Abstract

We report the genome sequence of *Exiguobacterium pavilionensis* str. N139, isolated from a high-altitude Andean lake. The 2,952,588-bp genome contains one chromosome and three megaplasms. The genome analysis suggests the presence of enzymes that confer *E. pavilionensis* str. N139 the ability to grow under multiple environmental extreme conditions, including high concentrations of different metals and high ultraviolet B radiation. Moreover, the regulation of its tryptophan biosynthesis suggests that novel pathways remain to be discovered, and that these pathways might be fundamental in the amino acid metabolism of the microbial community from Laguna Negra, Argentina.

Short title: Genome of *E. pavilionensis* str. N139

Keywords

Exiguobacterium, High Altitude Andean Lakes, UV resistance, Arsenic resistance, bacterial metabolism, tryptophan biosynthesis, Extremophiles, Metals or Metalloids

Abbreviations

HAALs: high altitude Andean Lakes ANI: Average Nucleotide Identity LM: Lake Medium
SCCCore: Single Copy Core SSGs: Strain Specific Genes HGT: Horizontal Gene Transfer
BCAA: Branched Chain Amino Acids PER: Photoenzymatic Repair
NER: Nucleotide Excision Repair PRR: Post Replication Repair

Introduction

The high altitude Andean Lakes (HAALs) from Puna, Argentina, are a group of lakes located at 3000-6000 meters above sea level which are characterized by high ultraviolet (UV) radiation and salinity, broad temperature variations, low nutrient concentrations and high contents of metals and metalloids, mainly arsenic (Fernández-Zenoff et al., 2006; Fernández-Zenoff, Siñeriz & Farías, 2006; Dib et al., 2008; Flores et al., 2009; Ordoñez et al., 2009; Albarracín et al., 2011; Belfiore, Ordoñez & Farías, 2013). These environmental conditions are considered to be extreme and might resemble those of the Earth's early atmosphere, as has been stated by NASA (Cabrol et al., 2007; Farías et al., 2009). Hence, these geographical areas have been proposed for studies on astrobiology (Farías et al., 2009). Despite being oligotrophic and hostile, a great microbial diversity has been found in the HAALs, where bacteria from the genus *Exiguobacterium* are one of the dominant taxa (Ordoñez et al., 2009, 2013; Sacheti et al., 2013).

The *Exiguobacterium* genus, a sister clade to the *Bacillus* genus, is currently underexplored, and molecular studies of this genus from different sources are limited (Vishnivetskaya, Kathariou & Tiedje, 2009). Exploring *Exiguobacterium* strains is of great significance because understanding their strategies to adapt to diverse and extreme environmental conditions will likely place them as model organisms involved in the remediation of organic and inorganic pollutants. In particular, *Exiguobacterium* strains isolated from the HAALs have the potential of becoming an attractive model system to study environmental stress responses, as these microorganisms are able to grow efficiently in the laboratory (Ordoñez et al., 2009; Belfiore, Ordoñez & Farías, 2013). Moreover, Dib *et al.* suggested that these microorganisms could harbor various stress defense associated systems (Dib et al., 2008).

The *Exiguobacterium pavilionensis* str. N139 was selected for genome sequencing due to its stress defense mechanisms such as its tolerance to high UV-B radiation, salinity and metalloids, particularly arsenic. This strain was isolated from the water column of Laguna Negra, which belongs to the ‘Salar de la Laguna Verde’, a system of five shallow oligotrophic lakes originated in the Tertiary (65 million to 1.8 million years ago).

In the present study we characterized the genome of *E. pavilionensis* str. N139, in order to identify the strategies that this organism employs to cope with the extreme environmental factors present in the aforementioned lake, mainly those related to metal and UV-B resistance.

Classification and features

Members of the *Exiguobacterium* genus are Firmicutes, Gram-positive, facultative anaerobes with a low G + C content (Vishnivetskaya, Kathariou & Tiedje, 2009). *Exiguobacterium* is widely distributed all over the world (Karami et al., 2011) and has been isolated and typified from a wide variety of environments including hot springs (Vishnivetskaya, Kathariou & Tiedje, 2009; Vishnivetskaya et al., 2011), hydrothermal vents (Crapart et al., 2007), permafrost (Vishnivetskaya & Kathariou, 2005; Vishnivetskaya et al., 2006; Rodrigues et al., 2008), marine sediment (Kim et al., 2005), oligotrophic environments (Rebollar et al., 2012), biofilms (Carneiro et al., 2012), alkaline methanogenic microcosms (Rout, Rai & Humphreys, 2015) and more recently in water and microbial mats from high-altitude desert wetlands (Ordoñez et al., 2013). The *Exiguobacterium* genus is divided in two main phylogenetic clades (Vishnivetskaya, Kathariou & Tiedje, 2009); clade I is composed of temperate and cold-adapted strains, whereas clade II includes alkaliphilic species, with a marine origin and/or from high-temperature habitats (Figure 1A).

E. pavilionensis str. N139, which belongs to clade II, was isolated from the water column of Laguna Negra, in the HAALs (GPS: 27°38'49" S, 68°32'43" W) and in laboratory conditions can uptake a wide variety of carbon sources (Table S1). Its cells are short rods and do not sporulate (Figure 2, Table 1).

