How to review

When ready **submit your review online**. The review form is divided into 5 sections. Please consider these when composing your review:

- **1. BASIC REPORTING**
- 2. EXPERIMENTAL DESIGN
- **3. VALIDITY OF THE FINDINGS**
- 4. General comments
- 5. Confidential notes to the editor
- You can also annotate this **pdf** and upload it as part of your review

To finish, enter your editorial recommendation (accept, revise or reject) and submit.

BASIC REPORTING

Clear, unambiguous, professional English language used throughout.
 Intro & background to show context. Literature well referenced & relevant.
 Structure conforms to Peerl standard, discipline norm, or improved for clarity.
 Figures are relevant, high quality, well labelled & described.
 Raw data supplied (See Peerl policy).

VALIDITY OF THE FINDINGS

- Impact and novelty not assessed. Negative/inconclusive results accepted. *Meaningful* replication encouraged where rationale & benefit to literature is clearly stated.
 - Data is robust, statistically sound, & controlled.

EXPERIMENTAL DESIGN

 sh
 Original primary research within Scope of the journal.

 Image: Short Scope of the journal.
 Research question well defined, relevant & meaningful. It is stated how research fills an identified knowledge gap.

 Image: Short Scope of the journal.
 Rigorous investigation performed to a high technical & ethical standard.

 Image: Short Scope of the journal.
 Rigorous investigation performed to a high technical & ethical standard.

 Image: Short Scope of the journal research question to replicate.
 Methods described with sufficient detail & information to replicate.

 Image: Short Scope of the journal research question & limited to supporting results.
 Speculation is welcome, but should be identified as such.

The above is the editorial criteria summary. To view in full visit <u>https://peerj.com/about/editorial-</u> criteria/

Morphometric comparisons of plant-mimetic juvenile fish associated with plant debris observed in the coastal subtropical waters around Kuchierabu-jima Island, southern Japan

Alexya Cunha de Queiroz, Yoichi Sakai, Marcelo Vallinoto, Breno Barros

The general morphological shape of plant-resembling fish and plant parts were compared using a geometric morphometrics approach. Three plant-mimetic fish species, *Lobotes surinamensis* (Lobotidae), *Platax orbicularis* (Ephippidae) and *Canthidermis maculata* (Balistidae), were compared during their early developmental stages with accompanying plant debris (i.e. leaves of several taxa) in the coastal subtropical waters around Kuchierabu-jima Island, closely facing the Kuroshio Current. The degree of similarity shared between the plant parts and co-occurring fish species was quantified, however fish remained morphologically distinct from their plant models. Such similarities were corroborated by analysis of covariance and linear discriminant analysis, in which relative body areas of fish were strongly related to plant models. Our results strengthen the paradigm that morphological clues can lead to ecological evidence to allow predictions of behavioural and habitat choice by mimetic fish, according to the degree of similarity shared with their respective models. The resemblance to plant parts detected in the three fish species may provide fitness advantages via convergent evolutionary effects.

22 Abstract

23 The general morphological shape of plant-resembling fish and plant parts were compared using a 24 geometric morphometrics approach. Three plant-mimetic fish species, Lobotes surinamensis 25 (Lobotidae), Platax orbicularis (Ephippidae) and Canthidermis maculata (Balistidae), were 26 compared during their early developmental stages with accompanying plant debris (i.e. leaves of 27 several taxa) in the coastal subtropical waters around Kuchierabu-jima Island, closely facing the 28 Kuroshio Current. The degree of similarity shared between the plant parts and co-occurring fish 29 species was quantified, where fish and plants presented highly similar morphometric associations, 30 yet remaining morphologically distinct. Such similarities were corroborated by analysis of 31 covariance and linear discriminant analysis, in which relative body areas of fish were strongly 32 related to plant models. Our results strengthen the paradigm that morphological clues can lead to 33 ecological evidence to allow predictions of behavioural and habitat choice by mimetic fish, 34 according to the degree of similarity shared with their respective models. The resemblance to 35 plant parts detected in the three fish species may provide fitness advantages via convergent 36 evolutionary effects.

