Design and validation of a next generation sequencing assay for hereditary *BRCA1* and *BRCA2* mutation testing

Hyunseok P. Kang, Jared R Maguire, Clement S Chu, Imran S. Haque, Henry Lai, Rebecca Mar-Heyming, Kaylene Ready, Valentina S. Vysotskaia, Eric A. Evans

Hereditary breast and ovarian cancer syndrome, caused by a germline pathogenic variant in the *BRCA1* or *BRCA2* (*BRCA1/2*) genes, is characterized by an increased risk for breast, ovarian, pancreatic and other cancers. Identification of those who have a *BRCA1/2* mutation is important so that they can take advantage of genetic counseling, screening, and potentially life-saving prevention strategies. We describe the design and analytic validation of the Counsyl Inherited Cancer Screen, a next-generation-sequencing-based test to detect pathogenic variation in the *BRCA1* and *BRCA2* genes. We demonstrate that the test is capable of detecting single-nucleotide variants (SNVs), short insertions and deletions (indels), and copy-number variants (CNVs, also known as large rearrangements) with zero errors over a 114-sample validation set consisting of samples from cell lines and deidentified patient samples, including 36 samples with *BRCA1/2* pathogenic germline mutations.

12 **ABSTRACT**

14 Hereditary breast and ovarian cancer syndrome, caused by a germline pathogenic variant
15 in the *BRCA1* or *BRCA2* (*BRCA1/2*) genes, is characterized by an increased risk for
16 breast, ovarian, pancreatic and other cancers. Identification of those who have a *BRCA1/2*
17 mutation is important so that they can take advantage of genetic counseling, screening,
18 and potentially life-saving prevention strategies. We describe the design and analytic
19 validation of the Counsyl Inherited Cancer Screen, a next-generation-sequencing-based
20 test to detect pathogenic variation in the *BRCA1* and *BRCA2* genes. We demonstrate that
21 the test is capable of detecting single-nucleotide variants (SNVs), short insertions and
22 deletions (indels), and copy-number variants (CNVs, also known as large
23 rearrangements) with zero errors over a 114-sample validation set consisting of samples
24 from cell lines and deidentified patient samples, including 36 samples with *BRCA1/2*
25 pathogenic germline mutations.

26
27
28 **INTRODUCTION**
29
30 Hereditary breast and ovarian cancer syndrome (HBOC) is associated with mutations in
31 tumor suppressor genes *BRCA1* and *BRCA2*. Genetic analysis for individuals who are at
32 risk for HBOC has become widely accepted. Several professional organizations and
33 expert panels, including the National Comprehensive Cancer Network (NCCN) (National
34 Comprehensive Cancer Network, 2014), the American Society of Clinical Oncology
35 (ASCO) (Robson et al., 2010), the American Society of Human Genetics (ASHG) (The
36 American Society of Human Genetics, 1994), the American College of Medical Genetics
37 and Genomics (ACMG) (Hampel et al., 2015), the National Society of Genetic
38 Counselors (NSGC) (Hampel et al., 2015), the U.S. Preventive Services Task Force
39 (USPSTF) (Nelson et al., 2014), the Society of Gynecologic Oncologists (SGO)
40 (Lancaster et al., 2007), and the European Society for Medical Oncology (ESMO)
41 (Balmaña et al., 2011) have developed clinical criteria and practice guidelines for
42 identifying individuals who may benefit from *BRCA1* or *BRCA2* mutation testing. In
43 general, personalized risk assessment, genetic counseling, and often *BRCA1/2* testing and
44 management are recommended for individuals with a significant personal and/or family
45 history of breast, ovarian, pancreatic and/or prostate cancer.
46

