Video playback is becoming a common method for manipulating social stimuli in experiments. Parid tits are one of the most commonly studied groups of wild birds. However, it is not yet clear if tits respond to video playback or how their behavioural responses should be measured. Behaviours may also differ depending on what they observe demonstrators encountering. Here we present blue tits (*Cyanistes caeruleus*) videos of demonstrators discovering palatable or aversive prey (injected with bitter-tasting Bitrex) from coloured feeding cups. First we quantify variation in demonstrators' responses to the prey items: aversive prey provoked high rates of beak wiping and head shaking. We then show that focal blue tits respond differently to the presence of a demonstrator on a video screen, depending on whether demonstrators discover palatable or aversive prey. Focal birds faced the video screen more during aversive prey presentations, and made more head turns. Regardless of prey type, focal birds also hopped more frequently during the presence of a demonstrator (compared to a control video of a different coloured feeding cup in an empty cage). Finally, we tested if demonstrators' behaviour affected focal birds' food preferences by giving individuals a choice to forage from the same cup as a demonstrator, or from the cup in the control video. We found that only half of the individuals made their choice in accordance to social information in the videos, i.e. their foraging choices were not different from random. Individuals that chose in accordance with a demonstrator, however, made their choice faster than individuals that chose an alternative cup. Together, our results suggest that video playback can provide social cues to blue tits, but individuals vary greatly in how they use this information in their foraging decisions.

19 **ABSTRACT**

20 Video playback is becoming a common method for manipulating social stimuli in experiments.  
21 Parid tits are one of the most commonly studied groups of wild birds. However, it is not yet clear  
22 if tits respond to video playback or how their behavioural responses should be measured.  
23 Behaviours may also differ depending on what they observe demonstrators encountering. Here we  
24 present blue tits (*Cyanistes caeruleus*) videos of demonstrators discovering palatable or aversive  
25 prey (injected with bitter-tasting Bitrex) from coloured feeding cups. First we quantify variation  
26 in demonstrators' responses to the prey items: aversive prey provoked high rates of beak wiping  
27 and head shaking. We then show that focal blue tits respond differently to the presence of a  
28 demonstrator on a video screen, depending on whether demonstrators discover palatable or  
29 aversive prey. Focal birds faced the video screen more during aversive prey presentations, and  
30 made more head turns. Regardless of prey type, focal birds also hopped more frequently during  
31 the presence of a demonstrator (compared to a control video of a different coloured feeding cup in  
32 an empty cage). Finally, we tested if demonstrators' behaviour affected focal birds' food  
33 preferences by giving individuals a choice to forage from the same cup as a demonstrator, or from  
34 the cup in the control video. We found that only half of the individuals made their choice in  
35 accordance to social information in the videos, i.e. their foraging choices were not different from  
36 random. Individuals that chose in accordance with a demonstrator, however, made their choice  
37 faster than individuals that chose an alternative cup. Together, our results suggest that video  
38 playback can provide social cues to blue tits, but individuals vary greatly in how they use this  
39 information in their foraging decisions.

42

43

**44 INTRODUCTION**

45 Potential prey items differ in their nutritional benefits and palatability (Skelhorn, Halpin & Rowe,  
46 2016). Therefore, when foraging, animals face decisions that require an estimation of the  
47 profitability of prey (Pyke, Pulliam & Charnov, 1977), in order to maximize their fitness. As well  
48 as learning from their own experience with prey (Skelhorn, Halpin & Rowe, 2016), predators can  
49 gather social information from observing the foraging experiences of others (Galef & Giraldeau,  
50 2001). For example, observing conspecifics consuming palatable food positively influences food  
51 preferences in many avian species (Mason & Reidinger, 1981; McQuoid & Galef, 1993; Fryday  
52 & Greig-Smith, 1994). However, the potential for information to be available from observing an  
53 encounter with less palatable prey has received far less attention.

54

55 Many bird species show a clear disgust response by vigorously wiping their beaks on a perch  
56 (Clark, 1970; Ganchrow, Steiner & Bartana, 1990). This cue might provide social information  
57 about the profitability of food resources to others: for example, young chicks that observe beak  
58 wiping and head shaking are less likely to peck at, or consume, the same foods (Johnston, Burne  
59 & Rose, 1998; Skelhorn, 2011) and red-winged blackbirds will avoid feeding cups if demonstrators  
60 are induced to vomit after eating (Mason & Reidinger, 1982). Parid tits are one of the most studied  
61 wild birds in Europe, with an increasing focus on their social behavior and learning (e.g. Sasvári,

62 1979, Marchetti & Drent, 2000; Aplin, Sheldon & Morand-Ferron, 2013). While previous studies  
63 have shown that Parid tits can learn a novel foraging task by observing other individuals (Sasvári,  
64 1979, Aplin, Sheldon & Morand-Ferron, 2013), it is not yet known how they use social information  
65 about food palatability in their foraging decisions.

66

67 Our first aim was to investigate how wild-caught blue tits use information from foraging  
68 conspecifics, and if their response differs depending on the palatability of food that demonstrators  
69 encounter. However, when studies involve experimentally manipulating social behaviour, it can  
70 be difficult to control what stimuli focal birds observe (McQuoid & Galef, 1993). Issues can also  
71 arise because of social characteristics of the birds themselves (e.g. dominance, Nicol & Pope,  
72 1999). Video playback might circumvent these issues and provide many advantages over live  
73 demonstrators. With videos, it is possible to manipulate the characteristics presented and control  
74 the timing of the video presentation, thus enabling controlled and standardized stimuli to be  
75 presented to focal individuals (D'Eath, 1998, Woo & Rieucou, 2011). Furthermore, use of video  
76 playback also has ethical implications. For instance, using video playback to study how individuals  
77 use social information about food palatability requires fewer demonstrators to be encouraged to  
78 eat unpalatable food (e.g. Mason & Reidinger, 1982).

79

80 Video playback also has potential shortcomings, however, that should be considered when  
81 using these stimuli in behavioural studies (D'Eath, 1998, Woo & Rieucou, 2011). For instance, in  
82 many species, physical interactions between an observer and a demonstrator play an important role  
83 in certain behaviours, such as in aggressive contests and courtship, so the applicability of video  
84 playback in these contexts may be limited (D'Eath, 1998). To be able to study focal individuals'

85 responses to specific stimuli, we also need to be sure that individuals pay attention to subtleties in  
86 demonstrators' behaviour instead of simply responding to their presence in a video (McQuoid &  
87 Galef, 1993). To date, video presentations have been used successfully in both captive (Rowland  
88 et al., 1995; Ord et al., 2002; Bird & Emery, 2008) and field studies (Clark, Macedonia &  
89 Rosenthal, 1997; Burford, McGregor & Oliveira, 2000; Gunhold, Whiten & Bugnyar, 2014) across  
90 different contexts, including studies of mate preference (e.g. Ophir & Galef, 2003), social learning  
91 (e.g. McQuoid & Galef, 1993), and predator recognition (e.g. Evans, Macedonia & Marler, 1993),  
92 and for a range of taxa, including mammals (Gunhold, Whiten & Bugnyar, 2014), fish (Rowland  
93 et al., 1995), lizards (Ord et al., 2002), spiders (Clark & Uetz, 1992), and birds (Rieucou &  
94 Giraldeau, 2009; Zoratto et al., 2014). Surprisingly, however, the validity of video playback has  
95 not been tested for Parid tits. Therefore, the second aim of our study was to investigate its  
96 applicability.

