, their relatives and experts working  
305 with mental disorders. The acceptance of the portal is further resembled by the high percentage  
306 of respondents that agreed their intention to recommend and to revisit the portal in case of  
307 necessity. The results of the web-analysis reported by Dirmaier et al. (2015) confirmed that the  
308 website is usable and highly accessed. Nonetheless, lower agreement levels concerning the  
309 usefulness of the portal on a behavioral level were observed. Thus, integrating content that  
310 supports active patient behavior regarding communication with relatives and with health care  
311 providers as provided by high quality patient decision aids (PtDAs) might improve the  
312 usefulness of the e-health portal. Previous analyses do not show an influence of the availability  
313 of the first decision aid on the acceptance of the portal. However, three of the four PtDAs were  
314 only available during the last weeks of the survey period. In order to further improve acceptance  
315 of the portal by targeting the offers of the portal to the users' needs, qualitative studies are  
316 requested to identify topics that are of high relevance to the users but have not been addressed  
317 until now.

318

## 319 **Limitations**

320 Due to methodological limitations the results of the study need to be interpreted with caution.  
321 First of all, convenience sampling was used by informing users about the survey without  
322 attracting attention and not actively recruiting. This resulted in a relatively small number of  
323 respondents – compared with the number of website users and the number of people who started  
324 the survey. - It is assumed, that respondents might have had an incentive to participate in the  
325 study as a consequence of being either particularly satisfied or dissatisfied with the offers  
326 presented at the portal. However, the positive ratings of the respondents suggest that they might  
327 have been motivated rather by their satisfaction than dissatisfaction with the system. However,  
328 high attrition rates are a common problem in online-surveys (Thielsch & Weltzin 2012).

329 As we do not know if the investigated sample was representative the results presented here might  
330 overestimate the acceptance of the portal. Future evaluations should be conducted using  
331 probability sampling methods to confirm the present findings.

332 As we used hardly any standardised instrument, the comparability of our results is limited.  
333 However, the questionnaire was developed based on widespread theories and evidence on  
334 acceptance of information technologies (Chau & Hu 2002; Davis 1989; Kerr et al. 2006; Lemire  
335 et al. 2008; Wu et al. 2008) and pilot tested among 10 participants. Furthermore, in order to  
336 provoke a definitive choice, no mid-point was provided. Due to the forced choice, the use of a 4-  
337 point scale might have led to a biased rating. However, Weijters, Cabooter & Schillewaert  
338 (2010) assumed that ambivalent or neutral respondents tend to rate negatively in the absence of a  
339 midpoint.

340 Moreover, as we used self-reported information on the respondents' experience with mental  
341 disorders, the validity of this information is limited.

## 342 **Conclusions**

343 Despite the methodological limitations, this study provides first evidence on the acceptance of  
344 the e-mental health portal [www.psychenet.de](http://www.psychenet.de). The results on the usefulness of the portal showed  
345 that there is still room for improvement. It is assumed that the portal empowers people with  
346 mental disorders and their relatives by facilitating to gather high-quality evidenced-based  
347 information about their illness, to rapidly find the right treatment services without great effort,  
348 and to prepare for health care provider contacts. Within the framework of this project, PtDAs for  
349 common mental disorders (i.e. depression, anxiety disorders, psychosis) supporting active user  
350 behavior were developed and implemented on the e-health portal [www.psychenet.de](http://www.psychenet.de) based on a  
351 comprehensive mixed-methods needs assessment study. In addition to the PtDAs, self-  
352 management tools are currently being evaluated.

## 353 **Acknowledgements**

354 psychenet is a project network supported by the German Federal Ministry of Education and  
355 Research in the region of Hamburg which consists of more than 100 scientific and medical  
356 institutions, counselling centers, the Senate and the Chamber of Commerce of the Free and  
357 Hanseatic City of Hamburg, companies, as well as patients' and relatives' associations (2011–  
358 2015). The vision of the project is to promote mental health today and in the future, concerning

359 early diagnosis and effective treatment of mental illnesses. For more information and a list of all  
360 partners please visit [www.psychenet.de](http://www.psychenet.de).