42 1. Introduction

43

44	Mimesis is defined as a phenotype evolved in response to selective pressures favouring
45	individuals that can disguise their identity by masquerading as another organism (Pasteur, 1982;
46	Skelhorn, Rowland & Ruxton, 2010a; Skelhorn et al., 2010b). Mimesis in fish is a relatively
47	well-studied subject (Wickler, 1968; Moland, Eagle & Jones, 2005; Robertson, 2013),
48	particularly regarding deceptive resemblance to plant parts via protective camouflage, which is a
49	known feature in several freshwater and marine fish species, as extreme crypsis examples of
50	protective resemblance (Breder, 1946; Randall, 1965, 2005a; Vane-Wright, 1980; Sazima et al.,
51	2006). Although these reports have addressed the patterns and general similarities in morphology
52	or colouration of model plant parts and mimetic fish, few studies have examined similarities
53	among them based on morphological and/or ethological details (Barros et al. 2008, 2011, 2012).
54	Studies focusing on morphology and geometric morphometrics frequently used fish species
55	as models, and several authors have suggested that morphological clues can be used as
56	ecological predictors from basic behavioural constraints, such as swimming mode (Walker,
57	2004; Comabella, Hurtado & García-Galano, 2010; Xiong & Lauder, 2014), feeding behaviour
58	(Galis, 1990; Franssen, Goodchild & Shepard, 2015) and habitat choice (Loy et al., 1998;
59	Gibran, 2010; Soares, Ruffeil & Montag, 2013), especially in juvenile fish, suggesting that such
60	changes are important for improving fitness and increasing the chance for survival during
61	subsequent ontogenetic stages (Barros et al., 2011; Comabella et al., 2013). Nevertheless, such a
62	tool has not been used to establish comparisons among distant taxa belonging to completely
63	different groups (i.e. fish and plants). In the present study, previously well-known plant-mimetic
64	juvenile fish, the tripletail, Lobotes surinamensis (Bloch, 1790), the orbicular batfish, Platax

orbicularis (Forsskål, 1775) and the ocean triggerfish, *Canthidermis maculata* (Bloch, 1786)
were compared with their respective plant models co-occurring in the field to objectively
evaluate their resemblance in shape to their respective models. All fish and plant models were
observed and sampled from Kuchierabu-jima Island and its surrounding waters, which suffers a
strong influence of Kuroshio Current.

70 Lobotes surinamensis is generally found in shallow brackish water habitats but may occur 71 far offshore with drifting algae or flotsam, and juveniles may lie on their side matching the 72 colour of the plant debris, from near black to yellow (Randall, 2005b). Juveniles are usually 73 dark-coloured, presenting drifting swimming patterns among dry leaves, exhibiting similar 74 movements to their associated plant model (Uchida, 1951; Randall, 2005b). Uchida (1951) also 75 described that young C. maculata resemble pieces of pine bark and were observed drifting 76 among pieces of bark in a horizontal swimming posture, suggesting mimetic effects. Juveniles of P. orbicularis look similar to yellow waterlogged jack tree leaves (genus Rhizophora) and 77 78 greatly resemble floating dead leaves (Wiley, 1904; Breder, 1946). Randall (1960) reported that 79 larger individuals (87 mm standard length [SL]) resemble large sea hibiscus leaves (Hibiscus 80 *tiliaceus*) with a yellowish-brown colouration, with dorsal and anal fins appearing to lengthen 81 with growth. Such drastic changes in morphological shape occur in juvenile *P. orbicularis* while 82 they maintain a resemblance to drifting leaves (Barros et al., 2015).

The novel comparative methods presented herein may provide useful associations between behavioural ecology and morphological studies. We tested the null hypothesis of a lack of shape similarity among the studied fish and plant parts, considering both classic and geometric morphometrics comparative approaches. We briefly discuss the functional contributions of camouflage characteristics to fish fitness using mimetic shape attributes as a disguise based on

morphological resemblance data among fish and model plants, adopting the concepts of cryptic
mimesis as synonym of protective camouflage or masquerading, following the definitions as
proposed by Pasteur (1982), where all fish samples are defined as "mimetic fish" and all plant
part samples as "models", instead of adopting the terminology as proposed by Skelhorn,
Rowland & Ruxton (2010a). This is due to the highly dynamic environments such fish usually
occur, where mimetic behaviour is achieved not only by appearance, but also through actively
behaving alike the drifting models (Barros *et al.*, 2008).

