**Background.** The experience of ‘sensed presence’ – a feeling or sense that another entity, individual or being is present despite no clear sensory or perceptual evidence – is known to occur in the general population, appears more frequently in religious or spiritual contexts, and seems to be prominent in certain psychiatric or neurological conditions and may reflect specific functions of social cognition or body-image representation systems in the brain. Previous research has relied on ad-hoc measures of the experience and no specific psychometric scale to measure the experiences exists to date.

**Methods.** Based on the phenomenological description in the literature, we created the 16-item Sensed Presence Questionnaire (SenPQ). We recruited participants from i) a general population sample, and; ii) a sample including specific selection for religious affiliation, to complete the SenPQ and additional measures of well-being, schizotypy, social anxiety, social imagery and spiritual experience. We completed an analysis to test internal reliability, the ability of the SenPQ to distinguish between religious and non-religious participants, and whether the SenPQ was specifically related to positive schizotypal experiences and social imagery. A factor analysis was also conducted to examine underlying latent variables.

**Results.** The SenPQ was found to be reliable and valid, with religious participants significantly endorsing more items than non-religious participants and the scale showing a selective relationship with construct relevant measures. Principal components analysis indicates two underlying factors interpreted as reflecting ‘benign’ and a ‘malign’ sensed presence experiences.

**Discussion.** The SenPQ appears to be a reliable and valid measure of sensed presence experience although further validation in neurological and psychiatric conditions is warranted.

## Abstract

**Background.** The experience of ‘sensed presence’ – a feeling or sense that another entity, individual or being is present despite no clear sensory or perceptual evidence – is known to occur in the general population, appears more frequently in religious or spiritual contexts, and seems to be prominent in certain psychiatric or neurological conditions and may reflect specific functions of social cognition or body-image representation systems in the brain. Previous research has relied on ad-hoc measures of the experience and no specific psychometric scale to measure the experiences exists to date.

**Methods.** Based on phenomenological description in the literature, we created the 16-item Sensed Presence Questionnaire (SenPQ). We recruited participants from i) a general population sample, and; ii) a sample including specific selection for religious affiliation, to complete the SenPQ and additional measures of well-being, schizotypy, social anxiety, social imagery and spiritual experience. We completed an analysis to test internal reliability, the ability of the SenPQ to distinguish between religious and non-religious participants, and whether the SenPQ was specifically related to positive schizotypal experiences and social imagery. A factor analysis was also conducted to examine underlying latent variables.

**Results.** The SenPQ was found to be reliable and valid, with religious participants significantly endorsing more items than non-religious participants and the scale showing a selective relationship with construct relevant measures. Principal components analysis indicates two underlying factors interpreted as reflecting ‘benign’ and a ‘malign’ sensed presence experiences.

**Discussion.** The SenPQ appears to be a reliable and valid measure of sensed presence experience although further validation in neurological and psychiatric conditions in warranted.

48 **Introduction**

49 William James (1902) first attempted to understand the sensed presence experience  
50 psychologically, describing the experience “as if there were in the human consciousness a  
51 sense of reality, a feeling of objective presence, a perception of what we may call ‘something  
52 there’”. The philosopher and psychiatrist Karl Jaspers also discussed it in his influential book  
53 on the phenomenology of psychiatry, *General Psychopathology*, defining it as where “we are  
54 aware that something is present which at that moment is not based on any obvious sensory  
55 sign” (Jaspers, 1913 / 1963).

56

57 Contemporary researchers define the experience of sensed presence, sometimes called  
58 ‘feeling of presence’ or ‘felt presence,’ as the subjective experience of the presence of an  
59 external entity, being, or individual despite no clear sensory or perceptual evidence  
60 (Thompson, 1982; Cheyne, 2001; Blom, 2010; Luhrmann, 2012, 2013; Alderson-Day, 2016).  
61 This more recent research has reported that it is particularly prevalent in certain contexts and  
62 psychological states.

63

64 One area particularly associated with the sensed presence experience is spirituality and  
65 religion. Luhrmann and Morgain (2012) described how participants in a prayer group  
66 frequently described the experience of a ‘near tangible presence’, and Luhrmann’s  
67 ethnographic work (summarised in Luhrmann, 2012) has noted how this experience forms an  
68 essential component of evangelical religious practice. Suedfeld and Mocellin (1987)  
69 described the role of intense physiological states in ‘spirit quests’ common in many  
70 traditional religious practices that specifically induce a sensed presence experience, and  
71 Granqvist et al. (2005) and Granqvist and Larsson (2006) have demonstrated experimentally  
72 that the experience can be induced by priming participants with religious concepts.

