

# Acceptance of the German e-mental health portal [www.psychenet.de](http://www.psychenet.de): an online survey

Lisa Tlach, Juliane Thiel, Martin Härter, Sarah Liebherz, Jörg Dirmaier

**Background.** Taking into account the high prevalence of mental disorders and the multiple barriers to the use of mental health services, new forms of fostering patient information, involvement, and self-management are needed to complement existing mental health services. The study aimed at investigating acceptance regarding design and content of the e-mental health portal [www.psychenet.de](http://www.psychenet.de). **Methods.** An online cross-sectional survey was conducted between May 2013 and May 2015 using a self-administered questionnaire including items on perceived ease of use, perceived usefulness, attitude towards using, and perceived trust. Effects of different participants' characteristics on the portals' acceptance were analyzed. **Results.** The majority of the N=252 respondents suffered from mental disorders (n=139) or were relatives from persons with mental disorders (n=65). The portal was assessed as "good" or "very good" by 71% of the respondents. High levels of agreement (89-96%) were shown for statements on the perceived ease of use, the behavioral intention to use the portal, and the trustworthiness of the portal. Lower levels of agreement were shown for some statements on the perceived usefulness of the portals' content. There were no effects of different participants' characteristics on the perceived ease of use, the perceived usefulness, the attitude towards using the website and the perceived trust. **Discussion.** This survey provides preliminary evidence that the e-mental health portal [www.psychenet.de](http://www.psychenet.de) appears to be a usable, useful and trustworthy information resource for a broad target group. The behavioral usefulness of the portals' content might be improved by integrating more activating patient decision aids.

# 23 Acceptance of the German e-mental health portal 24 www.psychenet.de: an online survey

## 25 Abstract

26 **Background.** Taking into account the high prevalence of mental disorders and the multiple  
27 barriers to the use of mental health services, new forms of fostering patient information,  
28 involvement, and self-management are needed to complement existing mental health services.  
29 The study aimed at investigating acceptance regarding design and content of the e-mental health  
30 portal [www.psychenet.de](http://www.psychenet.de).

31 **Methods.** An online cross-sectional survey was conducted between May 2013 and May 2015  
32 using a self-administered questionnaire including items on perceived ease of use, perceived  
33 usefulness, attitude towards using, and perceived trust. Effects of different participants'  
34 characteristics on the portals' acceptance were analyzed.

35 **Results.** The majority of the N=252 respondents suffered from mental disorders (n=139) or were  
36 relatives from persons with mental disorders (n=65). The portal was assessed as "good" or "very  
37 good" by 71% of the respondents. High levels of agreement (89-96%) were shown for statements  
38 on the perceived ease of use, the behavioral intention to use the portal, and the trustworthiness of  
39 the portal. Lower levels of agreement were shown for some statements on the perceived  
40 usefulness of the portals' content. There were no effects of different participants' characteristics  
41 on the perceived ease of use, the perceived usefulness, the attitude towards using the website and  
42 the perceived trust.

43 **Discussion.** This survey provides preliminary evidence that the e-mental health portal  
 44 [www.psychenet.de](http://www.psychenet.de) appears to be a usable, useful and trustworthy information resource for a  
 45 broad target group. The behavioral usefulness of the portals' content might be improved by  
 46 integrating more activating patient decision aids.

# 47 Introduction

48 Over a third of the total EU population suffers from mental disorders with anxiety and mood  
 49 disorders being the most frequent mental disorders (Wittchen et al. 2011). However, mental  
 50 disorders are often not detected; only about one third of patients receives adequate treatment, and  
 51 access to treatment is complicated by system-related barriers (Mack et al. 2014). In most  
 52 epidemiological studies, service use of mentally ill people ranges between 2% to 18% (Wang et  
 53 al. 2007). Given the structural problems of the mental health care system, new forms of fostering  
 54 patient information, involvement, and self-management are needed to complement existing  
 55 mental health services. Therefore the development of innovative treatment approaches that are  
 56 available to a large population is recommended (Christensen & Petrie 2013).