97

98 In this study, we presented focal birds with videos of a demonstrator encountering palatable  
99 and aversive prey items in novel, coloured feeding cups. We first quantified variation in  
100 demonstrator blue tits' behaviour when encountering these two prey types before presenting  
101 standardized videos of these encounters to focal birds. These videos also included a control section  
102 that consisted of a different coloured feeding cup in an empty cage; we predicted that individuals  
103 would pay more attention to the videos when a conspecific was present. The control section was  
104 presented to focal birds both before and after a demonstrator appeared on the screen to investigate  
105 if birds' response to control cups would change after they had seen a demonstrator foraging from  
106 a different cup. Because demonstrators were more active during the encounter with aversive prey,

107 we also predicted that this might provide more cues and therefore elicit more vigorous response in  
108 focal birds, compared to a video of palatable prey.

109

110         Recent studies have shown that acquiring information by observing others does not always  
111 result in use of that social information (Carter et al., 2014, Mesoudi et al., 2016). To investigate  
112 whether video playback can be used to manipulate social information for blue tits, we used a simple  
113 choice test to record if observers preferred to feed from a similarly coloured cup as the  
114 demonstrator, or from the different coloured cup (present in the control video). We predicted that  
115 focal birds observing a demonstrator encountering a palatable prey, would choose to feed from the  
116 same cup as the demonstrator, whereas observation of an encounter with aversive prey would lead  
117 them to avoid the cup in which the demonstrator found the distasteful prey item.

118

119         Finally, familiarity with the demonstrator may influence responses to playback. Previous  
120 studies have shown that Japanese quail (*Coturnix japonica*) females identify specific males that  
121 they see in videos (Ophir & Galef, 2003), and that rooks (*Corvus frugilegus*) spend more time  
122 looking at a video of their partner, compared to a video of a nonaffiliated conspecific (Bird &  
123 Emery, 2008). The value of social information may also vary depending on familiarity (Firth,  
124 Sheldon & Farine, 2016, Mesoudi et al., 2016), or previous experiences (Farine, Spencer &  
125 Boogert, 2015), with the demonstrator. We attempted to account for this by including a measure  
126 of association strength from our study population's social network, and predicted that the identity  
127 of the demonstrator would influence the behavioural responses of observers.

128

## 129 **METHODS**

130 *Birds and housing*

131 The study was conducted from January to March 2016 at Madingley Wood (0°3.2'E, 52°12.9'N),  
132 an established study site in Cambridge. There is an ongoing long-term study of great tit and blue  
133 tit populations in the area and birds have been given British Trust of Ornithology (BTO) ID rings  
134 and fitted with small passive integrated transponder (PIT) tag fitted to a colour ring since 2012. In  
135 January, five sunflower seed feeders were fitted with PIT tag reading antennae and data loggers  
136 that scanned birds' unique PIT tag codes when they landed on a feeder. During the winter great  
137 tits and blue tits form loose fission-fusion flocks that move between food sources (Ekman, 1989).  
138 This flocking behaviour allows us to use the records from the feeders to identify individuals that  
139 forage in the same flock. We used a Gaussian mixture model to detect these gathering events  
140 (Psorakis et al., 2012), and then calculated social associations (i.e. edge weights in the social  
141 network) between individuals based on how often they were present in the same group (gambit of  
142 the group approach, Franks, Ruxton & James, 2010).

143

144 Wild blue tits ( $n = 25$ ) were captured with mist nets (by HMR) in February 2016. Individuals  
145 were chosen from the population randomly but PIT tag records enabled us to calculate association  
146 strengths for each observer- demonstrator pair used in the experiment. All captured birds were  
147 adults (based on plumage) but their sex was unknown. Birds were housed indoors in individual  
148 plywood cages (80 cm x 65 cm x 50 cm) with a daily light period of 12 hours. Food (sunflower  
149 seeds, peanuts and tallow) and water were provided ad libitum except prior and during the  
150 experiment when food restriction was necessary. This restriction lasted no longer than one hour,  
151 following guidelines to the operation of the Animal (Scientific Procedures) Act 1986 (2009), and  
152 the Association for the Study of Animal Behaviour's Guidelines for the treatment of animals in

153 behavioural research and teaching (2012). Birds were kept in captivity for a maximum of four  
154 days until released at the capture site, and they were in auditory (but not visual) contact during  
155 housing and experiments. The study was conducted under existing Home Office (PPL 60/4322)  
156 and Natural England (2015-6665-SCI-SCI-3) licenses held by HMR.

157

158 *Experimental protocol*

159 Prey types

160 We created two types of prey: a palatable mealworm and an aversive mealworm that was injected  
161 and coated with 2.5% solution of denatonium benzoate (Bitrex). Bitrex tastes bitter to humans  
162 (Chandrashekar et al., 2000) and elicits beak wiping in birds (Skelhorn & Rowe, 2009).

163

164 Video recording

165 We used six individual blue tits as demonstrators for the videos. Three of these birds were first  
166 used as observers in the social information use test before recording them as demonstrators. Birds  
167 were moved from their home cage to wooden test cages (66 cm x 50 cm x 50 cm) that differ from  
168 the home cage in that they have a front wall made of plexiglass. We coated the plexiglass with  
169 tinted film that made it possible to observe and film the birds while minimising effects on their  
170 behaviour

171

172 We first filmed the demonstrators eating a palatable mealworm in a coloured feeding cup  
173 (yellow or green). We then filmed the same individual eating a Bitrex mealworm in a different  
174 coloured cup (blue or purple). Because an experience of prey with chemical defences was likely

175 to affect birds' response towards palatable prey and their willingness to consume it, we always  
176 filmed responses towards palatable prey first.

177

178 From the videos, we quantified differences in demonstrators' response to palatable and  
179 aversive prey from first contact with the prey item until 10 seconds after eating. We measured (i)  
180 how long demonstrators spent wiping their beaks on a perch (in seconds), (ii) the number of beak  
181 wipes they performed, and (iii) the number of times the head was shaken. We then used these  
182 videos to create standardized videos to present to observers (see Videos S1 and S2).