73

74 However, the experience has also been reported in a range of other, neurophysiological  
75 contexts. These include sleep-related hallucinations and paralysis, where it is typically  
76 associated with fear and anxiety (Cheyne et al., 1999), epileptic seizure (Landtblom, 2006)  
77 and particularly temporal lobe epilepsy (Trimble & Freeman, 2006), psychoactive drug use  
78 (Barbosa et al., 2005) and direct brain stimulation (Arzy & Schurr, 2016); and has been  
79 associated with psychosis and auditory hallucinations (Woods et al., 2015), acquired brain  
80 injury (Brugger et al., 1996), Parkinson's disease (Fenelon et al., 2011) and a range of intense  
81 emotional or physiological states (Suedfeld & Mocellin, 1987) including bereavement  
82 (Steffan & Coyle, 2011).

83

84 Previous theories have suggested the sensed presence phenomenon may be a result of a  
85 projected internal body map (Brugger et al., 1996), partial activation of the threat system  
86 (Cheyne & Girard, 2007), or a form of externalised social imagery (Nielsen, 2007;  
87 Solomonova et al., 2008), or, perhaps more exotically, an external projection of autonomous  
88 unconscious processes (Jaynes, 2000; Jung, 1969).

89

90 Notably, neuropsychological theories have been based on increasing numbers of studies  
91 where the experience has been induced in the lab, or reported in observational or patient  
92 studies, but it is noteworthy that no specific psychometric measure for the sensed presence  
93 experience exists and current studies rely on scales which are not ideally suited to the task or  
94 simple verbal description.

95

96 A seven item subscale of the Other Experiences Questionnaire (OEQ7) (Nielsen, cited in  
97 Solomonova et al., 2008), has been used to measure experiences akin to sensed presence

98 experience in previous studies (Solomonova et al., 2008). However, the OEQ7 is actually  
99 intended to measure ‘social imagery’, and includes items on imaginary companions, seeing  
100 apparitions and the feeling of being followed, alongside items on the actual sensed presence  
101 experience.

102

103 Trimble and Freeman (2006) measured sensed presence in religious and non-religious  
104 individuals with epilepsy by using items from the Index of Core Spiritual Experiences  
105 (INSPIRIT) questionnaire (Kass et al., 1991). However, as the study used selected items from  
106 a specific spirituality questionnaire, this would not be suitable for measuring sensed presence  
107 experiences in other contexts.

108

109 Other scales include the sensed presence experience but only as a single item – such as the  
110 Tellegen Absorption Scale (Tellegen and Atkinson, 1974), the Magical Ideation Scale  
111 (Eckblad and Chapman, 1983), and the Cardiff Anomalous Perceptions Scale (Bell et al.,  
112 2006).

113

114 Alternatively some studies have simply asked people to affirm whether they have had a  
115 sensed presence experience. For example, while Hay (1979) reported useful descriptive  
116 themes of SP experiences from participants, Hay (1979) and Hay & Morisy (1978) did not  
117 use comprehensive or validated measures to capture SP experiences and simply relied on a  
118 single question.

119

120 Given the potential for sensed presence experiences to provide a window into  
121 neuropsychological mechanisms for body representation or social cognition, clearly, a robust  
122 and validated measure of the phenomena is needed.

123 With this in mind, we created and investigated the reliability and validity of a new scale,  
124 called the ‘Sensed Presence Questionnaire’ (SenPQ), designed to capture the experience of  
125 ‘sensed presence’ in a psychometrically robust manner.

126

127 As religious practice has been traditionally associated with greater levels of sensed presence  
128 experience, as part of the scale validation we predicted that individuals who have religious  
129 practice / belief from the general population would score higher on the SenPQ as people  
130 without. Based on previous research, we also predicted that the SenPQ would selectively  
131 correlate with measures of unusual perceptual experiences but no other aspects of schizotypy,  
132 as well as correlating with measures of social imagery and daily spiritual experience.

133

#### 134 **Materials and Methods**

135 A cross-sectional observational design was used in the general population. Data was collected  
136 in the form of an online survey using two distinct samples. The study was reviewed and  
137 ethically approved by the UCL ethics review board (ref no.: 8587/001). Participants indicated  
138 consent on the online form.

