Abstract:

Problem: The purpose of this work is to provide some validation methods for evaluating the hemodynamic assessment of Cerebral Arteriovenous Malformation (CAVM). This paper emphasizes the importance of validating noninvasive measurements for CAVM patients, which is designed using lumped models for complex vessel structure.

Methods: The validation of hemodynamics assessment is based on invasive clinical measurements and cross-validation techniques with Philips propriety validated software's Qflow and 2D-Perfusion.

Results: The modeling results are validated for 30 CAVM patients for 150 vessel locations. Mean flow, diameter, and pressure were compared between modeling results and with clinical/cross validation measurements, using independent 2-tailed Student t test. Exponential regression analysis was used to assess the relationship between blood flow, vessel diameter, and pressure between them. Univariate analysis is used to assess the relationship between vessel diameter, vessel cross-sectional area, AVM volume, AVM pressure, and AVM flow results was performed with linear or exponential regression. The AVM modeling results are compared with Philips propriety software Qflow. The modelling results is matching nearly with 90% accuracy with Qflow results. The 2D perfusion modeling results matches nearly 88% accuracy with 2D Perfusion software.

Discussion: Modeling results were compared with clinical measurements from vessel locations of cerebral regions. Secondly, model is cross validated with Philips propriety validated software's Qflow and 2D-Perfusion. Our results shows modeling results and clinical results are nearly matching with a deviation of 10-12%

Conclusion: In this paper, we have validated our modeling results with clinical measurements. The new approach for cross-validation is proposed, by validating our results with validated product in clinical environment.

Keywords: Arteriovenous Malformation, Simulation, Hemodynamics, Cross-Validation.

1.0 Introduction:

CAVM is one of the neurovascular malformations. The cerebral vasculature of healthy normal's consists of arteries and veins which are connected by capillaries. In CAVM - capillaries are absent resulting in tangled cluster of vessels. The vessel geometry in CAVM is complex in nature. The CAVM patient is affected by hemodynamics changes. Invasive techniques are the current clinical procedure to measure hemodynamics of CAVM. The invasive technique is riskier to patients as CAVM get rupture. Figure 1 shows complex structure of CAVM. The gold standard imaging for CAVM is Digital Subtraction Angiogram (DSA), figure 2 shows the CAVM – DSA image [Liu 1993; Omar Saleh 2008; Yasargil MG 1987].

In this paper, we have validated our modeling results with clinical measurements and with cross –validation techniques. We replicate actual patient condition, by simulating similar condition of patient using Matlab simulation. Lumped models are created and simulated using different signal combinations. This helps to validate our results with clinical measurements.

Figure 1- Cerebral Arteriovenous Malformation (CAVM).

Figure 2- Digital Subtraction Angiogram of CAVM Image.

2.0 Methodology:

The non-invasive technique to measure hemodynamics in the complex vessel in CAVM is based on lumped model. In this paper, we focus on the different validation techniques to validate our modeling results. The non-invasive measurements are validated in two ways: Invasive technique and Cross validation. The complex vessel structures are formed by combinations such as bifurcation, vessel feedback, vessel deformation, vessel collapsing, vessel bending, tortuosity, etc. The analysis for complex vessel structure is performed using lumped modeling [Kumar, Mehta & Ramachandra, 2014; Kumar, Mehta & Ramachandra, 2013a; Kumar, Mehta & Ramachandra, 2013b]. The output pressure measurement of lumped model is validated with invasive and cross-validation techniques for 30 CAVM patients, with 150 vessel locations.

2.1 Invasive Techniques:

The clinical procedure to acquire data from patient, is to insert catheter from femoral artery by performing single and multi-puncture in the femoral artery. The catheter is of 0.08 inch /0.2 mm with 200mm length [Omar Saleh 2008]. The catheter wire is propagated slowly with various stuck-up at various bends and various structure changes of the vessels as shown in figure 3. The catheter is navigated slowly in between the path, till it reaches the CAVM vessels [Valavanis et.al, 2005]. The ethical clearance is received for this study. The KMC Manipal has approved the clearance for this study.