## 57 Bridging the Gap through Web-based Health Applications

58 The Internet is widely seen as an effective complementary source for addressing these issues. As  
 59 it reaches a large number of people, a reduction of barriers to the use of health services is  
 60 facilitated by anonymity and high accessibility. It holds the opportunity to deliver interactive  
 61 content that is tailored to the needs of the target group at comparatively low cost to a large  
 62 number of users at the time, place and learning speed the individual user prefers (Arnberg et al.  
 63 2014). Internationally, health services have increasingly expanded into online environments  
 64 leading to the development of e-mental health services that are designed to complement, rather  
 65 than replace existing mental health services. They hold the opportunity to reach people who live  
 66 in remote areas or those with disabilities and without easy access to health care services  
 67 (Anderson et al. 2013; Benavides-Vaello et al. 2013; Carrard et al. 2006). Furthermore, people

who refuse to seek out traditional services, especially those who wish to remain anonymous, may utilize e-mental health services (Townsend et al. 2012). E-health services may empower patients to participate in treatment choices and to take control and responsibility about their own health and care by improving access to services and information (Alpay et al. 2010; Alpay et al. 2011; Xie et al. 2013). A German national survey found that people increasingly take advantage of these opportunities (Eichenberg et al. 2013).

However, the quality and usability of mental health information on the World Wide Web is limited (Reavley & Jorm 2011) and the effectiveness of e-health interventions is limited by high attrition rates (Geraghty et al. 2013); most users visit health intervention websites only once (Brouwer et al. 2010; Verheijden et al. 2007). Additionally, reading levels of web-based patient materials are partially too high for the average user, not taking into account the large variance of health literacy in the population (Stossel et al. 2012). As persons with lower educational levels and respective persons with lower literacy levels might show less beneficial effect by using patient education materials (Goossens et al. 2014; Murphy et al. 2000), effects of educational levels on the acceptance – among other participants’ characteristics – should be accounted for in the interpretation of evaluation results.

## **The German E-mental Health Portal [www.psychenet.de](http://www.psychenet.de)**

A current project being part of the public-funded intersectoral research network *psychenet - the Hamburg Network for Mental Health* is aimed at developing and evaluating an e-mental health portal. With *psychenet*, the Federal Ministry of Education and Research contributes to strengthening healthcare regions in Germany by establishing new trans-sectoral cooperations and by implementing and evaluating selected health care innovations (Härter et al. 2012). The portal

www.psychenet.de is intended to increase the users' knowledge and to empower them to be active partners in medical decisions and the management of their mental strain.

In a first step, a basic version of the portal (comprising evidence-based patient information on a wide range of mental disorders and information about local treatment services) was developed to complement a region-wide awareness campaign on mental health in the metropolitan area of Hamburg that includes an award-winning media campaign (placards, cinema ads, radio ads) and specific educational projects (Härter et al. 2012). In order to obtain first evidence about the usability of the website, common web metrics were obtained via open source web analysis tools (e.g. Google Analytics). As a following project step, various modules have been developed for six of the most common mental disorders - depression, somatoform disorders, eating disorders, alcohol use disorders, psychotic disorders and anxiety disorders (Wittchen et al. 2011); e.g. patient decision aids (PtDAs), self-help tools, and screening tools. According to the International Patient Decision Aid Standard (IPDAS) collaboration criteria (Elwyn et al. 2006), the development of the modules has been based on a comprehensive mixed-methods needs assessment (focus groups, online-survey) among patients, relatives, and health care professionals. The technical development of the website has been commissioned by a professional web-design agency. The design and content of the portal and the results of the website using web metrics are described in detail elsewhere (Dirmaier et al. 2015). While the information about treatment services refer to the metropolitan area of Hamburg and the media campaign and specific health education projects were restricted to this region, the other tools (e.g. evidence based patient information (including fact sheets on several mental disorders and other basic facts concerning mental health as well as PtDAs) and screening tools) are not targeted specifically to this region.

The present study aimed at investigating acceptance regarding design and content of the basic version of the e-mental health portal [www.psychenet.de](http://www.psychenet.de) addressed at individuals with mental disorders, their relatives, service providers, and the interested public. The portal should be assessed through the following aspects of acceptance: 1) perceived ease of use, 2) perceived usefulness, 3) attitude towards using the website, 4) perceived trust, and 5) overall evaluation. A further aim was to explore effects of different participants' characteristics (sex, age, educational level, place of residence, experience with mental disorders, first time/multiple portal users, participation before or after the integration of the first PtDA) on the portals' acceptance.