139

#### 140 *Design of the Sensed Presence Questionnaire (SenPQ)*

141 The Sensed Presence Questionnaire (SenPQ) comprises of 16 questions. These were derived  
142 from a literature review of the sensed presence phenomenon spanning studies from sleep  
143 paralysis, epilepsy and other neurological disorders, psychosis, stress and anxiety, ritual, drug  
144 induced experiences, and the general population. As well as covering a range of typical  
145 sensed presence experiences from the scientific literature, the scale also includes items that  
146 are positively and negatively valenced, as well as neutrally valenced in their presentation.

147

148 The questionnaire requests that respondents refer to experiences from the last month only  
149 when rating the items, and not to record any experiences associated with drug-induced  
150 experiences. Respondents are asked to indicate the frequency with which the experience has  
151 occurred using a Likert-like scale: ‘Never’, ‘Occasionally’, ‘Sometimes’, ‘Very Often’,  
152 ‘Always’. The questionnaire is freely available online and has been released under a Creative  
153 Commons license at the following link: <https://osf.io/fecgz/>

154

### 155 *Participants*

156 Participants were recruited via two methods: i) online via the <http://proflific.ac> online study  
157 recruitment platform that has diverse participant base and where we received 101 completed  
158 responses from separate individuals (Sample S1) from 135 responses in total including  
159 incomplete data sets. In addition, social media advertisements were sent from the authors’  
160 personal accounts and accounts associated with the authors’ university department (with  
161 notices that did not refer to anything spiritual or religious) and emails were sent to religious  
162 groups including university religious societies (Hindu society, Islamic Society, Christian  
163 Union, Sikh Society, Buddhist Society, and the Jewish Society) and local churches requesting  
164 participants (Sample S2). Recruitment for both samples was started in parallel. The  
165 questionnaire took approximately 25 minutes to complete. Participants recruited via the  
166 online recruitment service were paid £4 upon questionnaire completion. All participants were  
167 directed to the same online questionnaires.