95

96 2. Material and Methods

97

98 2.1. Sampling

99 Sampling was mainly conducted in the port of Honmura, Kuchierabu-jima Island (Ohsumi 100 Group, 30° 28' N, 130° 10' E), southern Japan, during diurnal observations July 3–14, 2011 (S1 101 Fig.). The island closely faces the Kuroshio Current and maintains a rich subtropical fish fauna 102 (Gushima & Murakami, 1976). Fish samples and plant debris were collected using hand nets, and the sampled fish were euthanized using 5 ml 95 % eugenol in 1 L ethanol as a stock solution 103 104 All fish samples were preserved in order to maintain integrity of peripheral structures and 105 general shape, and were photographed as soon as possible, in order to avoid any arching or 106 deformation effect from the fixation protocols established (Valentin et al., 2008). All plant 107 materials were sampled at the island along with their associated fish. Of this, 20 ml was added to 108 each 1 L of water containing the fish to be euthanized to minimise suffering, following 109 international ethical standards (Jenkins et al., 2014). As there is no national Japanese licensing 110 framework, samples were collected following the "Guidelines for Proper Conduct of Animal

Manuscript to be reviewed

111 Experiments" set out by the Hiroshima University Animal Research Committee, which are based 112 on international ethical standards, and only after obtaining local community permission. 113 Fish samples from Kuchireabu-jima Island were identified to as low a taxonomic category 114 as possible, according to available literature (Nakabo, 2002; Nelson, 2006; Okiyama, 2014). 115 Fifteen mimetic fish specimens of three species (Fig. 1A-C) were observed to drift around plant 116 debris: Lobotes surinamensis (Lobotidae; n = 6, TL = 3.89 ± 0.46 cm; AVE \pm SDEV values), 117 *Platax orbicularis* (Ephippidae; n = 7 TL = 2.05 ± 0.42 cm) and *Canthidermis maculata* (Balistidae; n = 2, TL = 3.15 ± 0.98 cm). Additional 24 fish specimens (n = 14 for L. 118 119 surinamensis, n = 10 for C. maculata) sampled in subtropical waters of Kagoshima prefecture 120 were also obtained from the collections of the Kagoshima University Museum (KAUM) to 121 enhance and equalize sample size of our data set for the statistical analyses (see below). The 122 KAUM samples were all juveniles, with relatively similar standard length as those observed (L. 123 surinamensis TL = 4.92 ± 2.02 cm, and C. maculata TL = 3.95 ± 0.98 cm) and collected near to 124 the present study area, i.e., Satsuma Peninsula of mainland Kagoshima, Tanega-shima Island, 125 and Yaku-shima Island (31°28'-31°33'N, 130°11'-130°51'E) (for details refer to S2 Dataset). Of these, the most images were provided by the KAUM (N = 5 for C. maculata and N = 11 for L. 126 127 surinamensis), taken from fresh specimens. All other samples were photographed in the 128 Laboratory of Biology of Aquatic Resources, at the Hiroshima University, and only those with 129 all peripheric structures intact were considered in the analysis. No arched or deformed specimens 130 were used during the analyses, in order to prevent from any misinterpretation of data. Also, 131 additional twelve samples of P. orbicularis (TL = 2.05 ± 0.91 cm) collected during previous surveys on Kuchierabu-jima Island (Barros et al. 2008, 2011) were eventually employed, in order 132 133 to equalize N size. Total 52 individual mimetic fishes were analysed.