## Methods

### Design and participants

The research team employed an online cross-sectional study using a self-administered survey. Online convenience sampling was conducted on our e-mental health portal [www.psychenet.de](http://www.psychenet.de). On each page of the portal, teasers were sited linking to a short invitation to participate in the survey. Users being interested were referenced to the survey that was arranged following detailed information about the studies' aim, procedure, and data security. Adult users (18 years or over) who gave written informed consent to participate (asked at the beginning of the questionnaire) as well as consent to data use (asked when participants had finished the questionnaire) were included in the analyses. There were no additional inclusion or exclusion criteria.

# **Ethics Statement**

Approval for the study was obtained from the ethics committee of the Hamburg Medical Association (Process number: PV4157).

# **Data collection**

The data were collected between May 2013 and May 2015 (24 months). A short, face-validated questionnaire comprising 33 items was developed for the study. The questionnaire comprised 3 main sections: (1) baseline characteristics, (2) acceptance and usability, and (3) overall evaluation.

# **Baseline characteristics**

Baseline characteristics were elicited using 4 items on sociodemographic variables (age, gender, education, postal code). Furthermore, 3 items were used to explore respondents' experience with mental disorders (4 options), how they accessed the website (3 options), and how they learned about the website (8 options including the option for a free answer). Previous internet use was explored on a 3-point scale (“(almost) every day”, “at least once a week”, “at least once a month”) and frequency of use of the portal was elicited on a 4-point scale (“first time”, “< 5 times”, “> 5 times”, “> 10 times”).

# **Acceptance and usability**

In order to assess the acceptance and the usability of the portal, respondents rated up to 22 items on a 4-point Likert scale (1=disagree, 2=somewhat disagree, 3=somewhat agree, 4=agree). Number of scale points and wording of the Likert scale were defined based on Chang (1994). According to a previous study on the acceptance of an e-health application (de Graaf et al. 2013),

participants were asked to rate statements covering 3 dimensions of the Technology Acceptance Model (TAM); see Davis (1989) and Chau & Hu (2002): *perceived ease of use* (8 items), *perceived usefulness* (10 items including 2 filter items for respondents being affected by mental disorders and 1 filter item for respondents being a relative of a person with mental disorders), and *attitude towards using* (2 items). The TAM dimensions were added by the dimension *perceived trust* (2 items) as it was shown to be a relevant quality criterion as seen by patients with long-term conditions and caregivers (Kerr et al. 2006) and it affects consumers acceptance of health technologies (Lemire et al. 2008; Wu et al. 2008).

## Overall evaluation

In order to elicit an overall rating of the portal, respondents were asked to rate the portal on a 6-point scale based on the grading system used in German schools (1=very good, 2=good, 3=satisfactory, 4=sufficient, 5=deficient, 6=insufficient). Finally, a facultative open field for comments and suggestions for improvements was provided. Before the questionnaire was used, it was pilot tested among 10 student assistants and research assistants not participating in this study.

## Data Analysis

### Quantitative data analysis

The professional web-based online survey software EFS Survey (Questback GmbH) was used for the electronic data collection. The statistical software package PASW Statistics 18 (SPSS Inc., Chicago IL) was used to analyze the data. Data were primarily evaluated by quantitative descriptive data analysis. In order to quantify responses, means, standard deviations, and frequency distributions were calculated for each item on acceptance. A total score for each

dimension (*perceived ease of use, perceived usefulness, attitude towards using, perceived trust*) was calculated by summing the scale's single items. Moreover, median, range, and frequency distribution were calculated for the overall rating.

To explore effects of different participants' characteristics (sex, age, educational level, place of residence, experience with mental disorders, first time/multiple portal users, participation before or after the integration of the first PtDA) on the acceptance and usability of the website, one-way analyses of variance (ANOVAs) were conducted for interval scaled variables (total scores of the four dimensions of acceptance and usability) and Kruskal–Wallis H test for ordinal scaled variables (overall evaluation).  $P < 0.05$  was considered to be significant for all analyses. The significance level was not adjusted as the tests served to generate hypotheses.