183

#### 184 Video presentation

185 All videos included 45 seconds of a demonstrator finding a prey item in a coloured cup and  
186 a demonstrator's response to that prey. In addition, each video included 60 seconds of a different  
187 coloured cup in an empty cage to make sure that observers were familiar with both cup colours  
188 and their foraging choice would depend on the information in the video instead of novelty of cups.  
189 30 seconds of this control video was shown to observers before a demonstrator appeared on the  
190 screen and 30 seconds was shown after a demonstrator, as we predicted that observers might pay  
191 attention to the cups differently after seeing a foraging conspecific. We used green and yellow  
192 cups when demonstrators encountered palatable prey (randomizing which cup colour was shown  
193 with a demonstrator and which in an empty cage), and blue and purple cups when demonstrators  
194 encountered aversive prey. We showed each observer ( $n = 22$ ) two videos, once for each prey type.  
195 These two videos were shown on sequential days and the order was randomized among birds. We  
196 did not change the demonstrator between different prey types, so observers saw the same

197 demonstrator encounter both palatable and aversive prey. Therefore, we think that any differences  
198 in responses of the observers are likely due to the prey type, not the demonstrator's identity.

199

200 Observers were moved to a test cage 2 hr before the video presentations to allow habituation  
201 to the cage. We then placed a computer monitor (Dell 1908FPc, 19") against the plexiglass front  
202 wall of the cage for 15 minutes before showing the video (Fig. 1). This did not seem to stress the  
203 birds and they got used to the monitor quickly. We recorded observers during the video-playback  
204 (using a DBPOWER 1080P action camera; see Video S3), so that we could classify their behaviour  
205 during the different sections of the video playback: when they were shown i) cups before the  
206 demonstrator appeared (30 s), ii) the demonstrator's response to the prey (45 s), and iii) the same  
207 cups once the demonstrator was no longer present (30 s). From these recordings, we analyzed (i)  
208 the time that a bird spent facing the screen or flying, (ii) the number of head turns indicating  
209 increased vigilance, and (iii) the number of hops a bird performed on a perch, suggested to indicate  
210 increased nervousness such as neophobia (e.g. Heinrich, 1988).

211

212 The entire cage was not in the field of view of the camera, so sometimes birds flying close  
213 to the roof of the cage, or holding on near the roof, could not be seen in the video. Therefore, we  
214 excluded individuals from our dataset that were visible for less than 30 seconds during the whole  
215 105 seconds video (60 seconds of cups only and 45 seconds of a demonstrator). After removing  
216 these individuals, our dataset included 13 individuals that were shown videos of a demonstrator  
217 encountering both palatable and aversive prey, and 3 individuals that were visible only when they  
218 were shown a video of a demonstrator encountering palatable prey. The final sample size for video  
219 analysis was therefore 16 observers when prey was palatable (mean time that observers were

220 visible = 81 seconds, range = 38–105 seconds) and 13 observers when it was aversive (mean time  
221 that observers were visible = 90 seconds, range = 43–105 seconds).

222

### 223 Observer social information use test

224       Immediately following each session of video playback, we tested if focal birds (n = 22) used  
225 social information from the videos by giving them a choice between two different coloured cups:  
226 the cup that a demonstrator fed from, and the cup that was shown in an empty cage without a  
227 demonstrator (Fig. 1c). Both cups were filled with sand, so that birds could not see their contents  
228 and the time cost to search for prey was higher. Before the test, focal birds had been trained in  
229 their home cages to search for food hidden in the sand by offering them mealworms in a white  
230 feeding cup. Training was done stepwise, by first offering mealworms that were clearly visible,  
231 and then covering them partly with sand, until birds learned to search for worms that were  
232 completely hidden. Focal birds were therefore familiar with the foraging task in the experiment.  
233 We filmed the focal birds during the test and from these, recorded the time that it took birds to  
234 land on a first cup, and their choice. The test was finished after birds had landed on both cups, or  
235 after 20 minutes. Two birds in the palatable prey test and one individual in the aversive prey test  
236 did not land on either cup in 20 minutes, and were excluded from analyses.

237

### 238 *Statistical analyses*

239 All analyses were conducted using software R 3.2.2 (R Core Team, 2015). We used *asnipe* package  
240 (Farine, 2013) to construct a social network of wild great tit and blue tit populations. We first  
241 tested if the associations in the network were non-random by conducting permutation tests on the  
242 group matrix. The mean weighted degree of our network was significantly greater than values from

243 the permutations ( $p = 0.001$ ), demonstrating that our network differed significantly from random.  
244 We then calculated association between observers and demonstrators within our network of 331  
245 individuals (217 blue tits and 114 great tits). Association strengths were scaled between 0 (never  
246 observed in the same flock) and 1 (always observed in the same flock), and in our experiment,  
247 these values ranged from 0 to 0.070 (mean = 0.018, sd = 0.021). In addition, we calculated the  
248 total number of interactions (i.e. times observed in the same flock) between demonstrators and  
249 observers: these ranged from 0 to 107 (mean = 24, sd = 30.803). As both association measures  
250 gave similar results when analysing observer's behaviour, we decided to use only association  
251 strength in our final analyses.

252

253 We used a Wilcoxon signed ranked test to analyse differences in demonstrators' behaviour  
254 when encountering aversive or palatable prey, to allow for the small sample size ( $n = 6$ ). As the  
255 time that birds spent on foraging differed among demonstrators (palatable prey: range = 38–170  
256 seconds, median = 77 seconds; aversive prey: range = 16–115 seconds, median = 62 seconds) we  
257 first divided the time spent on beak wiping and a number of beak wipes and head shakes with the  
258 total time foraging, and then compared these rates between aversive and palatable prey.

259

260 For analyses of observers' behaviour, we next used generalized linear mixed effects models  
261 with appropriate error distributions, implemented using the *lme4* package (Bates et al., 2014).  
262 Explanatory variables in all models included an interaction between the effects of a demonstrator  
263 being present (cups before/demonstrator/cups after) with the prey type (palatable/aversive), the  
264 observer's association with its demonstrator as determined from the social network, and the test  
265 order (first/second test). In addition, we included an observer's identity and a demonstrator video

266 as random effects. The baseline level of each model included an initial cup presentation, aversive  
267 prey type, and a first video presentation. As the length of time that birds were visible in videos  
268 differed, we modeled the time observers faced the screen or spent flying versus the length of time  
269 observers performed other behaviours (i.e. total time visible – time facing a video or flying) as a  
270 bound response variable with a binomial error distribution. Similarly, we converted the number of  
271 head turns and hops into a rate by dividing the number of times they occurred by the total time a  
272 bird was visible. We then converted these rates to integers by multiplying them by 30 seconds,  
273 which was the most common length of time a bird was visible during each section of the videos.  
274 We modeled head turns using a Poisson error distribution, but hopping with a negative binomial  
275 error distribution as it was right-skewed.