47 As suggested by various guidelines, individuals identified with
48 *BRCA1* or *BRCA2* mutation are at significantly increased risk for breast, ovarian,
49 prostate, pancreatic and possibly other cancers: a 12% general population risk for breast
50 cancer rises to 50-80% for *BRCA1* mutation carriers or 40-70% for *BRCA2* mutation
51 carriers (Petrucelli, Daly & Feldman, 2015). Screening for *BRCA* mutations is of great
52 significance for breast and ovarian cancer prevention and early detection. Recommended
53 risk-reducing options include increased screening, chemoprevention and/or prophylactic
54 surgery (Balmaña et al., 2011; Hampel et al., 2015; Lancaster et al., 2007; National
55 Comprehensive Cancer Network, 2014; Nelson et al., 2014; Robson et al., 2010;
56 Statement of the American Society of Human Genetics on genetic testing for breast and
57 ovarian cancer predisposition, 1994). Table 1 summarizes these options and their effect
58 on cancer risks.
59
60 Genetic testing for *BRCA1/2* mutation status has the potential to offer multiple benefits.
61 However, 20-73% of mutation carriers may not be identified by current guidelines (Alsop
62 et al., 2012; Brozek et al., 2012; Frank et al., 2002; Kang et al., 2014; Norquist et al.,
63 2013) or only meet current guidelines once they are diagnosed with ovarian cancer or
64 early onset breast cancer, resulting in some researchers to call for more inclusive
65 guidelines or even population screening (Finch et al., 2014; Gabai-Kapara et al., 2014;
66 Metcalfe et al., 2013).
67
68 Next-generation sequencing (NGS) technologies offer higher throughput and lower per-
69 base cost as compared to legacy approaches such as Sanger sequencing. Although
70 researchers have described technical questions regarding analytical performance for
71 classes of variants that are considered to be challenging for NGS (Harismendy et al.,
72 2009), these refer to technologies that are several years old. Several laboratories have
73 recently reported applying a NGS approach for diagnostic testing of mutations in the
74 *BRCA1/2* genes or multigene panels that include the *BRCA1* and *BRCA2* genes (Bosdet et
75 al., 2013; Chong et al., 2014; Judkins et al., 2015; Lincoln et al., 2015; Strom et al.,
76 2015). They performed a comparison of data analyses including independent and blind
77 evaluation as well as power estimation of the new NGS methodologies in comparison to
78 Sanger sequencing and demonstrated the very high accuracy of the NGS methods (Bosdet
79 et al., 2013; Chong et al., 2014; Judkins et al., 2015; Lincoln et al., 2015; Strom et al.,
80 2015).
81
82 The aim of the present study was to evaluate analytical sensitivity and specificity of the
83 Counsyl Inherited Cancer Screen (ICS), an NGS-based test for *BRCA1/2* testing. We
84 followed ACMG guidelines for analytical validation of NGS methods and platforms
85 (Rehm et al., 2013). The test also adheres to these guidelines for interpretation and
86 reporting of detected variants. Here, we report the results from a validation set of 114 cell
87 line and patient DNA samples, in which we demonstrate 100% concordance with
88 reference data or orthogonal assays.
89
90
91 **MATERIALS AND METHODS**
92

DNA Samples

The Counsyl Inherited Cancer Screen validation study was conducted by testing three classes of samples: a) deidentified blood samples (N=57), b) deidentified paired blood and saliva samples (7 pairs), and c) genomic DNA reference materials obtained from Coriell (N=57), including the well-characterized NA12878 sample from HapMap/1000 Genomes and 15 samples from the BIC *BRCA1/BRCA2* Mutation Panel (Tables 2 and Supplemental Table 1). The protocol for this study was approved by Western Institutional Review Board (IRB number 1145639) and complied with the Health Insurance Portability and Accountability Act (HIPAA). The information associated with patient samples was de-identified in accordance with the HIPAA Privacy Rule. A waiver of informed consent was requested and approved by the IRB.

Test Design

The reportable range of the test is all coding exons of *BRCA1 (*NM_007294.3) and *BRCA2* (NM_000059.3), 20 bp into the introns from intron/exon junctions, and selected intronic and untranslated regions where pathogenic variants have been reported in the literature (Supplemental Table 2).

Next Generation Sequencing

DNA from a patient's blood or saliva sample is isolated, quantified by a Picogreen fluorescence assay and then fragmented to 200-1000 bp by sonication. The fragmented DNA is converted to an adapter-ligated sequencing library by end repair, A tailing, and barcoded adapter ligation; samples are multiplexed and identified by molecular barcodes. Hybrid capture-based enrichment with 40-mer oligonucleotides (Integrated DNA Technologies, Coral, IL) complementary to *BRCA1/2* targeted regions is performed on these multiplexed samples. Next generation sequencing of the selected targets is performed with sequencing-by-synthesis on the Illumina HiSeq 2500 instrument to mean sequencing depth of ~500x. All target nucleotides were required to be covered with a minimum depth of 20 reads.

