**Purpose** To clarify the outcome of flexible ureteroscopy for management of renal calculi without preoperative stenting. **Methods** A total of 171 patients who received 176 flexible ureteroscopy procedures for unilateral renal stones were reviewed. All procedures were divided into two groups depending on whether they received ureteral stenting preoperatively. Baseline characteristics of patients, stone burden, operation time, stone free rates, and complications were compared between both groups. **Results** Successful primary access to the renal pelvis was achieved in 104 of 114 (91.2%) patients without preoperative stenting, while all procedures with preoperative stenting (n=62) were successfully performed. A Total of 156 procedures were included for further data analysis (56 procedures in stenting group and 100 in non-stenting group). No significant differences was found regardless of a preoperative stent placement in terms of stone free rate (73.2% with stenting vs. 71.0% without,  $P=0.854$ ), operative time ( $70.4\pm32.8$  with stenting vs  $70.2\pm32.1$  without,  $P=0.969$ ). **Conclusions** Flexible ureteroscopy for management of renal stone without preoperative ureteral stenting are associated with well outcome in short term follow-up. Our study may help patients and doctors to decide if an optional stent is placed or not.

16 **Abstract**

17 **Purpose** To clarify the outcome of flexible ureteroscopy for management of renal calculi without  
18 preoperative stenting.

19 **Methods** A total of 171 patients who received 176 flexible ureteroscopy procedures for unilateral  
20 renal stones were reviewed. All procedures were divided into two groups depending on whether  
21 they received ureteral stenting preoperatively. Baseline characteristics of patients, stone burden,  
22 operation time, stone free rates, and complications were compared between both groups.

23 **Results** Successful primary access to the renal pelvis was achieved in 104 of 114 (91.2%)  
24 patients without preoperative stenting, while all procedures with preoperative stenting (n=62)  
25 were successfully performed. A Total of 156 procedures were included for further data analysis  
26 (56 procedures in stenting group and 100 in non-stenting group). No significant differences was  
27 found regardless of a preoperative stent placement in terms of stone free rate (73.2% with  
28 stenting vs. 71.0% without,  $P=0.854$ ), operative time ( $70.4\pm32.8$  with stenting vs  $70.2\pm32.1$   
29 without,  $P=0.969$ ).

30 **Conclusions** Flexible ureteroscopy for management of renal stone without preoperative ureteral  
31 stenting are associated with well outcome in short term follow-up. Our study may help patients  
32 and doctors to decide if an optional stent is placed or not.

### 33 **Introduction**

34 Improvement of the instruments as well as endoscopic technology has made fURS as an  
 35 increasingly popular treatment option for patients with renal stones [1-3]. Indication for fURS  
 36 also has been extended, even for stone larger than 2cm [4, 5]. Preoperative stenting is frequently  
 37 used to allow passive ureteral dilatation, which is supposed to facilitate the passage of a flexible  
 38 ureteroscope or ureteral access sheath (UAS). In a study, double-J stent inserted 5-10 days before  
 39 fURS was recommended as a part of standardized technique to achieve superior results for  
 40 treatment of renal stones [6]. However, a preoperative stenting inevitably leads extra cost and  
 41 time, as well as complications such as flank pain, sexual dysfunction, bothersome urinary  
 42 symptoms and potential urinary tract infection [7-9]. Then, patient compliance is an issue for  
 43 urologists. In addition, urologists have better skill and more confidence to successfully perform  
 44 fURS procedures for patients without preoperative stenting with increased experience. For the  
 45 above reasons, more and more fURS procedures without preoperative stenting were carried out in  
 46 our department.

47 However, the outcome of Flexible Ureteroscopic Treatment for renal stones without preoperative  
 48 stenting is undefined. Hence, we reviewed a series of cases to seek the answer.