276

277       Finally, we analysed if social information in the videos affected which cup observers landed  
278 on first and how fast they made their choice, using again generalized linear mixed effects models.  
279 To test the effects of video on birds' first choice, we included the choice (same/different cup that  
280 a demonstrator fed from) as a response variable, and prey type (palatable/aversive), the observer's  
281 association with its demonstrator, and the test order as explanatory variables, using binomial error  
282 distribution. The baseline level of the model included the video playback of aversive prey and a  
283 first video presentation. As the distribution of time before birds chose the cup was right-skewed,  
284 we modeled it with a negative binomial error distribution, using the time before a choice as a  
285 response variable, and an interaction between prey type (palatable/aversive), social information  
286 use (0/1, i.e. not matching/matching a demonstrator's behaviour), and the test order as explanatory  
287 variables. The baseline level of the model included the video playback of aversive prey, a first  
288 video presentation and individuals that did not match a demonstrator's behaviour. Bird identity

289 and a demonstrator video were included as random effects in both models. Most of the birds landed  
290 on a cup during the first five minutes after cups were presented. Two individuals, however, were  
291 considerably slower at choosing in the aversive prey test, and landed on a cup only after 15  
292 minutes. We therefore considered them as outliers, and removed them from the final analysis.

293

## 294 **RESULTS**

### 295 *Demonstrators' response*

296 Demonstrators responded differently to palatable and aversive prey. The time demonstrators spent  
297 wiping their beaks on a perch (Wilcoxon signed-ranked test,  $P = 0.03$ ) as well as the total number  
298 of beak wipes (Wilcoxon signed-ranked test,  $P = 0.03$ , Fig. 2a) were both significantly greater  
299 when demonstrators encountered aversive prey (time spent on beak wiping: median = 14 seconds,  
300 range = 4–23 seconds; number of beak wipes: median = 49, range = 20–107), compared to  
301 palatable prey (time spent on beak wiping: median = 1.5 seconds, range = 0–5 seconds; number of  
302 beak wipes: median = 5.5, range = 0–17). Demonstrators also performed more headshakes when  
303 eating aversive prey (median = 17.5, range = 5–27) than when eating palatable prey (Wilcoxon  
304 signed-ranked test,  $P = 0.03$ ; Fig. 2b; median = 0, range = 0–5).

305

### 306 *Focal birds' response to video-playback*

#### 307 Facing the screen

308 The time observers faced the video screen depended on the prey type a demonstrator encountered  
309 (Fig. 3a): observers faced the screen less during (demonstrator presence \* prey type; estimate = -

310  $0.836 \pm 0.252$ ,  $Z = -3.320$ ,  $p < 0.001$ ) and after (cups after demonstrator playback \* prey type:  
311 estimate =  $-0.570 \pm 0.269$ ,  $Z = -2.118$ ,  $p = 0.03$ ) the presentation of palatable prey compared to  
312 aversive prey. There were no significant differences between video types in the way observers  
313 responded to cups only before the presentation of a demonstrator (estimate =  $0.318 \pm 0.720$ ,  $Z =$   
314  $0.441$ ,  $p = 0.66$ ), suggesting that it was the behaviour of the demonstrator that influenced how long  
315 observers faced the video screen. Following presentation of any demonstrators, observers paid  
316 overall less attention to the screen showing cups only (estimate =  $-0.392 \pm 0.181$ ,  $Z = -2.167$ ,  $p =$   
317  $0.03$ ; Fig. 3a). Focal birds also faced the screen more during the second test (estimate =  $0.386 \pm$   
318  $0.144$ ,  $Z = 2.679$ ,  $p = 0.007$ ). In addition, association strength with a demonstrator had a significant  
319 effect on focal birds' behaviour, showing that individuals faced the screen less when they were  
320 more closely associated with a demonstrator (estimate =  $-28.099 \pm 12.296$ ,  $Z = -2.285$ ,  $p = 0.022$ ).  
321 The distribution of association scores, however, was skewed, as most of the individuals had low  
322 association scores with a demonstrator, and it is therefore difficult to interpret this result. Finally,  
323 bird identity (variance = 0.674) and demonstrator video (variance = 1.417), included to the model  
324 as random effects, explained some of the observed variation. The final model is presented in  
325 Supplemental information (File S1, Table 1).

326

### 327 Flying

328 Although observers varied in how much time they spent flying during video playback (range = 0–  
329 29 seconds, mean = 4.8 seconds), there was no effect of demonstrator presence and prey type on  
330 this behaviour (compared to initial cup presentation, demonstrator present \* prey type: estimate =  
331  $0.185 \pm 0.289$ ,  $Z = 0.640$ ,  $p = 0.52$ ; cups after demonstrator playback \* prey type: estimate =  $0.169$   
332  $\pm 0.310$ ,  $Z = 0.544$ ,  $p = 0.59$ ) and their interactions were therefore removed from the final model.

333 The final model shows that a demonstrator's presence, regardless of prey type (estimate = -0.248  
334  $\pm 0.144$ ,  $Z = -1.729$ ,  $p = 0.16$ ), the test order (estimate =  $0.114 \pm 0.158$ ,  $Z = 0.718$ ,  $p = 0.47$ ) or the  
335 association between observer and demonstrator (estimate =  $14.913 \pm 13.957$ ,  $Z = 1.069$ ,  $p = 0.29$ )  
336 did not affect the time that observers were flying during video playback, but random effects  
337 explained some of the observed variation (variance for bird identity = 0.908; variance for  
338 demonstrator video = 0.987; Table 2 in File S1).

339

#### 340 Head turns

341 The number of head turns observers performed depended on a demonstrator's presence in the video  
342 and prey type a demonstrator encountered (Fig. 3b). Observers performed less head turns during  
343 (demonstrator presence \* prey type; estimate =  $-0.393 \pm 0.196$ ,  $Z = -2.002$ ,  $p = 0.045$ ) and after  
344 (cups after demonstrator playback \* prey type: estimate =  $-0.543 \pm 0.199$ ,  $Z = -2.726$ ,  $p = 0.006$ )  
345 the presentation of palatable prey compared to aversive prey. During the initial cup presentation  
346 observers' responses did not differ significantly between these video types (estimate =  $0.015 \pm$   
347  $0.278$ ,  $Z = 0.055$ ,  $p = 0.96$ ). The test order (estimate =  $0.188 \pm 0.141$ ,  $Z = 1.337$ ,  $p = 0.181$ ), or  
348 association between demonstrator and observer (estimate =  $-8.142 \pm 5.062$ ,  $Z = -1.608$ ,  $p = 0.11$ )  
349 had no effect on the number of head turns performed, and also the variance estimates for the  
350 random effects were small (variance for bird identity = 0.081; variance for demonstrator video =  
351 0.158; Table 3 in File S1).