Figure 3 - Neurovascular Catheter Procedure

(Adapted from <http://weillcornellbrainandspine.org/condition/stroke/surgery-ischemic-stroke>)

The pressure bag has the pressure sensors that are connected externally to the guided catheter. The pressure bag readings are shown in patient monitor system. After reaching required vessel location, the clinician measure the pressure value from the patient monitor. The patient monitor also shows ECG, heart rate, respiratory rate along with pressure value. Figure 4 shows a patient monitor along with pressure values obtained from Cathlab KMC Manipal. The pressure is measured for various arteries – left external cerebral artery, internal carotid artery, posterior cerebral artery, middle

cerebral artery, near Nidus [Standring 2008]. This procedure is used to measure pressure at various vessels locations in Cathlab. The pressure values obtained by clinical procedure is taken as reference for validation of modeling results.

Figure 4- Clinical Pressure Measurements
(Courtesy: Kasturba Medical College & Hospital, Manipal)

2.2 Cross Validation:

The cross validation techniques is a type of validation, where the modeling results are cross validated with equivalent software, which produces same results. In our paper, we validated our results with Philips propriety software such as Q-Flow and 2D-Perfusion analysis software.

2.2.1 Q-Flow Software:

The validations of complex geometries, feeding arteries are performed using Philips propriety product called Qflow. Qflow is developed and validated by Philips Healthcare. Qflow is commonly used in hospitals for clinical diagnosis and treatment. This is as validated software, accepted by clinicians [Lotz J 2002; Kondo 1991]. The Qflow application requires MR Angiogram (MRA) data – Fast Field Echo (FFE) & Phase, for processing. MRA data of CAVM patient with different phase information is obtained from KMC hospital. The MR Angiogram is an imaging technique to obtain phase, flow analysis of the patient. The MRA for cerebral patients gives cerebral flow parameters. Using Qflow software, we obtain the velocity of the blood flow. The velocity is converted to pressure, which is used for our validation analysis. Our study have approximated conversion between the velocities to pressure. This approximation results in loss of accuracy, which is analyzed in Results section.

2.2.2 2D-Perfusion Software:

The modeling results are validated with Philips Propriety Cathlab software - 2D-Perfusion. The input data is DSA image. Philips validated 2D Perfusion software is a software product that provides functional information about tissues perfusion based on a digital subtraction angiography (DSA). It can visualize multiple parameters related to perfusion.

Statistical Analysis:

Mean flow, diameter, and pressure were compared between modeling results and with clinical/cross validation measurements, using independent 2-tailed Student t test. Refer Appendix

1 for t test results. Exponential regression analysis was used to assess the relationship between blood flow, vessel diameter, and pressure between them. Univariate analysis is used to assess the relationship between vessel diameter, vessel cross-sectional area, AVM volume, AVM pressure, and AVM flow results was performed with linear or exponential regression.. Two-way tables were verified using Fisher's exact test, and regular logistic regression was used to evaluate the association between pressure and diameter variation in the vessel. All analyses were performed with SPSS (Version 22; IBM Inc.)[Anna M. Fica et.al 2014].

Node voltage outputs were expressed as mean value \pm Standard deviation. A total of 30 AVM patients were studied with evaluation of 150 vessels locations as node point. The statistical analysis for various node output of loop structure is shown in table 5. -The statistical analysis shows that the average error rate less than 0.05 and mean square error is lesser compared to other simulation results. A P-value<0.05 was considered significant (refer Appendix 1 for results). The standard deviation for each node is less than 0.05, compared to other simulation results. This shows that proposed model based on non-invasive technique has advantages than other simulation techniques.

Table 5: Statistical analysis for various node output of loop structure

Quantification Parameters (for figure 5 loop structure)	Node1 Output voltage	Node2 output voltage	Node3 output voltage	Node4 output voltage	Node5 output voltage
Count	12	11	10	9	8
Minimum	3.49	3.5	3.6	3.2	3.02
Maximum	5.2	5.1	4.9	4.8	4.7
Mean	3.4159	3.4159	3.4159	3.4159	3.4159
Standard deviation (range)	0.05	0.04	0.05	0.044	0.047
Mean Squared Error	9.869587728	9.869587728	9.868770939	9.9225	9.93

3.0 Results and Discussion:

3.1 Invasive Validation:

The invasive hemodynamics measurement inside NIDUS is risky, due to complex geometric structure of NIDUS. However, with help of clinicians in Cathlab, KMC Manipal; able to measure pressure values near locations of Nidus using guided micro catheter. The various measured locations are external carotid artery, internal carotid artery, and posterior cerebral artery. The simulation is performed for the complete path node1 to node5, refer figure 5. The pressure measurements for loop structure is shown in table 1. The model is simulated with different signal magnitude variations.