## Material and Methods

This study was approved by the ethics committee of Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology. All unilateral fURS procedures from between June 2013 and May 2015 were reviewed. All patients included underwent fURS as initial attempt or substitute for previous failed ESWL or PCNL procedures to treat solitary as well as multiple renal calculi. The patients with the presence of ipsilateral ureteral stones were excluded. All patients were classified into two groups depending on whether they received a preoperative stent. The patients in stenting group received preoperative stenting (5~8F) for persistent renal colic, fever, insufficient renal function, or just to dilate the ureter to facilitate subsequent fURS. The patients in non-stenting group had not received stenting before fURS.

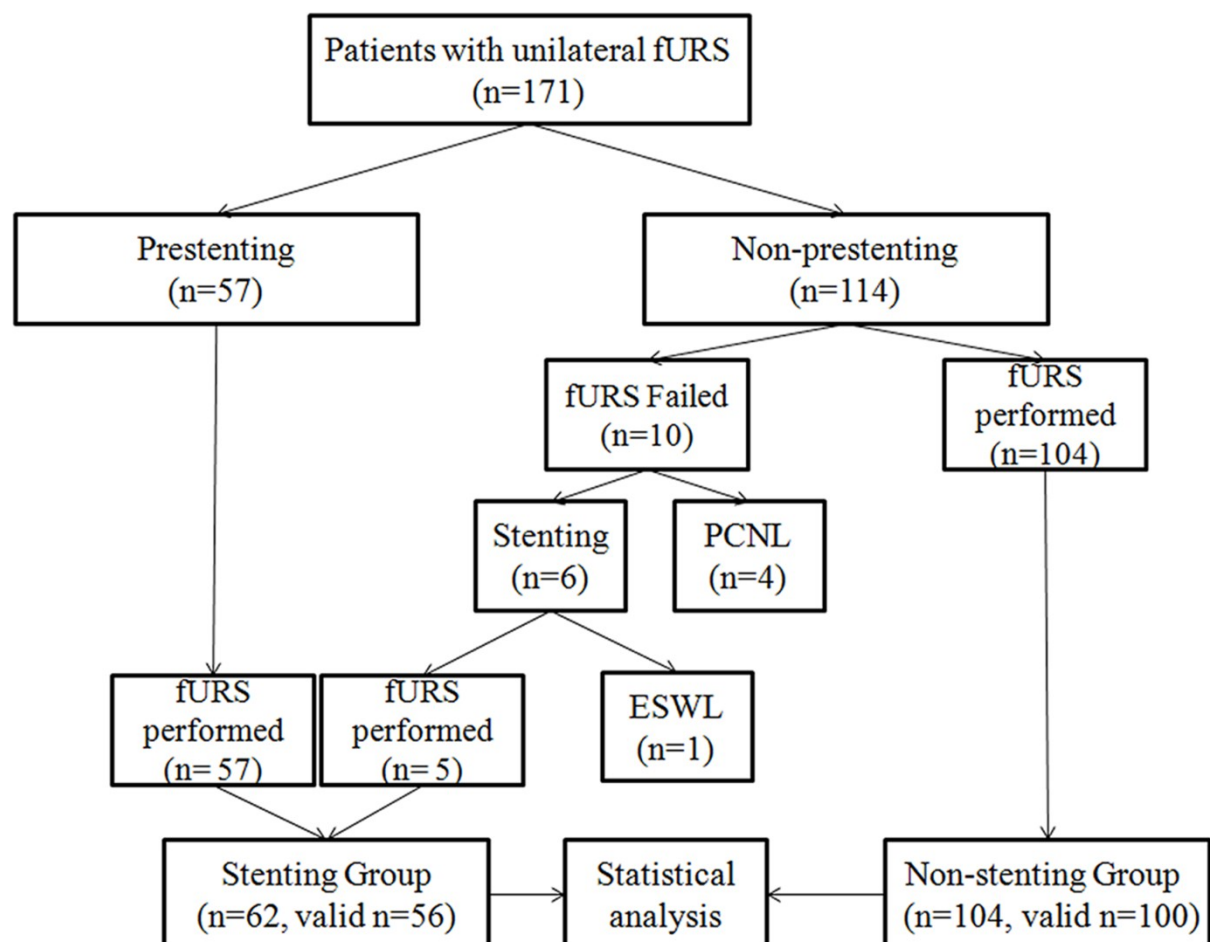

All procedures were performed by experienced urologists in our department according to standard operative protocols. Urinary tract infection was controlled before all operations. For patients with preoperative stenting, firstly the stents was removed through ureteroscopy (URS) or cystoscopy. And for patients without preoperative stenting, a rigid URS was performed to detect the whole ureter at first. Then a guidewire was inserted into ureter and UAS (12/14F, Cook) was placed routinely. A 7.5F flexible ureteroscope (Storz, Germany) with a 200μm laser fibre was used for laser lithotripsy. Nitinol stone retrieval baskets were also used if necessary at surgeon discretion. All patients received ureteral stent at the end of operations. Then all patients underwent KUB or non-contrast CT about 4 weeks and 3 months after treatment, and absence of any stone or residual stone fragment  $\leq 4\text{mm}$  was considered as stone free.

69 We retrospectively recorded data from patient documentation, radiologic images (including X-  
70 ray, IVU, and computed tomography), reports of anaesthesia and operation. All radiologic images  
71 were checked collaboratively by an urologist and a radiologist. Number, location and linear  
72 diameter of stones visible in radiologic images were noted in detail. Fever was defined as  
73 postoperative body temperature  $\geq 38$ . The procedures were performed by a total of five urologists.

74 Statistical analysis was performed by Statistical Package for the Social science version 13.0.  
75 Continuous variables with normal distribution and without normal distribution were performed  
76 with Student's *t*-test and Mann-Whitney U-test, respectively. Categorical variables were  