134 Floating plant debris (hereafter, models, n = 43) were collected using hand nets and sorted, 135 then visually subdivided using two subjective criteria (round shapes, as for the Podocarpaceae 136 *Nageia nagi* and the Sapindaceae *Acer morifolium*; or elongated shapes, as for the Laureaceae 137 Neolitsea sericea and for the Fagaceae Castanopsis sieboldii; Fig. 1D-E), regardless of 138 taxonomy and dried in paper envelopes until they were photographed for further analysis. 139 High resolution digital pictures of the left lateral view of the mimetic fish and model 140 samples were taken over a black background using a Nikon D700 equipped with AF-S 60-mm 141 immersive lens and a stand table with a reference scale of 1 cm for the fish and models. The left 142 lateral view of the models was defined as the "dorsal view of leaves with the petiole oriented to 143 the right". Artificial light was used to avoid shading morphological structures. 144 145 2.2. Data Analyses 146 Sixteen landmarks (LM) were established for the mimetic fish and models using ImageJ v. 1.47 software for geometric morphometrics purposes (Abramoff, Magelhaes & Ram, 2004). 147 148 Homologous LM for the mimetic fish were marked obeying the morphological structures 149 constrained or related to mimetic behaviour to cover the fish general outline profile, including 150 peripheral structures (Fig. 1A, Table I). We established equidistant 16 semilandmarks (SLM) for 151 each model using the ImageJ grid tool to cover all lateral profiles of the model, obeying the same 152 marking distribution as for the mimetic fishes (Fig. 1D). Raw coordinates LM and SLM data 153 were implemented in MorphoJ v. 1.02n software (Klingenberg, 2011), where preliminary 154 adjustments, such as the Procrustes fit, and creation of the data matrix, were done. The 155 morphometric comparisons among the fish and models were not intended to analyse homologous

156 patterns, as we were interested in shape similarities randomly shared among the mimetic fish and

Manuscript to be reviewed

their respective models distributed in the same environment, from a geometric morphometrics
perspective. Therefore, the necessity of marking peripheral anatomic structures in the mimetic
fish, instead of fins insertions only, in order to check for general appearance of mimetic fish with
the plant models.

Data analyses were performed with Geomorph v. 2.0 software (Adams & Otarola-Castillo, 2013). A post-hoc general Procrustes analysis (GPA) and principal components analysis (PCA) were run followed by analysis of variance (ANOVA) to compare the mimetic fish and models plotted together in the analyses. Also, a linear discriminant function was run, in order to visualize how close were these group associations, using the package MASS v. 7.3-42 (Venables &

166 Ripley, 2002).

167 In addition, individual TL and relative body area (BA, cm²/TL) of the fish and models

168 were calculated using ImageJ to establish interdependent comparisons among the fish species

and plant debris via analysis of covariance (ANCOVA), followed by a linear discriminant

analysis (LDA), to accurately predict whether the mimetic fish can be misclassified as a model.

171 BA was chosen because of its importance for discriminating teleost aggregations (Gómez-

172 Laplaza & Gerlai, 2013). Fish were measured from the tip of the snout to the edge of the caudal

173 fin (TL), and models were measured from edge to edge and considered TL. All statistical

analyses were conducted in 'R' v. 3.1.3 (R Development Core Team, 2015), and all relevant data

175 for the current analysis are available within this paper (S2 dataset).

176

177 **3. Results**

178

179	Mimetic fish were observed mimicking plant debris near the water surface in all extensions of
180	the port of Honmura. The mimetic assemblages resembled the models in shape, colour and
181	drifting movements, having shared the same environment during the entire sampling period. All
182	fish drifted among fallen plant debris near the water surface.
183	The visual GPA analysis indicated a significant variance in the shape configurations
184	among the different models (Fig. 2A) and mimetic fish (Fig. 2B). All-pooled data showed a
185	relative tendency of the mimetic fish to resemble plant debris with $\sim 24\%$ of the variation
186	explained in PC1 and ~10% of the variation explained in PC2 (ANOVA $F_{2,52}$ = 40.97, $P < 0.001$,
187	Fig. 2C), yet remaining morphologically distinct, as observed in the GPA analyses.
188	BA of the mimetic fish and models regressed against TL revealed a significant
189	interdependency (ANCOVA, $F_{2,96}$ = 92.06, $P < 0.001$; Fig. 3), where juvenile <i>L. surinamensis</i> , <i>P</i> .
190	orbicularis and C. maculata have shown a size gradient, sharing similar BA with round and
191	elongated leaves of different sizes, accordingly to different growth stages of each mimetic fish
192	species, with some deviation observed for the round leaf models. These results were
193	corroborated by LDA, which has shown high similarities in shape of mimetic fish and models,
194	with a 52.52% probability of misclassification among the observed individuals. Details on both
195	ANCOVA and LDA can be found at S2 dataset.
196	
197	4. Discussion