Bioinformatics Processing

Generated sequence reads are aligned to the hg19 human reference genome using the BWA-MEM algorithm (Li, 2013), which also trims sequencing adapters. Automated statistical analysis is used to identify and genotype single-nucleotide variants (SNVs) and short insertions and deletions (indels) following methods in GATK 1.6 and FreeBayes (Garrison & Marth, 2012; McKenna et al., 2010). The calling algorithm for copy number variants (insertions or deletions longer than 100bp) is described below. All SNVs, indels, and large deletions/duplications within the reportable range are analyzed and classified by the method described in the section "Variant Classification". All reportable calls are reviewed by licensed clinical laboratory personnel.

CNV Calling Algorithm

Our method for CNV calling is based on high-resolution depth of coverage analysis and performed in a manner similar to that successfully used by other groups (Nord et al., 2011; Judkins et al., 2015; Lincoln et al., 2015).

138   Analysis is performed on a per-lane basis. The region of interest for the assay is grouped
139   into a number of regions for which copy number is counted (e.g., exons); each exon is
140   considered independently and with no smooth (e.g. HMM). Define matrix $d_{i,j}$ to be the
141   matrix containing the number of reads from sample i overlapping with region j.

142   This matrix must be normalized. To protect against normalization issues due to individual
143   samples with very large CNVs (such as a whole-gene deletion), we generate a
144   normalization matrix $n_{i,j}$ by removing the highest variance probes from the total data
145   set D via the invariant set method described in (Li & Hung Wong, 2001). The data
146   matrix d is then normalized in two steps:

147

148    $d'_{i,j} = d_{i,j} / \text{mean}(n_{i,j} \text{ for all } j)$
149    $d''_{i,j} = d'_{i,j} / \text{mean}(n_{i,j} \text{ for all } i)$

150

151   For each putative CNV j in sample i, a hypothetical copy number and corresponding Z-
152   score is computed:

153

154    $c_{i,j} = 2 * d''_{i,j}$
155    $z_{i,j} = (d''_{i,j} - \text{mean}(d''_{i,j} \text{ for all } i)) / \text{stdev}(d''_{i,j} \text{ for all } i)$

156

157   A CNV call is considered confidently non-reference if $\text{abs}(z) \geq 4$ and the estimate c is
158   <1.2 or >2.8.

159

160   **Assay Quality Metrics**
161   To ensure the quality of the results obtained from the Counsyl Inherited Cancer Screen,
162   documentation and QC systems (Supplemental Table 3) were developed in the Counsyl
163   CLIA (Clinical Laboratory Improvement Amendments)-certified laboratory. Ancillary
164   quality-control metrics, including amount of DNA recovered from a specimen
165   (>=18ng/ul), fraction of sample contamination (<5%), unreliable GC bias, read qualities
166   (percent Q30 bases per Illumina specifications), depth of coverage (per base target
167   coverage >20x), are computed on the final output and used to exclude and re-run failed
168   samples.

169

170   **Variant Classification**
171   Variants are classified according to the ACMG Standards and Guidelines for the
172   Interpretation of Sequence Variants (American College of Medical Genetics and
173   Genomics, 2015). All variants that are known or predicted to be pathogenic are reported;
174   patients and providers have an option to have variants of uncertain significance reported
175   as well. Final variant classifications are regularly uploaded to ClinVar.