77 performed with chi-squared test or Fisher's exact test. Potential factors associated with stone free  
78 rate including BMI(kg/m<sup>2</sup>), stone size (mm), stone number, presence of preoperative stenting,  
79 type of anaesthesia and presence of hydronephrosis were analyzed by multivariate logistic  
80 regression analysis. A *P* value of  $< 0.05$  was considered statistically significant.

# 81 Results

82 A total of 176 unilateral procedures of fURS from 171 individual patients were included. The  
 83 figure 1 shows the clinical outcome of all patients. Majority (104 of the 114) of the patients  
 84 without a preoperative stent were successfully performed fURS, while the left 10 patients  
 85 underwent a failed attempt for access to the renal pelvis was not achieved. Of the 10 patients, five  
 86 patients received a stent placement and subsequent fURS, 4 patients underwent a conversion to  
 87 PCNL procedure, and one patient received a stent followed by ESWL treatment. All of 62 patients  
 88 with a preoperative double-J stent (including the above mentioned five patients who received a  
 89 stent in first failed attempt) were successfully performed fURS (figure 1).

90 Figure 1. Flow diagram and patient disposition.(fURS= flexible ureteroscopy; ESWL=

91 Extracorporeal shock wave lithotripsy; PCNL= Percutaneous nephrolithotomy)

92 As the figure 1 showed, a total of 166 procedures successfully entered into renal pelvis to  
 93 perform fURS lithotripsy. Of the 166 procedures, ten procedures with incomplete data were not  
 94 enrolled for further data analysis. There were no statistically significant differences between  
 95 preoperative stenting group (n=56) and non-stenting group (n=100) in terms of age, gender, side,  
 96 BMI, presence of hydronephrosis, type of anaesthesia, operation time. Stone number, stone site,  
 97 and stone burden were also similar in both groups. Positive rate of preoperative urine culture was  
 98 higher in stenting group. Stone free rate was similar in both groups. Procedures for solitary stone  
 99 accounted for 71.2% (111 of 156). For single stone, stone free rate was highest for stone in renal  
 100 pelvis, and lowest in lower pole. Stone free rates were also similar for patients with solitary stone  
 101 in both groups (Table 1). Multivariate assessment revealed stone size rather than preoperative  
 102 stenting was the independent predictor of stone free rate after fURS in this study. (Table 2)

103 Table 1 Patient characteristics in stenting and non-stenting group

	Stenting group	Non-stenting group	P
Procedures	56	100	
Age (year)	51.4±12.8	47.6±13.2	0.080