Figure 5- Complex Vessel Structure

Table 1- Loop Structure Pressure Measurements and Analysis

Nodes		Input voltage Pressure = 0.8 volt / 80mmHg	
	Measured value	Clinical results	Percentage Deviation %
Node1	0.72v/72mmHg	0.74v/74mmHg	2.7
Node2	0.7v/70mmHg	0.72v/72mmHg	2.7
Node3	0.57v/57mmHg	0.60v/60mmHg	5
Node 4	0.52v/52mmHg	0.55v/55mmHg	5.4
Node5	0.47v/47mmHg	0.50v/50mmHg	6

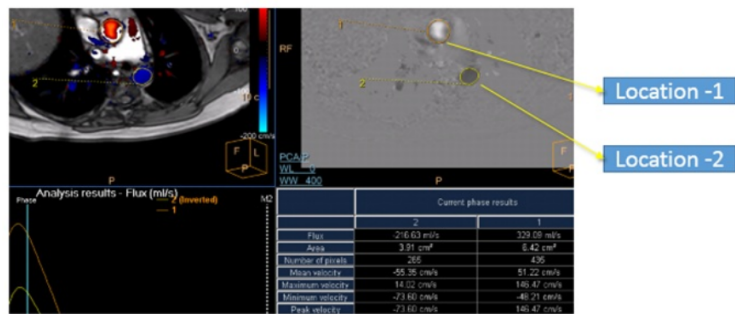

The table 1 shows modeling results are validated against clinical measurements. The input voltage/pressure used for simulation is 80mmHg/0.8 volts. Each node represents corresponding cerebral vessel location. Each node is modeled using lumped elements and the corresponding node outputs are compared against clinical measurements. The percentage deviation in table 1, represents the amount of percentage difference between the modeling results and clinical results.

3.2 Cross Validation Techniques:

3.2.1 Q-Flow Validation:

The study is validated by comparing against Qflow results with modeling results. The Qflow processing results are velocity components for specific node/region. Lumped model is created for specific node/region. The lumped model is simulated for same input used in Qflow application. Figure 6 shows MRA image of CAVM patient with velocity results for the drawn region of interest in cerebral vascular region. Table 2 compares modeling results against Qflow results along with amount of difference between them. The Qflow validation analysis is performed for each phase

168 acquisition of MRA of CAVM patient. The table shows various locations such as location 1,
169 location 2, depicts the pressure measurements at corresponding location for various phases.
170

171
172
173
174
175 Figure 6- Qflow analysis with node locations

176
177 Pre-requisite: Conversion of maximum velocity to volts

178
179 Table 2: Qflow validation with modeling results

Vessel location as per figure 6	Flow outputs Peak velocity as per Qflow outputs in volts	Electrical Network – Modeling output	Deviation %
Input	0.02Volts – input voltage (Qflow initial velocity –max 200cm/s)	0.0187Volts	6.5
Location 1	0.012 volts	0.01 volts	0.001
Location 2	0.003 volts	0.0225	0.0195

182
183 Table 3 shows pressure values obtained from each phase of MRA flow study compared against
184 with our modeling results. The percentage deviation shows amount of variation between modeling
185 results with Qflow pressure results. The reason for deviation is due to conversion factor from
186 velocity to pressure values.