168

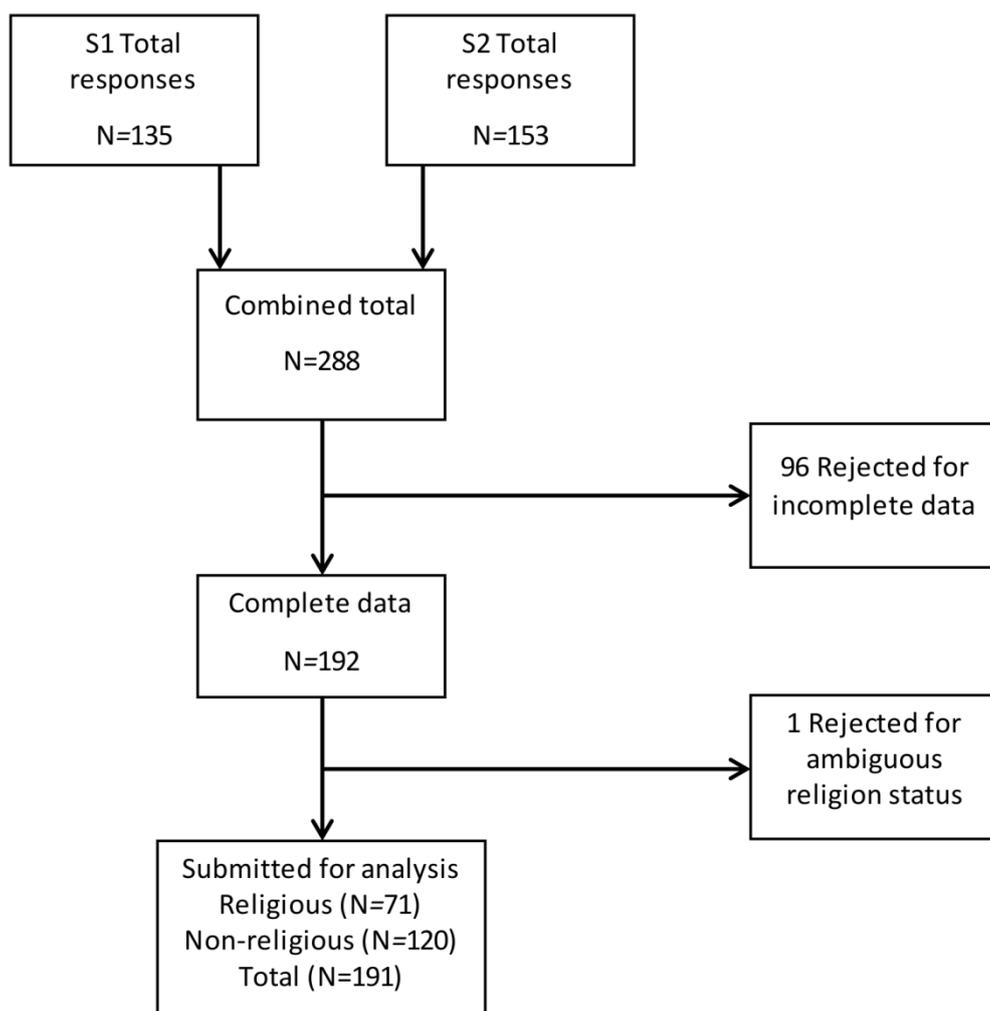

169 Individuals who clicked on the link to the survey and began to fill in the survey were  
170 considered to have been recruited into the study, regardless of whether the scales were fully  
171 completed although only complete questionnaire sets were entered into the analysis.

172 Questionnaires were preceded by a page requesting demographic data that required age,  
173 gender, religious belief, average meditation practice, ethnic group, and education level.

174

175 Both samples were combined for the final analysis which consisted of a total of 191  
176 participants included (see Figure 1). Analysis scripts that conduct a separate analysis for each  
177 sample (minus the principal components analysis which is underpowered when not conducted  
178 on the whole sample) are available on the Open Science Framework page for this study  
179 (<https://osf.io/fecgz/>), which demonstrate the same pattern of results in each sample,  
180 supporting the reliability and validity of the scale.

181

182

183

**Figure 1 - Recruitment diagram**

184

*Additional Measures*

185 Other Experiences Questionnaire (OEQ7) (Solomonova et al., 2008): a validated measure  
186 demonstrated to capture social imagery, and has previously been tested in context of sleep  
187 paralysis and anxiety.  
188

189

190 WHO-5 (World Health Organisation, 1998): a short form, validated well-being questionnaire,  
191 demonstrated to capture well-being as accurately as its extended version.

192 Brief Oxford-Liverpool Inventory of Feeling and Experiences (O-LIFE) (Mason et al., 2005):  
193 a short form validated scale to measure schizotypal personality traits, developed from a larger  
194 version (Claridge et al., 1996), including subscales for unusual experiences (UE), cognitive  
195 disorganisation (CD), introvertive anhedonia (IA), and impulsive non-conformity (IN).

196

197 Daily Spiritual Experience Scale (DSES) (Underwood & Teresi, 2002): a validated scale  
198 designed to assess ordinary and daily connection with the transcendent in daily life. Question  
199 16 was omitted in our version as the rest of the 15 items all coded in the same format, and has  
200 been omitted and validated in absence in previous studies (Ellison & Fan, 2008).

201

202 The Social Interaction Anxiety Scale (SIAS) (Mattick & Clarke, 1998): a validated scale  
203 designed to capture social interaction anxiety.

204

205 Participants were also given the option of a free text box at the end of the questionnaire series  
206 to describe a sensed presence experience, if they indicated they had experienced one.

207

208 *Analysis*

209 Internal reliability of the SenPQ was tested with Cronbach's Alpha (Cronbach, 1951).

210 Validity was determined firstly by whether SenPQ score distinguished between religious and  
211 non-religious groups by using an independent samples t-test, predicting a significant  
212 difference between SenPQ in religious and non-religious groups. Secondly we examined the  
213 association between SenPQ score and additional measures, predicting that the SenPQ would  
214 selectively correlate with the O-LIFE unusual experiences subscale, the OEQ7 measure of  
215 social imagery and the DSES measure of spiritual experience.

216

217 In addition, we completed a principal components analysis of the SenPQ items on the entire  
218 sample using direct oblimin rotation based on the assumption that underlying factors would  
219 not be independent. The mean item scores for each individual factor loading were used for all  
220 subsequent analysis. Parallel analysis for principle components (95% confidence interval,  
221 1000 random correlation matrices) (Horn, 1965; O'Connor, 2000) and observation of the  
222 scree plot (Cattell, 1966) were used to select retained factors.