352

#### 353 Hops

354 The number of hops that observers performed did not depend on the prey type a demonstrator  
355 encountered (compared to initial cup presentation, demonstrator present \* prey type: estimate = -  
356  $1.375 \pm 0.951$ ,  $Z = -1.446$ ,  $p = 0.15$ ; cups after demonstrator playback \* prey type: estimate = -  
357  $0.636 \pm 1.015$ ,  $Z = -0.626$ ,  $p = 0.53$ ), so we removed these interactions from the final model. The  
358 final model shows that birds were hopping significantly more in the presence of a demonstrator  
359 compared to initial cup presentation (estimate =  $1.967 \pm 0.565$ ,  $Z = 3.482$ ,  $p < 0.001$ ; Fig. 3c), or  
360 to the cup presentation after a demonstrator (estimate =  $0.953 \pm 0.460$ ,  $Z = 2.071$ ,  $p = 0.04$ ). Again,  
361 the test order (estimate =  $0.135 \pm 0.452$ ,  $Z = 0.297$ ,  $p = 0.77$ ), or the association with a demonstrator  
362 (estimate =  $6.237 \pm 10.131$ ,  $Z = 0.616$ ,  $p = 0.54$ ) had no effect on an observer's behaviour and the  
363 variance estimates for random effects were small (variance for bird identity  $< 0.001$ ; variance for  
364 demonstrator video  $< 0.001$ ; Table 4 in File S1). One individual hopped considerably more than  
365 the others, but re-running analyses without it did not change the results. In particular, the increase  
366 in hopping in the presence of a demonstrator remained significant (hops during presence of a  
367 demonstrator versus initial cup presentation: estimate =  $1.653 \pm 0.415$ ,  $Z = 3.981$ ,  $p < 0.001$ ).

368

### 369 *Social information use*

370 Prey type in the video (estimate =  $0.372 \pm 0.814$ ,  $Z = 0.457$ ,  $p = 0.65$ ), the test order (estimate =  
371  $0.829 \pm 0.745$ ,  $Z = 1.113$ ,  $p = 0.27$ ), or the association score with a demonstrator (estimate = -  
372  $17.137 \pm 14.739$ ,  $Z = -1.163$ ,  $p = 0.25$ ) did not have a significant effect on an observer's cup choice  
373 but demonstrator video, included as a random effect, explained some of the observed variation  
374 (variance for bird identity = 0.031; variance for demonstrator video = 0.442; Table 5 in File S1).  
375 After observing a demonstrator discovering palatable prey in a coloured cup, only 10 birds landed

376 first on that cup, whereas 10 birds chose the alternative coloured cup (binomial test, 10/20  
377 compared to equal probability,  $p = 1$ ). Similarly, after video-playback of a demonstrator's response  
378 towards aversive prey, only 12 birds avoided the cup that the demonstrator fed from, whereas 9  
379 birds landed on it first (binomial test, 9/21 compared to equal probability,  $p = 0.66$ ). Only 5 birds  
380 matched our predictions in both tests, choosing the same cup colour as a demonstrator after  
381 receiving information about palatable prey, and avoiding that colour after seeing a demonstrator's  
382 disgust response. Again, this was not different from what would be expected if birds foraged  
383 randomly (binomial test, 5/20 compared to probability of 0.25,  $p = 1$ ).

384

385 Information in the video, however, did appear to affect the latency of observers' cup choice.  
386 Observers made their choice faster when they chose a cup matching the social information  
387 provided in the video (compared to birds that did not match our predictions, estimate =  $-0.837 \pm$   
388  $0.265$ ,  $Z = -3.154$ ,  $p = 0.002$ ; Fig. 4). This did not vary between the prey types observed (estimate  
389 =  $-0.024 \pm 0.262$ ,  $Z = -0.092$ ,  $p = 0.93$ ), or between the first and the second test (estimate =  $0.009$   
390  $\pm 0.226$ ,  $Z = 0.043$ ,  $p = 0.97$ ). Therefore, in both tests birds chose the cup faster when their decision  
391 matched a demonstrator's behaviour. The variance estimates for random effects were small  
392 (variance for bird identity = 0.167; variance for demonstrator video = 0.062; Table 6 in File S1).

393

## 394 **DISCUSSION**

395 Our experiment shows that blue tits, like many other species tested (e.g. McQuoid & Galef, 1993;  
396 Rieucou & Giraldeau, 2009; Zoratto et al., 2014) pay attention to video playback of a conspecific.  
397 Focal birds were more active in the presence of a demonstrator than when videos showed a cage  
398 without a conspecific present, and observers' behaviour differed depending on which prey type

399 was being sampled in the demonstration video. Furthermore, the identity of the demonstrator also  
400 explained some variation in observers' behaviour. Despite our predictions, however, we found that  
401 only half of the focal birds then chose to forage from the cup according to the information that  
402 demonstrators had provided, the same as if birds foraged randomly. Information from video  
403 playback, however, did influence how quickly birds made a choice: those that chose in accordance  
404 with the demonstrator did so more quickly. Together, these results suggest that social cues in video  
405 playback could provide blue tits with information about prey profitability, but the birds either did  
406 not acquire or chose not to use this social information in their decision-making.

407

408         Similar to previous studies, (Clark, 1970; Skelhorn, 2011), we found that demonstrators  
409 responded to aversive prey by performing beak wipes and headshakes. Head shaking and beak  
410 wiping has been proposed to provide observers with information about potentially toxic prey  
411 (Johnston, Burne & Rose, 1998; Skelhorn, 2011). This kind of 'disgust' behavior could increase  
412 the benefits for paying attention to a demonstrator, as encounters with aversive prey can elevate  
413 internal toxin levels (Skelhorn, Halpin & Rowe, 2016) or even increase the risk of mortality when  
414 prey are lethal (Longson & Joss, 2006). Perhaps this explains why we observed differences in focal  
415 birds' behavior between different video types, and why observers continued to pay more attention  
416 to a cup in an empty cage after observing a demonstrator encounter aversive prey. Alternatively,  
417 it is possible that focal birds faced the video screen and made more head turns when demonstrators  
418 discovered aversive prey simply because demonstrators were more active during this presentation.  
419 This could be investigated further by presenting focal birds videos that contain different cues but  
420 show similar amounts of activity.

421

422 Other research on social information use by blue tits also finds that use of social information  
423 is low: only approximately 50 % of individuals learn to solve a novel feeding task after observing  
424 a conspecific solve it (Sasvári, 1979; Aplin, Sheldon & Morand-Ferron, 2013). These studies differ  
425 from our experiment because in task solving tests, none of the individuals are expected to solve  
426 the task without demonstration or training; in our experiment, individuals had a 50 % probability  
427 to choose the predicted cup just by chance. Our result, that focal birds' foraging decisions do not  
428 differ from what would be expected if birds were choosing the cup randomly, is difficult to  
429 interpret. Individuals that chose the predicted cup in our experiment may have used social  
430 information, or may have just chosen by chance a cup that matched a demonstrator's behaviour.  
431 However, we found that individuals made their choice faster when choosing a cup that matched  
432 the information in the video. It has been suggested that one of the costs of personal information  
433 use is time and energy that individuals need for information gathering (Dall et al., 2005), and the  
434 observed time difference in our experiment indicates that the time cost to make a decision might  
435 be higher if individuals do not use social information. However, if we assume that all birds that  
436 chose the cup according to our predictions used social information because they made their choices  
437 more quickly, it is difficult to explain why all the other birds would have chosen an alternative  
438 cup, as we would expect their choices to be random. Alternatively, if we assume that none of the  
439 birds used social information from the videos, it is difficult to explain the observed difference in  
440 their decision times.