	73.2% (41/56)	71.0% (71/100)	0.854
For Solitary stone			
	85.0%(34/40)	77.5%(55/71)	0.458

104 Table 2. Result of multiple logistic regression analysis to determine factors associated with stone  
105 free rate.

Variable	Category	OR	95%CI	p value
BMI(kg/m <sup>2</sup> )		1.027	0.899-1.173	0.699
Stone size (mm)		0.407	0.206-0.807	0.010
Stone number	1 vs ≥2	0.423	0.147-1.216	0.110
Preoperative stenting	Present vs absent	0.799	0.333-1.919	0.616
Anaesthesia	General vs epi	0.907	0.392-2.101	0.820
Hydronephrosis	Absent vs present	1.070	0.448-2.558	0.879

106 Complication rates were low in both groups except for fever. Surprisingly, up to 17.9% of  
107 patients with preoperative stent experienced fever postoperatively. Patients without preoperative  
108 stenting had a much lower incidence of fever compared with that (6% vs. 17.9%,  $P = 0.027$ ).  
109 Perforations of renal pelvis or ureter were more common for patients without a preoperative stent,  
110 and were low in both groups. All perforations were not severe, and treated with a postoperative  
111 stent. No complications of ureter avulsion occurred in both groups. Severe complications such as  
112 bleeding with transfusion or urosepsis were rare. (Table 3)

113 Table 3 Comparisons of postoperative complications between both groups according to the  
114 Clavien-Dindo classification

pelvis /Ureter perforation				
Transfusion	(Grade II)	1(1.8%)	0	
Urosepsis	(Grade IVb)	1(1.8%)	1(1%)	

# Discussion

As one of common available treatment options, fURS has occupied more and more positions formerly held by PCNL and ESWL. However, limited data have been referred to the role of preoperative stenting in the treatment of renal calculi by fURS [10-14]. Shields et al reviewed a cohort of patients undergoing URS for upper urinary tract calculi and concluded that preoperative stent was positively associated with success, however, without statistical significance [11]. Lumma et al analyzed data of 550 ureterorenoscopies treated for stones in ureter and renal pelvis. Data indicated that patients with preoperative stent had improved results in stone free rate and complication rate apart from distal ureteral stones [10]. Kawahara et al analyzed 51 patients with large (> 15mm) stone, and concluded that ureteroscopy success rate was higher in the stenting group and may improve SFR [13]. However, most studies were referred to patients with ureteral and renal calculi, and instruments and methods applied for ureteral calculi are quite different from renal calculi. In addition, fURS occasionally will not pass beyond the ureter to reach renal pelvis, which have been mentioned limitedly [15-17]. Therefore, the aim of this study was to systematically clarify the surgical outcome of fURS without preoperative stenting for renal calculi.

Of the 114 patients without preoperative stenting, 10 patients underwent a failed procedure for

access to the renal pelvis was not achieved. In these patients, a narrow ureteric lumen or tortuous ureter caused the failure of access, even though no evidence of obstruction in ureter was found preoperatively or intraoperatively. Half of the 10 patients received a ureteral stent for a period of time (7~40d) and underwent a second attempt in which narrow ureteric lumen or tortuous ureter disappeared. Obviously, the preoperative stenting passively dilated the ureter and facilitated access to renal pelvis in them. A study by Ambani et al retrospectively analyzed 41 patients who underwent ureteral stenting after an initial failed attempt of fURS. The second fURS was performed in these patients after 4 to 34 days and succeeded in 38 patients (93%) [15]. Therefore, when a difficult ureter was faced in first attempt of fURS, placement of a stent and subsequent second attempt was optional and even encouraged. In our study, stone free rate (3 months after operation) in patients with preoperative stenting was higher compared to patients without preoperative stenting, however without statistical significance (73.2%% vs. 71.0%,  $P = 0.0854$ ). This result was not consistent with some previously published data [10, 11, 18]. One possible reason was that ureteral stones account for a high proportion of all stones in these studies. Multivariate assessment also revealed that preoperative stent was not the independent predictor of stone free rate after fURS in our study which was similar with a previous study [19]. In our opinion, once the fURS successfully arrived at renal pelvis, stone free rate for renal calculi would be more likely affected by stone characteristics and pelvicalyceal anatomy rather than the existence of preoperative stenting according to our experience and some published data [20-22].