223

224 We also completed a receiver operating characteristic (ROC) analysis to examine how scale  
225 specific scale scores distinguished between religious and non-religious groups.

226

## 227 **Results**

### 228 *Demographics*

229 The total sample consisted of 89 males, 99 females, 2 who selected 'Other' and 1 who  
230 selected 'Prefer not to say'. The mean age of the sample was 36.23 (SD = 13.4; Range 17 –  
231 73). Religious affiliation, ethnicity and level of education are reported in Table 1. For the  
232 purposes of classifying people into religious and non-religious groups for further analysis,  
233 people who selected 'No Religion' or 'Agnostic' were considered non-religious, as were  
234 individuals who recorded themselves as 'Atheist' under the 'Other' option. All others were  
235 considered religious.

236

237

	<i>Frequency (%)</i>
<b>Religious Affiliation</b>	
No Religion	99 (51.83)
Agnostic	16 (8.37)
Christian	45 (23.56)
Buddhist	4 (2.09)
Hindu	2 (1.04)
Jewish	3 (1.57)
Muslim	3 (1.57)
Sikh	3 (1.57)
Other	16 (8.37)
<b>Highest Level of Education</b>	
GCSE	10 (5.23)
A Level	29 (15.18)
University Undergraduate	93 (48.69)
University Postgraduate	59 (30.89)

238

### 239 **Table 1 - Religion and education of sample**

240

241 20 participants reported daily meditation practice, 10 weekly practice, 23 monthly practice,  
 242 and 138 no practice. Self-reported ethnicity of the sample was “English / Welsh / Scottish /  
 243 Northern Irish / British” (N=131), “White other” (N=25), “Indian” (N=8), “White and Asian”  
 244 (N=5), “Chinese” (N=4), “White and Black African” (N=3), “Pakistani” (N=2), “Other”  
 245 (N=2), “Irish” (N=2), “White and Black Caribbean” (N=2), “Other Mixed / Multiple ethnic  
 246 background” (N=2), “Bangladeshi” (N=1), “African” (N=1), “Caribbean” (N=1), “Arab”  
 247 (N=1), “Gypsy or Irish Traveller” (N=1).

248

### 249 *Statistical analysis*

250 Due to the sampling distribution of mean scores on the SenPQ violating the assumption of  
 251 normal distribution, all analyses were conducting using a simple bootstrap re-sampling  
 252 method (1000 samples, 95% CI) (Bland & Altman, 2015). All data analysis used SPSS v.22

253 (SPSS Inc). The raw data and analysis scripts for this study are freely available online at the  
254 Open Science Framework at the following link: <https://osf.io/fecgz/>

255

### 256 *Internal reliability*

257 All SenPQ items were entered into internal reliability analysis and the scale demonstrated  
258 very high internal consistency (Cronbach's alpha = 0.951).

259

### 260 *Validity*

261 Means and standard deviations for the scale scores are displayed in Table 2. Discriminant  
262 validity of the SenPQ was demonstrated by conducting an independent samples t-test (two-  
263 tailed) between mean scores from religious (N = 71) and non-religious groups (N = 120). The  
264 religious group had a higher mean score than the non-religious group (see Table 2), a  
265 difference which was significant when tested with an independent samples t-test ( $t = -3.592$ ,  
266  $p = 0.002$ , mean difference = -5.208, 95% CI: -8.098 - -2.156; Cohen's  $d = 0.51$ ), indicating  
267 good discriminant validity.

268

269 As can be seen in Table 3, the SenPQ demonstrated a strong significant correlation with the  
270 OEQ-7 social imagery scale and a moderate significant correlation with the DSES daily  
271 spiritual experiences scale. There was a strong significant correlation with the unusual  
272 experiences subscale of the O-LIFE schizotypy scale, a weak correlation with the impulsive  
273 non-conformity subscale, and no significant correlation with the cognitive disorganisation or  
274 introvertive anhedonia subscales, indicating a good convergent and divergent validity.