441

442 One possibility is that some of the focal birds used the cues from videos differently than  
443 others. For example, neophobia or competition could have affected observers' foraging choices  
444 (Gibelli & Dubois, 2016). After seeing a demonstrator eating palatable prey from a coloured cup,

445 some observers might interpret that cup to be empty and therefore choose an alternative cup to  
446 avoid competition. On the other hand, observers might interpret the video of a cup in an empty  
447 cage so that demonstrators did not want to forage from that cup. Individuals might therefore choose  
448 the same cup as a demonstrator just to avoid novelty, even after seeing a demonstrator eating  
449 aversive prey. Furthermore, birds were pre-trained to locate favourable prey items from food cups,  
450 albeit of different colour, so instead of using social information about food unpalatability, they  
451 might have relied on their previous experience with prey (e.g. Kendal, Coolen & Laland, 2004).  
452 In addition, individuals might have had preferences for different cup colours, but we did not find  
453 that they chose any of the coloured cups more often than others, and the cup colours for  
454 demonstrator and control videos were randomized.

455

456 It has been suggested that individuals are more likely to rely on social information when the  
457 costs to acquire personal information increase (Kendal, Coolen & Laland, 2004; Kendal et al.,  
458 2005), and it is possible that in our experiment the cost of foraging from the “wrong” cup was too  
459 low to detect information use. In addition, some characteristics of observers such as sex and age  
460 (Loukola, Seppänen & Forsman, 2012; Aplin, Sheldon & Morand-Ferron, 2013, Guillette &  
461 Healy, 2014), personality (Marchetti & Drent, 2000), or dominance status (Nicol & Pope, 1999),  
462 could have made it more difficult for us to detect an effect of social information on cup choice. In  
463 a previous study of social learning in blue tits, for example, juvenile females were almost twice as  
464 likely to learn the novel foraging task than other age/sex classes, and only 37.5% of adults overall  
465 learned by observing others (Aplin, Sheldon & Morand-Ferron, 2013). In our study, all observers  
466 were adult birds and we do not know their sex. Future work should therefore present blue tits with  
467 more complicated tests with higher foraging costs (e.g. Aplin, Sheldon & Morand-Ferron, 2013),

468 and ensure sex and age are known. Still, in our experiment only five birds made their choice in  
469 accordance with the demonstrator in both tests, so individuals were not consistent in their  
470 information use and it is therefore unlikely that their sex would explain the observed variation.  
471 The variation in information use between the two tests, however, is not surprising, as individuals  
472 might value different type of social information differently. For instance, individuals' current toxin  
473 levels and energetic state might influence their decision to attack aversive prey (Skelhorn, Halpin  
474 & Rowe, 2016), and also increase the value of social information about prey unpalatability.

475

476 To further investigate the effectiveness of video playback in Parid tits, it could be useful to  
477 compare focal birds' responses to videos to their response to live demonstrators. This, however,  
478 would be difficult to conduct as live demonstrators vary in when and how they perform behaviours.  
479 For example, individuals' propensity to eat aversive prey could depend on intrinsic differences,  
480 such as their current energetic state (Skelhorn, Halpin & Rowe, 2016) that might vary over time.  
481 In our experiment, the time that demonstrators spent eating aversive prey differed considerably  
482 among individuals, and some of the demonstrators showed a stronger disgust response (more beak  
483 wipes and head shakes) than others. With video playback, we could present focal birds  
484 standardized videos of demonstrators' responses but the use of live demonstrators would include  
485 much more variation, and therefore require a high number of individuals to be tested. A second  
486 potential problem with our experiment was that vocal communication between observer and  
487 demonstrator was impossible. However, we did not hear any of the focal birds vocalize during  
488 playback, nor did any of the demonstrators vocalize during filming. We therefore suggest that our  
489 results of focal birds' behavioural changes during video playback, the different responses  
490 depending on demonstrator identity, and the effect we detected on the latency to forage, provide

491 adequate evidence that blue tits pay attention to video playback. We assert that this could be a  
492 valid method for studying social information use.

493

#### 494 **Conclusion**

495 In conclusion, our study showed that blue tits respond to video playback of a conspecific,  
496 and that individuals paid more attention to demonstrators encountering aversive prey. This  
497 indicates that they did not only respond to the presence of a demonstrator but also observed  
498 differences in a demonstrator's behaviour. The cues from videos then influenced focal birds'  
499 behaviour in a foraging task, as individuals that chose to forage in accordance with a demonstrator  
500 made their foraging choice faster. The proportion of birds that made their choice according to  
501 information from videos, however, did not differ from random, and we are therefore unable to  
502 explain the differences in these two measures of foraging. Together, our results suggest that video  
503 playback of a conspecific can provide social cues to blue tits, and video playback therefore  
504 provides a promising method for studying social behaviour and learning in Parid tits, with potential  
505 application for studies in both captivity and the wild. However, we do not know how these social  
506 cues are later used in decision-making, and this seems to vary greatly among individuals.

507

#### 508 **Acknowledgements**

509 We are grateful to Maggie Dinsdale, Sam Melvin and Sarah Manley for taking care of the birds,  
510 Ian Millar for helping to build experimental facilities and Karen Spencer for Home Office support.  
511 We also thank Neeltje Boogert and Rebecca Kilner for helpful comments on the study and  
512 manuscript.

# Figure 1

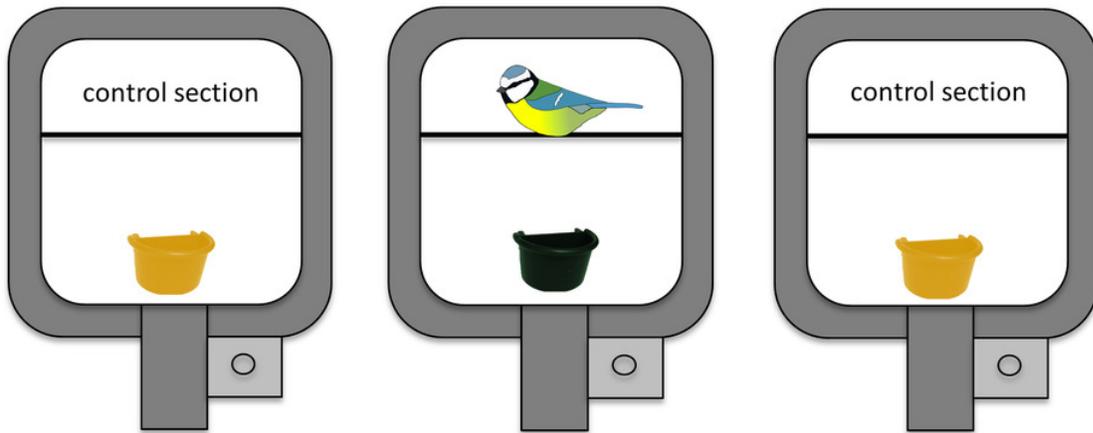

The experimental set-up.

a) The view of the test cage (a computer monitor and a camera recording focal birds' behaviours were placed against a plexiglass wall of the cage), b) presentation of video playback including a demonstrator discovering prey from a coloured feeding cup (45 seconds) and two control sections of a different coloured cup (30 seconds before and 30 seconds after a demonstrator), c) social information use test, where focal birds had a choice to forage from the same cup as the demonstrator, or from the cup in the control video.