187
188 Conversion factor:
189 Input location: mean – 0.4cm/s = 0.03Volts – input voltage
190 Location 1- 0.2cm/s-0.015 volts
191 Location 2- 0.1cm/s-0.01 volts

192
193 Table 3: CAVM -MRA flow study for various phases & CSF region

194

Phase 3:			
Vessel locations as per figure 6	Flow outputs Mean velocity (in volts)	Electrical Network Modeling output	Deviation %
Input	0.03	0.0278	0.0022
Location 1	0.015	0.01	0.005
Location 2	0.01	2x10 ⁻⁴	0.0098

Phase - 8			
Vessel locations as per figure 6	Flow outputs Mean velocity (in volts)*	Electrical Network Modeling output	Deviation %
Input	0.35	0.337	0.013
Location 1	0.28	0.268	0.012
Location 2	0.19	0.178	0.012

3.2.2 2D-Perfusion validation:

2D Perfusion can be used for identification of perfusion alterations in blood vessel perfusion behavior e.g. in CAVM. The following are the list of parameters that are used for validation with modeling outputs:

- Model fit to the Time density Curve:

- Time of Arrival = t_0
- Time to Peak = $(t_1 + t_2) / 2$
- Wash-in rate:

$$r = \frac{f(t_0) - \frac{\int_{t_1}^{t_2} f(t) dt}{t_2 - t_1}}{t_p - t_0} = \frac{(t_2 - t_1)f(t_0) - \int_{t_1}^{t_2} f(t) dt}{(t_2 - t_1)(t_p - t_0)}$$

- Width = $(t_2+t_3)/2 - (t_0+t_1)/2$
- Area under Curve:

$$A = \int_{t_0}^{t_3} (f(t) - f_0) dt$$

- Mean Transit Time:

$$MTT = \frac{\sum_{i=0}^3 t_i f(t_i)}{\sum_{i=0}^3 f(t_i)}$$

These clinical parameters are the output of perfusion software. These parameters are converted in to the electrical equivalent for validation analysis, the details are as follows:

- Cerebral Blood flow (CBF) ~ Wash in Rate- Flow rate ~ current
- Cerebral Blood Volume (CBV) ~ Area under Curve / Width – velocity ~ pressure
- Mean Transit Time (MTT) ~ CBV / CBF = (Area under Curve / Width) / Wash in Rate-Friction coefficient ~ Resistance

The model is validated with 15 DSA data of CAVM patients. The results are nearly matching with an accuracy of 85%. The accuracy of modeling results is affected due to approximations in conversion of clinical to electrical parameters. Figure 7 shows snapshot of 2D-Perfusion along with clinical parameters.