198

The present results show shape heterogeneity among mimetic fish and plant models, with asignificant level of similarity shared in their general external shape profile. Such results are

201 highly expected, as mimetic behaviour is more likely to be driven by a combination of factors

202 (i.e.: shape, colour and movements) than solely by morphological attributes (Wickler, 1968; 203 Pasteur, 1982). Although the importance of floating plant debris for passive transportation, 204 providing shelter and feeding grounds for fish in coastal environments has been evaluated 205 (Castro, Santiago & Santana-Ortega, 2001; Vandendriessche et al., 2007), the closeness of these 206 interactions has not been investigated, particularly regarding plant resemblance by fish. 207 Arching effects due to fixation protocols are known to strongly influence geometric 208 morphometric analyses (Valentin et al., 2008). Although we have combined data from museum 209 specimens with our own samples, we have selected only intact individuals for the present 210 analyses. According to observed shape similarities shared among the mimetic fish and models, it 211 was clear that the present fish assemblage accompanied their respective models, being probably 212 dependent on drifting plant material for survival, also suggested by the linear model of 213 covariance shared amongst drifting fish and plants. While not the primary goal of the present 214 study, such association might suggest an allometric dependence for the plant mimetic species, at 215 least until a given ontogenetic stage when such fish species suffer significant changes in 216 morphology and behaviour, cessing with the mimetic association with plants (Barros *et al.*, 217 2015). 218 The concepts regarding mimetic behaviour are still a matter of discussion, as it is difficult 219 to define a case of mimetic association using only a shape resemblance to another 220 animal/inanimate object (Skelhorn, Rowland & Ruxton, 2010a; Skelhorn et al., 2010b), 221 especially in marine systems (Robertson, 2013; 2015). The observed species herein not only 222 presented good shape similarity with the models, but also behaved alike, via drifting movements along with their respective models, far away from being "inanimate" (BBarros, personal 223 224 observation; S3 video). Close resemblance of fish to their models in shape and drifting behaviour

Manuscript to be reviewed

at the water surface environment could confuse visually oriented predators through the
camouflage effect. Thus, "mimetic behaviour" was a valid classification in the present case.
All species tested in the present study, such as *L. surinamensis* (Lobotidae), *C. maculata*(Balistidae) and *P. orbicularis* (Ephippidae) have been described previously as resembling dried

leaves in shallow water (Uchida, 1951; Breder, 1942, 1946, 1949; Randall & Randall, 1955;
Barros *et al.*, 2008, 2011, 2012), and are commonly found in the surveyed area (Motomura *et al.*,
2010).

232 Although coastal fish resembling a plant via cryptic colouration has been an intriguing 233 subject since the early reports, the present study is the first attempt to establish analytical 234 comparisons between mimetic fish and models at the morphometrics level. Kelley & Merilaita 235 (2015) suggested that successful crypsis in fish is more likely achieved through colouration, via a 236 background matching effect. Although we did not test the predation rate of mimetic fish nor for 237 any colour influence, our results add relevant information, in which background matching is achieved not only by cryptic colouration (Breder, 1946; Randall & Randall, 1960; Randall, 238 239 2005b), but also through shape and behavioural resemblance of mimetic fish to their respective 240 models. The present level of protective camouflage shared by the fish assemblage analysed 241 herein might be important against potential aerial and bottom predators, as background colour 242 matches surrounding environments (Donnely & Whoriskey Jr., 1991; Cortesi et al., 2015; Kelley & Merilaita, 2015). However, no predatory attempt by a bird species has been observed. Further 243 244 experiments and field observations of all observed species are necessary to test this assumption. 245 The co-occurring mimetic assemblages observed herein are a typical example of 246 convergent evolution in a coastal environment (Endler, 1981; Hamner, 1995; Johnsen, 2014).