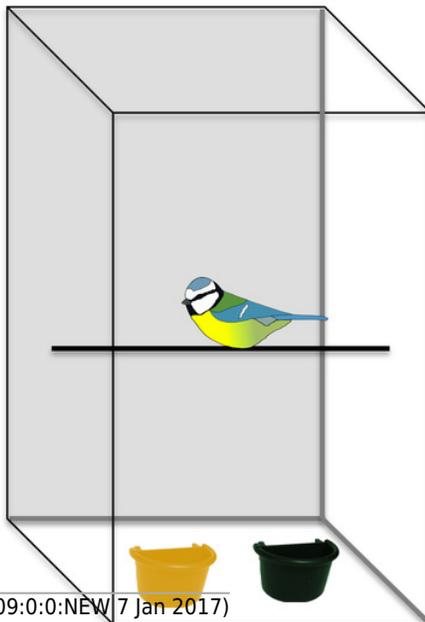

a)

b)

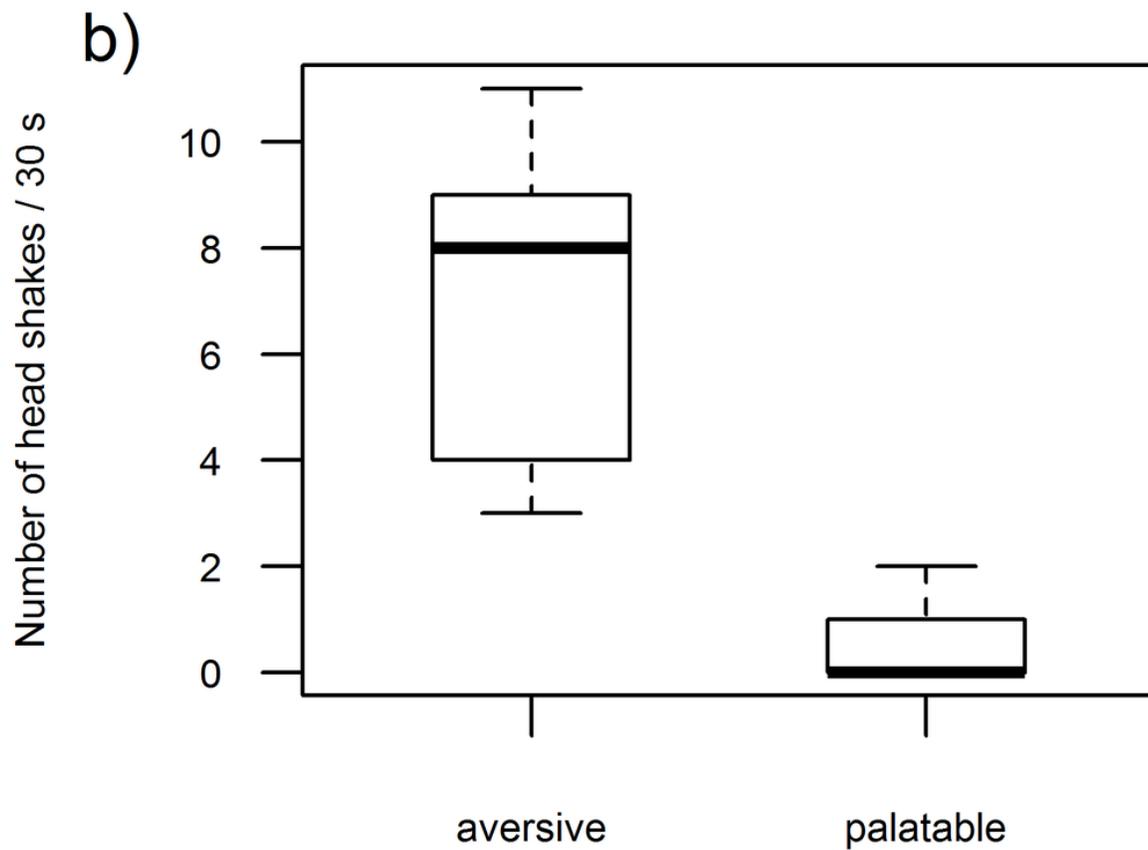

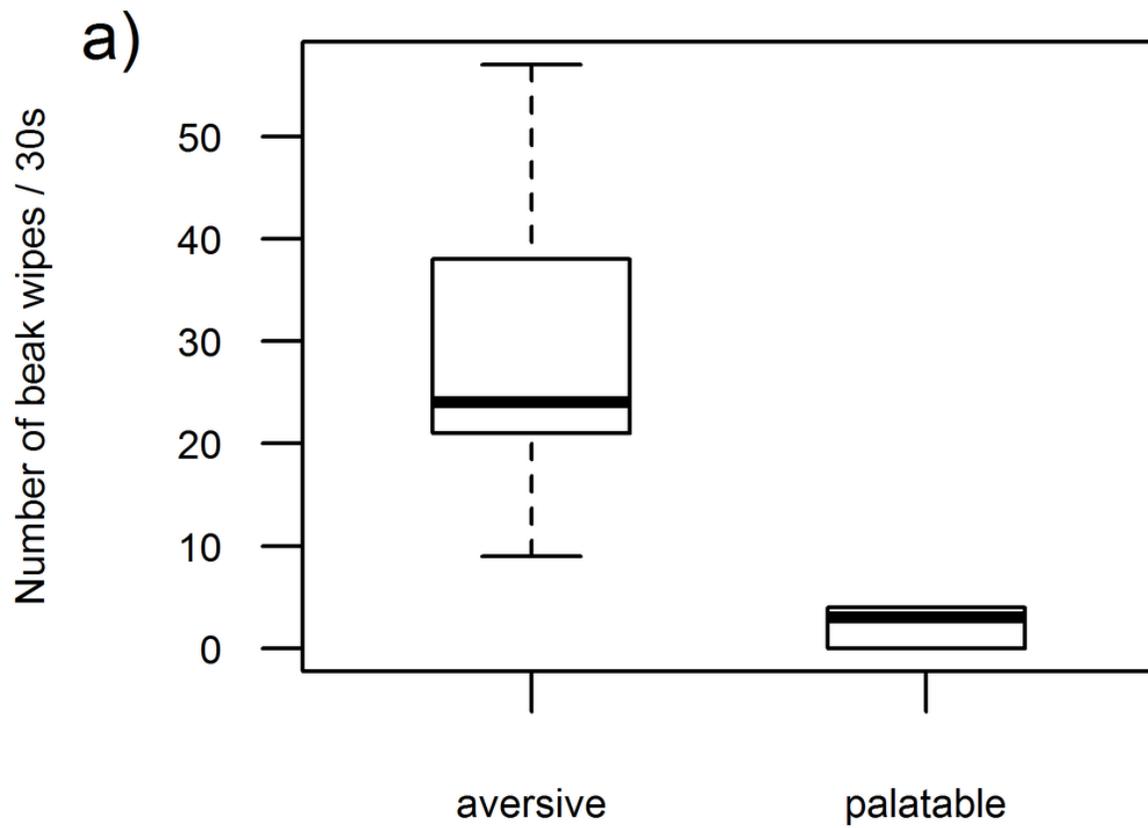

c)