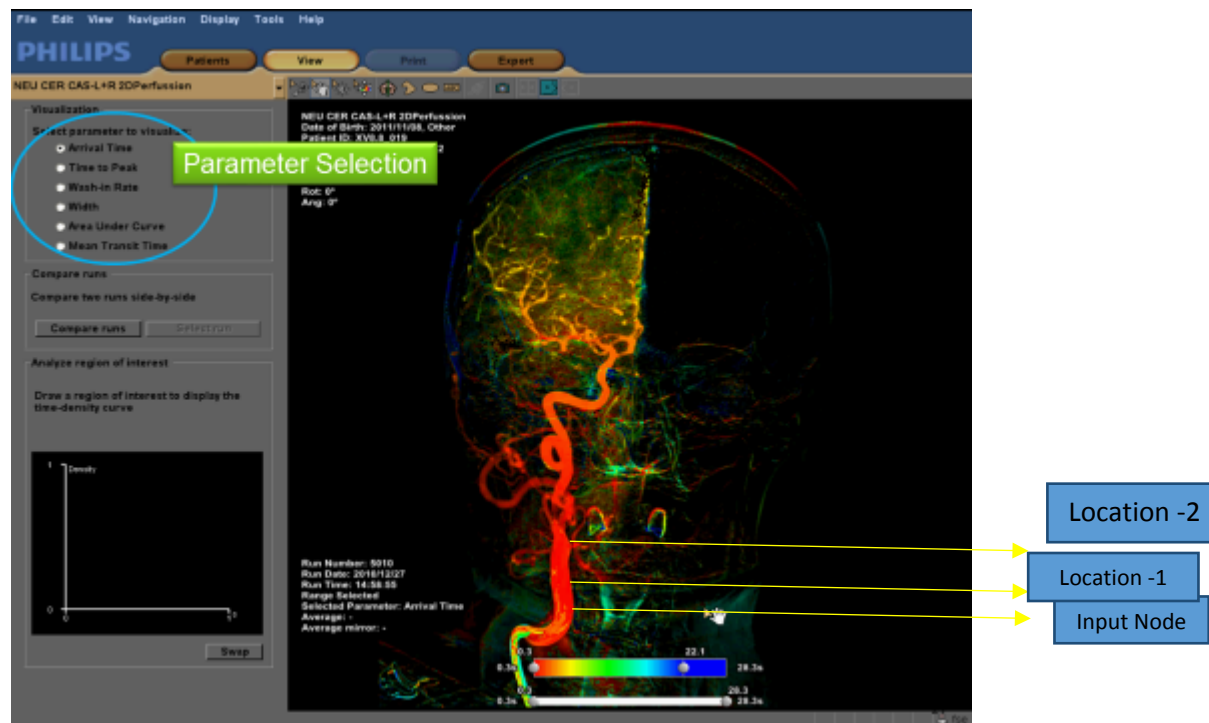

Figure 7- 2D-Perfusion analysis

Table 4 represents cross validation analysis for various vessel locations such as location -1, location-2 (refer figure 7). Modeling results are compared against 2D Perfusion software. The amount to percentage deviation is calculated for each cross validation comparison.

Table 4- 2D Perfusion – Cross validation.

Vessel location as per figure 7	Cerebral Blood Volume (Pressure volts) in	Electrical Network Modeling output	Deviation %
Input	0.12Volts	0.115Volts	4.1
Location 1	0.22 volts	0.209 volts	5
Location 2	0.43 volts	0.415 volts	3.4

Discussion:

The clinical procedure to measure hemodynamics in CAVM is invasive procedure. The current procedure is risky, as catheter may rupture, can cause patient death [Erzhen Gao a, William L.

Young 1998; WayneWakeland 2008.]. The -researchers explained different models based on invasive techniques for hemodynamics analysis [Cattivelli 2008] but limited by measurement of radius calculation for specific arteries. Kuebler analyzed the regional cerebral blood flow based on non-invasive technique, however limited by cerebral circulation only. Kienzler et al analyzed various methods for validation of noninvasive pressure measurements, but limited by data points.

The proposed non-invasive methodology address the clinical procedure to measure hemodynamics, by simulating the actual patient condition using lumped model. The modeling results are validated with clinical invasive measurements. Our results show that simulated results are approximately matching with the actual clinical measurements .The reason for deviation is due to conversion factor from velocity to pressure values. A total of 30 CAVM patients and 150 vessel locations were validated with invasive measurements and with cross validation (Qflow). The statistical analysis shows mean square error rate for 150 vessel locations is less than 0.05, shows a statistically significant evidence. The modeling results is approximately matching with Qflow results. The reason for deviation is due to conversion factor from pressure to velocity parameter.

In validation of 2D-Perfusion, the data is limited to 15 DSA images, as this software requires specific type of DSA acquisition to process. With the 15 patients, we validated and quantified our modeling results with 2D-Perfusion. The results are nearly matching with accuracy of 85%. The reason for deviation of modeling results with 2D perfusion is due to approximation of parameters used for modeling.

The cross validation is a novel approach for CAVM validation. Qflow and 2D-perfusion software's implementation is based on mechanical simulation. The lumped modeling results nearly matching with Philips propriety software's, confirms the matching of results between electrical and mechanical simulation. To reach significant evidence>98%, we require more data for our validation work. The limitation of this work, is the usage of multiple approximated conversions of application specific compared against modeling results. This work can be extended for different geometry using three dimensional volume data and require optimization of conversion factors to increase the accuracy of modeling results.

Conclusion:

In this paper, we have validated CAVM modeling results, created using lumped networks with clinical measurements and with cross validation techniques. The new approach for cross-validation is proposed in this paper. The modeling results by validating our results with validated product in clinical environment. The results are validated for 30 CAVM patients with 150 vessel locations validation shows nearly matching significantly results compared to the invasive measurements and with Philips propriety validated software's. This method seems to be safe and reliable.