176

177   **Statistical Analysis**
178   Validation metrics were defined as: Accuracy = (TP + TN) / (TP + FP + TN + FN);
179   Sensitivity = TP / (TP + FN); Specificity = TN / (TN + FP); FDR = FP / (TP + FP),
180   where TP true positives, TN true negatives, FP false positives, FN false negatives, and

181   FDR false discovery rate. The confidence intervals (CIs) were calculated by the method
182   of Wilson (Wilson, 1927).
183
184
185   **RESULTS**
186
187   **Assay Development**
188   The Counsyl Inherited Cancer Screen we have developed employs next-generation
189   sequencing and includes comprehensive analysis of all coding exons of *BRCA1* and
190   *BRCA2*, 20 bp of flanking intronic sequences, and selected intronic and untranslated
191   regions with known pathogenic variants (Supplemental Table 2). The test was designed
192   and optimized to detect single-nucleotide variants, indels, and copy-number variants. A
193   proprietary bioinformatics pipeline was developed for sequence data alignment and
194   variant detection as described above. To test the analytical sensitivity, specificity and
195   accuracy of the assay, we sequenced peripheral blood and cell line DNA from 114
196   samples with an extremely high mean read depth (more than 500X) across all samples.
197   Every targeted position was covered with a minimum of 20 reads.
198
199   **Analytical Validation**
200   To establish analytical accuracy for detecting single-nucleotide variants and indels, we
201   compared Counsyl *BRCA1/2* sequence data of 41 Coriell samples (listed in Supplemental
202   Table 1) to reference data obtained from the 1000 Genomes project and Counsyl
203   *BRCA1/2* sequence data for NA12878 to high-quality reference data published by
204   Illumina, Inc. (http://www.illumina.com/platinumgenomes/) (Table 2). The results
205   presented in Table 3 demonstrate that 536 true positive calls, 12,920 true negative calls
206   and no false positive or false negative calls were observed. In addition, to confirm the
207   detection of documented variants in *BRCA1/BRCA2*, 15 samples from the
208   BIC *BRCA1/BRCA2* Mutation Panel (available from Coriell) were included in the
209   validation (Table 2 and Supplemental Tables 1 and 4). The concordance between the
210   *BRCA1/2* mutations detected by the Counsyl ICS and the BIC reference data was 100%.
211
212   Furthermore, to demonstrate the accurate detection of variants that are technically
213   challenging for NGS, 10 pathogenic indels discovered in patient blood samples were
214   subjected to orthogonal confirmation by Sanger sequencing (Tables 2 and 4;
215   Supplemental Table 4). All the indels detected by the Counsyl Inherited Cancer Screen
216   were concordant with the Sanger results.
217
218   To establish analytical accuracy for detecting CNVs, we compared Counsyl copy number
219   calls to CNV calls provided by reference labs, when available, and MLPA assays
220   otherwise, on 63 samples: 13 samples from reference labs; 15 samples from the
221   BIC *BRCA1/BRCA2* Mutation Panel; 25 random blood samples; 9 patient samples
222   positive for CNVs; and NA12878 (Table 2). As shown in Table 5, 79 true positive calls,
223   3,067 true negative calls and no false positive or false negative calls were observed from
224   the analysis of 63 analyzed samples (Table 5). Among the 63 tested samples, 10 had a
225   deletion or duplication of a single exon, which can be technically challenging for NGS-
226   based analysis.