## Figure 2

Demonstrators' response.

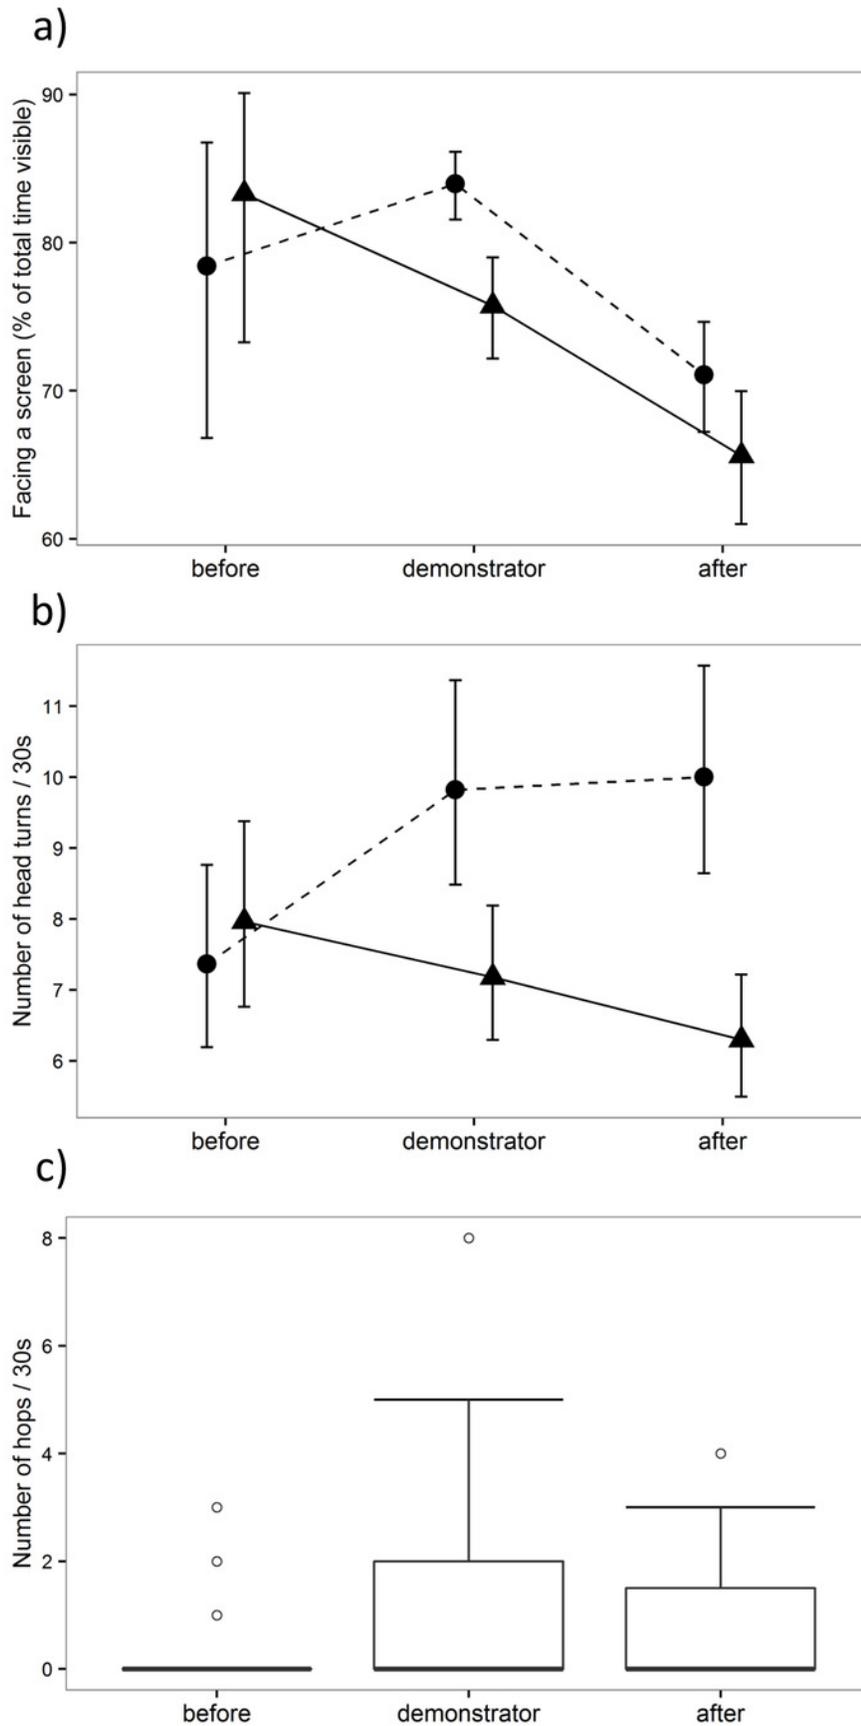

The number of beak wipes (a) and headshakes (b) demonstrators ( $n = 6$ ) performed when encountering aversive or palatable prey.

## Figure 3

Focal birds' response to video playback.

Mean ( $\pm$  s.e.) proportion of time observers faced the screen (a), and the number of head turns (b) and hops (c) observers performed when they were presented i) an empty cage with a feeding cup before a demonstrator, ii) a demonstrator or iii) an empty cage with a feeding cup after a demonstrator. The time observers faced the screen, and the number of head turns differed between palatable (triangles + solid line) and aversive prey (circles + dashed line).

## Figure 4

Time before individuals chose a cup in a two-choice test.

Time (sec) before individuals made their cup choice when they i) chose a different cup than predicted (i.e. did not use social information,  $n = 19$ ), or ii) chose the predicted cup ( $n = 21$ ). The interaction between prey type and social information use did not have a significant effect on time that it took birds to choose a cup (estimate =  $0.218 \pm 0.532$ ,  $Z = 0.410$ ,  $p = 0.68$ ) so responses are plotted across prey types.