Stone free rate was not very high in our study. One reason may be that stone size ( $18.4 \pm 7.7$  mm)

in our study was higher than many studies [6, 23, 24]. Although non-contrast CT was the most accurate modality for follow-up of urolithiasis, we also performed KUB for follow-up for its advantages of less cost and radiation exposure.

The operation time was similar in both groups. However, different results had been reported. Lumma et al found that the operation time in patients with preoperative stent was extended by 4.9 min compared to patients without stent, and attributed this to stent extraction [10]. Another study indicated that preoperative stenting decreased operative time of URS for stones (mainly in the ureter). The possible reason may be that preoperative stenting dilated the ureter and allowed a bigger ureteral access sheath and better irrigation [18]. In our experience, it would consume some time to remove preexist stents, however, a procedure of rigid URS was not necessary before placing the UAS in these patients generally.

Severe complications were rare in our study, however, postoperative fever rate was much higher compared with other complications. And patients with preoperative stenting had a higher incidence of fever compared with without (17.9% vs. 6.0%,  $P=0.027$ ). The reason may be that majority of patients with preoperative stenting in this study received a stent just because of existence of fever or urinary tract obstruction and patients in stenting group indeed had a significant higher rate of positive urine culture. So we could not conclude that preoperative stenting increased postoperative fever rate, although an extended time of stenting may cause potential urinary tract infection (UTI) [25]. And the incidence of fever in our patients without preoperative stenting was similar with the results (3.6% for 10-20mm renal stones) of CROES

173 URS Global Study [20].

174 Perforations of ureter or pelvis were not very common in both groups (1.8% with stent vs. 4%  
 175 without). Actually, as many mild injuries may be ignored in records of our operations, it was hard  
 176 to know accurate incidence of ureter injuries for all patients. We speculated that ureter injuries  
 177 (especially for mild injuries) were common according to our experience as well as published data  
 178 [26]. However, severe ureter injuries such as ureter avulsion never happened. In our experience,  
 179 if unreasonable resistance was perceived when passing through the ureter, it was better to  
 180 terminate the fURS procedure rather than try with a greater force to avoid severe ureter injury. As  
 181 many above mentioned substitutes could be selected subsequently, an “adventure” was not  
 182 necessary.

183 A recent published large scale study included 1622 patients with renal stones who were treated  
 184 with fURS and concluded that preoperative stent increased stone free rates (79.6% with stent vs.  
 185 72.9% without stent) and decreased intraoperative complications [27]. The results of this large  
 186 scale study are very valuable, however, we still should note that heterogeneity of reasons for  
 187 preoperative stenting may affect outcome of fURS for renal stones in different studies. And this  
 188 large scale study indicated that non-stenting fURS for renal stones may have some disadvantages,  
 189 however, it still had an acceptable prognosis. In addition, it should be emphasized that non-  
 190 stenting procedures would benefit patients for less cost and suffering.

191 Our study has some limitations. First, it is a retrospective study from single center. Second, the

192 complications mentioned in our study were early stage complications, while late complications  
 193 such as ureter stricture were not concerned due to limited follow-up time. Despite these facts, our  
 194 study is one of the largest series to determine the prognosis of non-stenting procedure on  
 195 management of renal calculi with fURS.

196 Our study showed that majority(91.2%, 104 of the 114) of the patients without preoperative  
 197 stenting were successfully performed fURS at first attempt. The procedures of Non-stenting  
 198 fURS for renal stones have an acceptable prognosis compared with the stenting group in our  
 199 study. If a preoperative stenting is optional, our study may help the patients and clinicians make a  
 200 final decision. And large prospective randomized controlled studies are required to further figure  
 201 out the role of pre-stent, especially for optional cases.