227
228 The accuracy, sensitivity and specificity are therefore all 100% for SNPs, indels, and
229 copy number variants. Only samples with reference data for the entire region of interest
230 were used to calculate these metrics in order to avoid overestimating sensitivity or its
231 confidence interval (MacAdam, 2000). We also calculated false discovery rate (FDR) and
232 the associated confidence interval (Tables 3 and 5). For SNPs and indels, the FDR is 0 of
233 536 positives, or 0% (95% CI, 0-0.7%). For CNVs, the FDR is 0 of 79 (0%, CI 0-4.6%).
234
235 Our validation samples represent a diversity of variant subtypes (Table 4 and
236 Supplemental Table 4), including 28 samples with variants technically challenging to
237 detect by NGS, such as large indels and CNVs.
238
239 **Inter-run and Intra-run Reproducibility**
240 In addition to establishing the test analytical sensitivity, specificity and accuracy, the
241 Counsyl *BRCA1/2* test was validated for intra- and inter-run reproducibility. For indel
242 detection reproducibility, each BIC sample (n=15) was run 3 times each on three flow
243 cells, for a total of 9 replicates (Supplemental Table 5). For SNV detection
244 reproducibility, 11 deidentified blood samples were rerun on 2-3 different flow cells
245 (Supplemental Table 5). For CNV detection reproducibility, 15 Coriell cell line DNA and
246 11 patient samples were analyzed in replicates (Supplemental Table 5). Concordance
247 between replicates was 100% (Supplemental Table 5), with no differences between inter-
248 and intra-run replicates observed.
249
250 **Test Compatibility with Different Input Materials**
251 Finally, to demonstrate compatibility with different sample types, deidentified paired
252 blood and saliva samples (7 pairs) were tested. The results from paired blood and saliva
253 samples were 100% concordant (Supplemental Table 5).
254
255
256 **DISCUSSION**
257
258 Pathogenic mutations in the *BRCA1/2* genes are known to be associated with increased
259 risk for breast, ovarian and other cancers. For women, the risk of developing breast
260 cancer by age 70 is approximately 60-70% for *BRCA1* and 45–55% for *BRCA2* mutation
261 carriers. The cumulative ovarian cancer risk by age 70 (including fallopian tube and
262 primary peritoneal carcinomas) is 40% for *BRCA1* and 20% for *BRCA2* mutation carriers
263 respectively (Antoniou et al., 2003; Chen & Parmigiani, 2007; King, Marks, & Mandell,
264 2003). Increasing evidence indicates that early identification of BRCA carriers is
265 important so that they can take advantage of genetic counseling, screening, and
266 potentially life-saving prevention strategies.
267
268 NGS is increasingly being applied in the field of diagnostics, including *BRCA* analysis.
269 An optimized and validated assay design is critical to maximizing the analytical
270 performance of NGS assays and ensuring high-quality interpretation to facilitate clinical-
271 decision making. Here, we describe the design and analytic validation of the Counsyl
272 Inherited Cancer Screen, a next-generation-sequencing-based test to detect pathogenic

273 variation in the *BRCA1/2* genes. We demonstrate that the test is capable of detecting
274 SNVs, indels, and copy-number variants with zero errors over a 114-sample validation
275 set consisting of samples from cell lines and deidentified patient samples. Among the 114
276 tested samples, 28 (25%) were samples with challenging variants, including single- and
277 multi-exon deletions/duplications (n=22) and >10bp indels (n=6). The high sensitivity
278 and specificity achieved in our study are comparable to the results of similar studies
279 (Bosdet et al., 2013; Judkins et al., 2015; Lincoln et al., 2015; Strom et al., 2015),
280 although some NGS studies report a higher false positive rate (Chong et al., 2014).
281
282 Some laboratories confirm NGS findings to reduce the risk of false positives (Chong et
283 al., 2015; Lincoln et al., 2015). Result confirmation is recommended when the analytic
284 false positive rate is high or not yet well established (Rehm et al., 2013). Confirmation
285 can also be used to verify sample identity, which is critical when laboratory workflows
286 are complex and not fully automated (Rehm et al., 2013). However, more recent work
287 indicates that variant calls by NGS may be more reliable than relying on Sanger
288 confirmation (Beck et al., 2016). In this study, we have orthogonally confirmed a number
289 of SNV and CNV calls (using Sanger or MLPA testing, respectively: Table 2), and
290 observed neither false positive nor false negative calls for sample with reference data
291 across the entire region of interest. Additionally, the laboratory workflow described is
292 fully automated, with positive sample tracking throughout the entire process. Barcode
293 scans are performed of each tube and plate at all handling and pipetting steps. All sample
294 processing actions performed by automated instruments are logged, and video of the
295 decks of liquid handling instruments is continuously recorded.
296
297 In conclusion, we describe the development and analytical validation of a cost-effective,
298 high-throughput NGS assay for the detection of *BRCA1* and *BRCA2* pathogenic
299 mutations suitable for the clinical laboratory. We confirm that our test meets the rigorous
300 quality standards necessary for clinical implementation (Rehm et al., 2013). The test is
301 offered by Counsyl's laboratory, which is CLIA certified (05D1102604), CAP accredited
302 (7519776), and NYS permitted (8535).