### Qualitative data analysis

Qualitative data analysis was used to analyze the open field question using an inductive approach. Responses were categorized into five main categories: 1) negative appraisals, 2) positive appraisals, 3) suggestions for improvement, 4) not related to the website 5) no comment. Responses that included a number of themes were subdivided into various units and separately categorized. The coding was carried out by three members of the research team (LT, JT, SL).

## Results

During the investigation period of 24 months, 14.000 to 36.000 visitors per month were registered through web analysis software. 1030 visitors of the portal started the web-based user survey and 819 gave consent to participate at the beginning of the questionnaire. Of these, 314 completed the questionnaire (38.3% of those who agreed to participate). Finally, 252 participants

gave their consent for the use of data at the end of the questionnaire, indicating that they answered the questionnaire in a meaningful way (e.g. did not answer the questions simply to have a look at the questionnaire) and that their data can be used for statistical analyses (see Figure 1).

## Participants

Of the 252 respondents, 55.2% (n=139) were affected from mental disorders. The respondents were predominantly female (64.3%, n=162), well-educated (middle or high educational level: 75.8%, n=191) and had a mean age of 42.2 years (SD=15.0). The majority of the participants (90.5%, n=228) are using the internet (almost) every day. 57.5% of respondents (n=145) stated that they learned about the portal through online search for mental illnesses. 14.3% (n=36) learned about the portal through the projects' media campaign (cinema adverts, poster, YouTube channel, postcards). Of the total sample, 73.4% (n=185) reported that they were visiting the portal for the first time. For detailed baseline characteristics and frequency distributions of access paths and website use see Table 1.

## Acceptance of the portal

Table 2 shows the percentage of users who agreed/disagreed to statements covering several aspects of acceptance, ordered separately for each dimension by the percentage of participants who agreed.

### Perceived ease of use

89 to 96% of participants agreed with the particular statements concerning the perceived ease of use.

216 ANOVAs yielded no significant main effects of participants' characteristics for items associated  
217 with perceived ease of use (see Table 3).

# **218 Perceived usefulness**

219 Concerning the perceived usefulness, the items concerning the usefulness of the content  
220 (interesting, new, appropriate amount of information, helpful, useful) gained the highest level of  
221 approval (79-93%). Lower levels of agreement from the perspective of the respondents living  
222 with mental disorders were shown for statements concerning the improvement of the  
223 communication with relatives or health care providers (51 respectively 60%). Concerning the  
224 affected peoples' relatives, 72% confirmed that they were now able to talk better about mental  
225 disorders with their relative being affected.

226 ANOVAs yielded no significant main effects of participants' characteristics for items associated  
227 with perceived usefulness (see Table 4).

# **228 Attitude towards using the website**

229 Concerning the attitude towards using the website, more than 90% of the respondents agreed that  
230 they would recommend the website to others respectively would revisit the website if needed.

231 ANOVAs yielded no significant main effects of participants' characteristics for items associated  
232 with the attitude towards using the website (see Table 5).

# **233 Perceived trust**

234 The majority of respondents (94-96%) agreed that the information on the website was  
235 trustworthy and that the information on the website was up to date.

236 For items associated perceived trust, ANOVAs yielded no significant main effects of  
237 participants' characteristics (see Table 6).

## 238 **Overall evaluation**

239 Almost three thirds of the respondents (71.4%, n=180) assessed the website as “very good”  
240 (n=60) or “good” (n=120). 21.0% of the participants (n=53) rated the website as “satisfactory”  
241 (n=39) or “sufficient” (n=14). Only 7.5% (n=19) marked the website as “deficient” (n=13) or  
242 “insufficient” (n=6). Overall, the ratings of the whole sample displayed a median of 2.0 (IQR=1-  
243 6).

244 Kruskal-Wallis H test revealed no significant effect of age, educational level, place of residence,  
245 frequency of portal use and the date of participation (before/after the integration of the first  
246 PtDA) on overall evaluation.

247 Women were more satisfied with the portal than men ( $p = 0.019$ ). The experience with mental  
248 disorders was also significantly associated with the overall evaluation ( $p = 0.037$ ) with the best  
249 rating in experts and the worst rating in people without experiences with mental disorders.