247 Some taxa analysed undergo numerous morphological and ethological changes. For example, *P*.

248 orbicularis adults inhabit deeper environments, changing in both shape and behaviour within the 249 settlement (Kuiter & Debelius, 2001; Barros et al., 2011). As major morphological changes are 250 usually expected through ontogeny of several fish groups (Galis, 1990; Loy et al., 1998; 251 Comabella, Hurtado & García-Galano, 2010; Leis et al. 2013; Nikolioudakis, Koumoundouros & 252 Somarakis, 2014; Barros *et al.*, 2015), resemblance to leaves by the fish species observed here 253 may be crucial for first settlement, as it could improve survival chances (Johnsen, 2014). 254 The Kuroshio-Current is regarded as a key factor for passive transportation of masses of 255 plant and algae material and juvenile fishes closely associated with, as such ichthyofauna use the 256 plant debris as both shelter and food source (Kimura et al., 1998). Strictly morphological studies 257 are ineffective for providing all of the clues necessary to interpret the natural history of most 258 living organisms (Scholtz, 2010). The present observations support fundamental information on 259 the distributions of these fish species during early stages, their life history and evolutionary paths 260 if combined with mimetic fish and model ethological and ecological data that are available for 261 some taxa (Barros et al., 2008, 2011, 2012). Although refinements to the methodologies are 262 necessary, this new comparative approach may stimulate discussion of morphology as a 263 predictor of ecology (Douglas & Matthews, 1992; Gibran, 2010; Oliveira et al., 2010). 264

265 Acknowledgements

266 We thank all members of the Kuchierabu-jima Island community, particularly M. Yamaguchi,

the crew of the Laboratório Multi-Imagem and F. R. R. de Oliveira (UFPA), and A. Akama

Table 1(on next page)

List of landmarks

List of homologous landmarks and criteria adopted for selecting each landmark used for the mimetic fish

1

Manuscript to be reviewed

Landmark	Landmark description
1	Tip of the snout
2	Nasal cavity
3	Posterior limit of supra-occipital
4	Anterior insertion of dorsal fin
5	Edge of last hard spine
6	Insertion of soft rays
7	Maximum height of dorsal fin
8	Posterior insertion of dorsal fin
9	Upper limit of caudal fin
10	Hypural joint
11	Lower limit of caudal fin
12	Posterior insertion of anal fin
13	Maximum height of anal fin
14	Anterior insertion of anal fin
15	Insertion of pelvic fin
16	Lower occipital edge

1

Mimetic fish and plant models

Morphometric comparisons of plant-mimetic juvenile fish associated with plant debris observed on Kuchierabu-jima Island, southern Japan Examples of mimetic fish and their models (i.e. floating plant debris) occurring in the shallow waters of Honmura Port, Kuchierabu-jima Island, southern Japan. a) *Lobotes surinamensis*, b) *Canthidermis maculata* and c) *Platax orbicularis* are the mimetic fish observed. The models were subdivided using three criteria of: d) round leaves, and e) elongated leaves. The established landmarks and semilandmarks are denoted in (a) for the mimetic fish and in (f) for the models, respectively. White bars indicate 1 cm.

*Note: Auto Gamma Correction was used for the image. This only affects the reviewing manuscript. See original source image if needed for review.

Manuscript to be reviewed

Figure 2(on next page)

Morphometric relationships among mimetic fish and plant models

Morphometric comparisons of plant-mimetic juvenile fish associated with plant debris observed on Kuchierabu-jima Island, southern Japan Diversity of shapes observed for the models (i.e. floating plant debris) (a) and fish mimics (b), via a general Procrustes analysis (GPA); and principal components analysis (PCA; c), of all- pooled data indicating a high tendency for shape similarities shared by the mimetic fish and models (i.e. floating plant debris), where green plots represent leaf models (dark green representing rounded leaf models and lighter green representing elongated leaf models). Mimetic fish are represented by *Lobotes surinamensis* (yellow), *Platax orbicularis* (red), and *Canthidermis maculata* (white).

Manuscript to be reviewed

3

ANCOVA

Morphometric comparisons of plant-mimetic juvenile fish associated with plant debris observed on Kuchierabu-jima Island, southern Japan Similar relative body area values were observed among the models (i.e. floating plant debris) and mimetic fish, where mimetic fish are represented by *Lobotes surinamensis* (yellow), *Canthidermis maculata* (white) and *Platax orbicularis* (red), and plant models are represented by green plots (dark green representing rounded leaf models and lighter green representing elongated leaf models).