571 **Tables**
572
573
574 **Table 1.** *BRCA1* and *BRCA2* cancer risk management options and effectiveness
575
576

Risk Management Options	Effectiveness
Prophylactic mastectomy	Up to 90% reduction in breast cancer risk (Hartmann et al., 1999; Hartmann et al., 2001; Meijers-Heijboer et al., 2001)
Prophylactic oophorectomy	~50% reduction in breast cancer risk when performed premenopausally (more pronounced effect for *BRCA2* mutation carriers compared to *BRCA1*) (Kauff et al., 2002; Kauff et al., 2008) Up to 96% reduction in ovarian cancer risk (Olopade & Artioli, 2004; Rebbeck et al., 2002; Rutter et al., 2003)
Tamoxifen	Up to 62% reduction in breast cancer risk among *BRCA2* mutation carriers Up to 50% contralateral breast cancer risk reduction in both *BRCA1* and *BRCA2* Limited data but appears to be more effective in *BRCA2* mutation carriers compared to *BRCA1* (King et al., 2001; Metcalfe et al., 2005; Narod et al., 2000)
Oral contraceptives	Up to 50% reduction in ovarian cancer risk (Iodice et al., 2010)
Breast MRI/mammogram	No risk reduction, but earlier detection (Kuhl et al., 2010; Sardanelli et al., 2011; Warner et al., 2011)
Ovarian cancer screening (transvaginal ultrasound and serum cancer antigen 125 (CA-125))	No risk reduction and no effect on cancer mortality (Buys et al., 2011; Clarke-Pearson, 2009)

577
578
579

580
581 **Table 2.** Source of samples and reference data used in validation
582
583

Mutation Type	Test Samples	Reference Data
SNV/Indel	41 Coriell Cell Line Samples	1000 Genomes Project Exomes
	NA12878	Illumina Platinum Genome
	15 BIC samples	BIC reference data
	10 positive patient samples	Orthogonal confirmation by Sanger
CNV	NA12878	Orthogonal confirmation by MLPA
	15 BIC samples	Orthogonal confirmation by MLPA
	13 reference lab samples	Reference lab results
	25 random patient samples	Orthogonal confirmation by MLPA
	9 positive patient samples	Orthogonal confirmation by MLPA

584
585
586
587

588
589   **Table 3.** Performance of Counsyl Inherited Cancer Screen for SNPs and indels
590
591

Counsyl ICS	1000 Genomes reference data		Results (95% confidence interval)
	Variant present	Variant not present	
Variant detected	536 true positives	0 false positives	100% accuracy (0.999-1.0) 100% sensitivity (0.993-1.0) 100% specificity (0.999-1.0) 0% FDR (0-0.7%)
Variant not detected	0 false negatives	12,920 true negatives	

592
593   Only samples with reference data for the entire region of interest were used to calculate the
594   analytic concordance. Validation metrics were defined as: Accuracy = (TP + TN) /(TP + FP + TN
595   + FN); Sensitivity = TP / (TP + FN); Specificity = TN / (TN + FP); FDR = FP / (TP + FP). For
596   true negative and true positive calculations, all polymorphic positions (positions at which we
597   observed non-reference bases in any sample) across all samples were considered.
598
599

600
601   **Table 4.** Positive Variants Included In Validation Study
602
603

Mutation Type	Subtype	Number of Positive Variants	
		Reference Data	Orthogonal Confirmation
SNV	N/A	525	
Indel	Indels < 10 bp	10	4
	Indels >= 10 bp	1	6
CNV	Single-exon deletions or duplications		10
	Multiple exon deletions or duplications		69

604
605
606
607

608
609 **Table 5.** Performance of Counsyl Inherited Cancer Screen for Copy Number Variants
610
611

Counsyl ICS	MLPA reference data		Results (95% confidence interval)
	CNV present	CNV not present	
CNV detected	79 true positives	0 false positives	100% accuracy (0.999-1.0) 100% sensitivity (0.951-1.0)
CNV not detected	0 false negatives	3067 true negatives	100% specificity (0.999-1.0) 0% FDR (0-4.6%)

612
613 Only reference data with full copy number assessment of the *BRCA1/2* genes were included.
614 Validation metrics were defined as: Accuracy = (TP + TN) /(TP + FP + TN + FN); Sensitivity =
615 TP / (TP + FN); Specificity = TN / (TN + FP); FDR = FP / (TP + FP). True positives and true
616 negatives were computed on a per-exon basis.