## 250 **Qualitative analysis**

251 The open field question was responded by 58 participants. The answers were subdivided into 64  
252 different statements. Seven participants explicitly mentioned that they had no comment. Five  
253 statements addressed the online survey and one statement addressed the general attitude towards  
254 people with mental disorders. All other statements refer directly to the e-health portal. There  
255 were 31 suggestions for improvement (e.g. the need for additional tools or topics, more in-depth  
256 information or regional expansion). Fifteen positive appraisals addressed knowledge and

empowerment, the appropriate depth of information and the usefulness for newly diagnosed people among other topics. There were five negative appraisals concerning, for example, incomprehensible information (too many technical terms) or the insufficient suitability for adults with bipolar disorders.

## Discussion

As a consequence of multiple barriers in mental health service provision and access, a considerable proportion of persons living with mental disorders do not receive adequate treatment (Wang et al. 2007). Internationally, but not yet in Germany, mental health services have increasingly expanded into online environments leading to the development of e-mental health services. Within the framework of an intersectoral research network the e-health portal [www.psychenet.de](http://www.psychenet.de) addressed at individuals with mental disorders, their relatives and service providers has been developed recently. In this online study, acceptance regarding design and content of the portal was investigated.

In the present study, 252 users of the e-mental health portal [www.psychenet.de](http://www.psychenet.de) were included. Overall, the portal was assessed as “good” or “very good” by a substantial percentage of respondents. Moreover, high degrees of approval were found for statements on perceived ease of use. Comparable rates of agreement were found in an evaluation study on the usability of a web-based patient information system for individuals with severe mental health problems (Kuosmanen et al. 2010). Likewise, high levels of agreement were shown for statements on the behavioral intention to use the portal or to recommend it to others and regarding the trustworthiness of the portal. Lower levels of agreement were partly shown for some statements

on the perceived usefulness. Concerning the usefulness of the portal in improving communication, relatives show higher levels of agreement than the respondents living with mental disorders. In a recent study, Berk et al. (2013) reported comparatively higher levels of agreement regarding the usefulness of a website containing guidelines for caregivers of adults with bipolar disorder. Likewise, a study on the acceptance of a web-based e-health intervention for parents of children with infantile hemangiomas showed higher agreement rates (de Graaf et al. 2013). It is assumed, that the higher acceptance was due to the fact that the respective website was aimed at one target group (caregivers) and one narrowly defined topic (bipolar disorders, infantile hemangiomas). However, in an evaluation study on the user acceptance of a website for cancer patients with a more broad range of topics, higher levels of agreements were reported for ease of use compared to usefulness as it was also shown for the current study (Wallwiener et al. 2010). Additionally, it should be noted that such comparisons are difficult to interpret as the studies probably varied substantially with respect to relevant characteristics such as ways of recruitment, response rates and users' experience with the respective portal.

Facing the fact that there were no effects of different participants' characteristics on the perceived ease of use, the perceived usefulness, the attitude towards using the website and the perceived trust, it can be assumed that the e-mental health portal is suitable for a broad range of users. Concerning the overall evaluation, there are some differences depending on users' characteristics: Women are more satisfied with the portal than men. As there are no sex differences regarding the other items, the difference results maybe from a differing answering behavior regarding overall ratings. Additionally, the overall evaluation depends on the experience with mental disorders, indicating that experts are more pleased with the portal than affected people and relatives and all these three groups are more pleased than people without

experiences with mental disorders. As the portal is targeted to experts, affected people and relatives, the last-mentioned result is not surprising.

Fortunately, the educational level had no influence on the acceptance and usability of the portal, suggesting that respondents with lower educational level are also able to benefit from the information presented at the portal. However, most respondents are well-educated and we do not know if this reflects the typical users' characteristics or if well-educated users are more likely to participate in the survey.