275

276

<i>Group</i>	<i>N</i>	<i>Age</i>	<i>Gender</i>			<i>O-LIFE</i>					<i>DSES</i>	<i>WHO-5</i>	<i>SIAS</i>
			<i>(M:F:O)</i>	<i>SenPQ</i>	<i>OEQ7</i>	<i>Total</i>	<i>UE</i>	<i>CD</i>	<i>IA</i>	<i>IN</i>

285

286 **Table 3 - Pearson correlations between SenPQ and other scales in the total sample.**

287

288 Legend: SenPQ=Sensed Presence Questionnaire, O-LIFE = brief Oxford-Liverpool Inventory of Feelings and Experiences, UE = O-LIFE Unusual  
 289 Experiences subscale, CD = O-LIFE Cognitive Disorganisation subscale, IA = O-LIFE Introvertive Anhedonia subscale, O-LIFE IN = Impulsive Non-  
 290 Conformity subscale, OEQ-7 = Other Experiences Questionnaire, WHO-5 =World Health Organisation 5-item well-being questionnaire, DSES = Daily  
 291 Spiritual Experience Scale, SIAS = Social Interaction Anxiety Scale. \*\*\*p<0.001.

292

293 *Measures of anxiety and well-being*

294 No significant associations were found between the SenPQ and WHO-5 score ( $r = .56$ ,  $p =$   
295  $.443$ ) and between the SenPQ and SIAS score ( $r = .025$ ,  $p = .773$ ).

296

297 *Factor analysis of the SenPQ*

298 To investigate the factor loadings of the Sensed Presence Questionnaire, a factor analysis was  
299 run on all 16 items.

300

301 To test all assumptions, a Kaiser–Meyer–Olkin measure of sampling adequacy (0.925) and  
302 Bartlett’s test of sphericity [ $\chi^2 (120) = 2467.009$ ,  $p < 0.001$ ] were run and considered  
303 adequate, with all items significantly correlating by at least 0.3 ( $p < 0.001$ ).

304

305 A two factor solution was selected based on parallel analysis for principal components (Horn,  
306 1965; O’Connor, 2000) and inspection of the scree plot (Cattell, 1966). The first component  
307 explained 52.28% of the variance, and the second component explained an additional 7.66%  
308 of the variance in the sample.

309

310 The pattern matrix can be found in Table 4. Factor one was interpreted as ‘Benign Presence’  
311 and factor two was interpreted as ‘Malign Presence’.

312

313

	<i>Item</i>	<i>Factor 1</i>	<i>Factor 2</i>
13	I have felt the presence of a protective being around me that I couldn't see	0.990	
6	I have felt I was being watched over by caring being that I couldn't see	0.981	
3	When I was under a lot of pressure, I felt someone or something was accompanying me	0.823	
8	I have felt when an unseen presence has arrived	0.707	
5	During times of stress I have had the feeling that I was being accompanied by an unseen presence	0.604	
11	I have visited certain places where I can feel the presence of distinct but unseen beings	0.581	
12	I can feel the presence of people that I know are physically distant from me	0.559	
15	Even though I knew the person had died, I felt them accompanying me	0.550	
7	When I have visited specific locations, I felt I was in the presence of an unseen being or beings	0.494	0.432
1	I have felt another being or beings near me when I couldn't see anyone around me that could explain it		0.544
10	I have felt as if someone or something is near me, even though I know it is not really the case		0.578
2	When half asleep I have thought someone else was with me, only to find out when I woke up that they couldn't have been		0.693
16	Even though I knew it was my imagination, I still felt as if someone or something was with me		0.701
9	I have woken up during the night with the feeling that an unseen presence was in the room with me		0.702
14	I have felt a sinister or threatening presence around me, despite not being able to see any evidence for it		0.822
4	I have had the feeling that a negative or hurtful presence was around me that I couldn't see		0.896

 317 **analysis of item scores from 191 samples.**

318

319 Legend: All loadings less than 0.4 are not displayed.

320 *ROC Analysis*

321 Data from the psychometric measures was entered into a ROC analysis to show they  
 322 discriminated religious from non-religious groups over the extent of their score range. Results  
 323 are displayed in Table 5 and Figure 2.