This analysis of acceptance offers preliminary evidence that the e-mental health portal [www.psychenet.de](http://www.psychenet.de) appears to be a usable, useful and trustworthy publically available information resource for adults living with mental illness, their relatives and experts working with mental disorders. The acceptance of the portal is further resembled by the high percentage of respondents that agreed their intention to recommend and to revisit the portal in case of necessity. The results of the web-analysis reported by Dirmaier et al. (2015) confirmed that the website is usable and highly accessed. Nonetheless, lower agreement levels concerning the usefulness of the portal on a behavioral level were observed. Thus, integrating content that supports active patient behavior regarding communication with relatives and with health care providers as provided by high quality patient decision aids (PtDAs) might improve the usefulness of the e-health portal. Previous analyses do not show an influence of the availability of the first decision aid on the acceptance of the portal. However, three of the four PtDAs were only available during the last weeks of the survey period. In order to further improve acceptance of the portal by targeting the offers of the portal to the users' needs, qualitative studies are requested to identify topics that are of high relevance to the users but have not been addressed until now.

324

## 325 **Limitations**

326 Due to methodological limitations the results of the study need to be interpreted with caution.  
 327 First of all, convenience sampling was used by informing users about the survey without  
 328 attracting attention and not actively recruiting. This resulted in a relatively small number of  
 329 respondents – compared with the number of website users and the number of people who started  
 330 the survey. It is assumed, that respondents might have had an incentive to participate in the study  
 331 as a consequence of being either particularly satisfied or dissatisfied with the offers presented at  
 332 the portal. However, the positive ratings of the respondents suggest that they might have been  
 333 motivated rather by their satisfaction than dissatisfaction with the system. However, high  
 334 attrition rates are a common problem in online-surveys (Thielsch & Weltzin 2012).

335 As we do not know if the investigated sample was representative (e.g. if the completers represent  
 336 the typical users' characteristics) the results presented here might overestimate the acceptance of  
 337 the portal. Most non-completers (46% of the people who started the questionnaire) discontinued  
 338 the questionnaire during the first page (introduction), another 9% of the non-completers  
 339 discontinued on the second page (informed consent to participate). When it came to the questions  
 340 concerning the acceptance and the usability of the portal, further 11% discontinued, maybe due  
 341 to the complex matrix character of these questions. The other non-completers discontinued at  
 342 other pages. Future evaluations should be conducted using probability sampling methods to  
 343 confirm the present findings. As we used hardly any standardised instrument, the comparability  
 344 of our results is limited. However, the questionnaire was developed based on widespread theories  
 345 and evidence on acceptance of information technologies (Chau & Hu 2002; Davis 1989; Kerr et

al. 2006; Lemire et al. 2008; Wu et al. 2008) and pilot tested among 10 participants. Furthermore, in order to provoke a definitive choice, no mid-point was provided. Due to the forced choice, the use of a 4-point scale might have led to a biased rating. However, Weijters, Cabooter & Schillewaert (2010) assumed that ambivalent or neutral respondents tend to rate negatively in the absence of a midpoint.

Moreover, as we used self-reported information on the respondents' experience with mental disorders, the validity of this information is limited.

## Conclusions

Despite the methodological limitations, this study provides first evidence on the acceptance of the e-mental health portal [www.psychenet.de](http://www.psychenet.de). The results on the usefulness of the portal showed that there is still room for improvement. It is assumed that the portal empowers people with mental disorders and their relatives by facilitating to gather high-quality evidenced-based information about their illness, to rapidly find the right treatment services without great effort, and to prepare for health care provider contacts. Within the framework of this project, PtDAs for common mental disorders (i.e. depression, anxiety disorders, psychosis) supporting active user behavior were developed and implemented on the e-health portal [www.psychenet.de](http://www.psychenet.de) based on a comprehensive mixed-methods needs assessment study. In addition to the PtDAs, self-management tools are currently being evaluated.

## Acknowledgements

366 *psychnet* is a project network supported by the German Federal Ministry of Education and  
 367 Research in the region of Hamburg which consists of more than 100 scientific and medical  
 368 institutions, counselling centers, the Senate and the Chamber of Commerce of the Free and  
 369 Hanseatic City of Hamburg, companies, as well as patients' and relatives' associations (2011–  
 370 2015). The vision of the project is to promote mental health today and in the future, concerning  
 371 early diagnosis and effective treatment of mental illnesses. For more information and a list of all  
 372 partners please visit [www.psychnet.de](http://www.psychnet.de).