324

<i>Measure</i>	<i>Area Under the Curve</i>	<i>Std. Error</i>	<i>95% CIs</i>	
<i>SenPQ</i>	.655***	.041	.575	.735
<i>UE</i>	.592*	.042	.509	.675
<i>CD</i>	.462	.043	.379	.546
<i>IA</i>	.458	.042	.376	.540
<i>IN</i>	.473	.043	.390	.556
<i>O-LIFE</i>	.490	.043	.406	.574

 327 **(positive) or non-religious (negative) identification.**

328

329 Legend: SenPQ=Sensed Presence Questionnaire, O-LIFE = brief Oxford-Liverpool Inventory of  
 330 Feelings and Experiences, UE = Unusual Experiences O-LIFE subscale, CD = Cognitive  
 331 Disorganisation O-LIFE subscale, IA = Introvertive Anhedonia O-LIFE subscale, IN = Impulsive  
 332 Non-Conformity O-LIFE subscale, OEQ-7 = Other Experiences Questionnaire, WHO-5 = World  
 333 Health Organisation 5-item well-being questionnaire, DSES = Daily Spiritual Experience Scale, SIAS  
 334 = Social Interaction Anxiety Scale. Asymptotic significance: \* $p < 0.05$ , \*\*\* $p < 0.001$ .

335

336

337 **Figure 2 - Graph of receiver operating characteristic (ROC) curve for DSES, OEQ7, UE,**  
 338 **and SenPQ compared to the null reference in classifying religious and non-religious**  
 339 **participants.**

340

341 Legend: SenPQ=Sensed Presence Questionnaire, DSES = Daily Spiritual Experience Scale, OEQ-7 =  
 342 Other Experiences Questionnaire, UE = Unusual Experiences O-LIFE subscale.

343

344 The most efficient total discriminator of religious and non-religious groups was the DSES  
 345 daily spiritual experience scale. The SenPQ and OEQ-7 Other Experiences Questionnaire  
 346 were highly discriminant and perform almost identically. The Unusual Experiences subscale  
 347 of the O-LIFE schizotypy scale discriminates between groups to a lesser extent and all other  
 348 scale show no significant discriminant ability.

349

350 **Discussion**

351 This study involved the creation and initial validation of a 16-item sensed presence  
352 questionnaire and in a general population sample we demonstrated that the SenPQ is a  
353 reliable and valid measure for measure the experience of 'sensed presence'.

354

355 One of the clearest findings is that the experience of 'sensed presence' is quite common in the  
356 general population, even among those who profess no religious belief. The experience was  
357 more commonly reported in people who either classify themselves as having a specific  
358 religion or who score more highly on a measure of daily spiritual experience, as was  
359 predicted from previous research (Luhrmann and Morgain, 2012; Luhrmann, 2012; Granqvist  
360 et al., 2005; Granqvist and Larsson, 2006).

361

362 However, considering that the experience of sensed presence has been reported in the context  
363 of various states and conditions outside of a religious framework, including sleep disorders,  
364 neurological conditions, drug use, and intense physiological and emotional stress, we would  
365 expect that the Sensed Presence Questionnaire to be useful across a range of presentations  
366 and this needs to be a focus for future validation studies.

367

368 A particularly notable finding from the principal components analysis was the emergence of  
369 distinct factors for 'benign' and 'malign' sensed presence experiences, echoing reports from  
370 the literature on differing emotional valence of sensed presence experiences (Alderson-Day,  
371 2016). However, as this study specifically invited people with religious or spiritual beliefs to  
372 participate, and didn't specifically seek to include people with medical conditions associated  
373 with sensed presence experiences, it is likely that benign experiences may be more common  
374 in this sample and therefore potentially more likely to present as a distinct factor within the

375 population. Future work will need to examine how well the benign / malign distinction holds  
376 up in other populations and samples.

377

378 In terms of limitations, as an initial validation study, additional data is needed to test whether  
379 the scale remains reliable and valid in further samples and more diverse populations. We used  
380 two sampling methods; one that drew participants from an online service that specifically  
381 recruits a diverse participant base to participate in online studies, the second was a  
382 combination of non-targeted recruitment using social media and specific invitations to  
383 religious groups. Although our sample was broadly representative of the religious, ethnic and  
384 age groups in the general population of the UK, it over-sampled people with higher levels of  
385 education. Considering this, further validation needs to be conducted using additional formats  
386 and a more representative general population sample.

387

### 388 *Conclusions*

389 From the data presented here, the Sensed Presence Questionnaire (SenPQ) appears a reliable  
390 and valid measure of the 'sensed presence' experience. A principal components analysis  
391 suggests that the SenPQ may comprise of two factors, malign and benign presence. We hope  
392 the scale will be subject to further validation studies and will allow the 'sensed presence'  
393 experience to be investigated in a range of conditions.