Materials and Methods

Genome project history

Our group is currently sequencing several *Exiguobacterium* strains isolated from different oligotrophic ecosystems including different lakes in the Cuatrociénegas basin, México and in the HAALs, Argentina, in order to understand how these bacteria adapt to poor nutrient availability. In addition, the *E. pavilionensis* str. N139 was selected for its observed ability to cope with high UV-B radiation and metal resistance (data not shown).

Growth conditions and genomic DNA preparation

E. pavilionensis str. N139 was isolated from Laguna Negra by plating it in Lake Medium (LM). LM was used to maintain the same salinity as the isolation environment and was obtained by filtering lake water (0.22 µm Biopore filters) and adding 2.5 g of yeast extract and 12 g of agar (Difco) per liter at 20 °C. For future assays the strain was grown in LM broth at 20 °C with agitation. DNA was extracted using the protocol described by (Fernández-Zenoff, Siñeriz & Fariás, 2006).

Microscopy

Differential interference contrast (DIC) images were obtained from cells grown on LB medium overnight, and mounted in No. 2 coverslips (Figure 2). LB medium was used as

mounting media during image acquisition. Images were shot with an Olympus FV1000 Laser Scanning Confocal on an Olympus IX81 inverted microscope equipped with 60x UPlanSApo NA 1.3 Sil objective lens. With a 405nm laser line, DIC Images were acquired in the TD channel controlled with Olympus FV10-ASW-4.2 software. Brightness, contrast and scale bars were adjusted on displayed images using the Fiji software.

Phylogenetic Reconstruction

For the phylogenetic analysis 16S rRNA gene sequences for all *Exiguobacterium* strains whose genome sequences have been completed were used (*Exiguobacterium acetylicum*, *E. antarcticum*, *E. marinum*, *E. oxidotolerans*, *E. sibiricum* 255-15, *Exiguobacterium* sp. 8-11-1, *Exiguobacterium* sp. AT1b, *Exiguobacterium* sp. GIC31, *E. pavilionensis* str. RW-2, *Exiguobacterium* sp. S17 and *E. undae*). Furthermore, the 16S sequences from other *Exiguobacterium* strains relevant for this analysis (*E. arabatum*, *E. mexicanum*), and from other Firmicutes that were used as outgroups (*Bacillus anthracis* str. AMES, *Oceanobacillus iheyensis*, *Bacillus subtilis* str. 168 and *Bacillus hablodurans* str. C125) were also included. All 16S rRNA sequences were downloaded from the SILVA database, with the exception of the 16S rRNA sequence from *Exiguobacterium* sp. MH3 which was downloaded from NCBI. All sequences were manually checked for length and quality; only high quality sequences, longer than 1,400 bp were included in the analysis. Sequences were aligned with *ssu-align* and then masked with *ssu-mask* (Nawrocki, Kolbe & Eddy, 2009). Positions of the bases that are part of stems or loops according to their secondary structure were calculated with *esl-alistat* from the *Infernal* package to obtain a better alignment (Nawrocki & Eddy, 2013). The dataset was partitioned into stems and loops and treated under different evolutionary models. *Ad hoc* scripts were written to integrate all the position's information in a final nexus file alignment. The resulting file was used

as the input for the Bayesian phylogenetic reconstruction with *MrBayes* v 3.2.5 (Ronquist & Huelsenbeck, 2003). Substitutions in stem regions were modeled considering the co-variation of the paired nucleotides, with the doublet model (Schöniger & Von Haeseler, 1994). For the loop regions of the 16S rRNA, a traditional 4×4 model was used. With the data partitioned in this fashion, and the whole gene being subjected to a GTR model with invariable gamma, two sets of 3,000,000 iterations were run, sampling and saving every 100th tree to a file, with the first 250 trees discarded. A majority-rule consensus was used to examine estimates of posterior probabilities, interpreted as nodal support. Figure 1A shows the phylogenetic reconstruction of all *Exiguobacterium* species from both clades. These analyses placed the strain N139 as most similar to *E. pavilionensis* str. RW-2 (White III, Grassa & Suttle, 2013), which is coherent with the average nucleotide identity (ANI) analyses (see below). ANI calculations were done for N139 *versus* all other complete genomic sequences of *Exiguobacterium*, and these two strains, along with *Exiguobacterium* sp. GIC31, belong to the same species (Table S2).

Genome sequencing and assembly

The genome of *E. pavilionensis* str. N139 was generated using *454 technology* (Table 2). A standard *454 Titanium* library was constructed and sequenced, producing 664,086 reads, totaling 253.9 Mb of data. The 454 data was assembled with *Newbler*, version 2.8 and MIRA, version 3.4 (Chevreux et al., 2004). Both assemblies were merged using *Minimus2*, from the *amos* version 3.1.0, with assembly errors manually corrected. The contigs were sorted with *Mauve* version 2.3.1 (Rissman et al., 2009), using *Exiguobacterium* sp. AT1b as the reference because it is the closest relative with a completely sequenced genome (Vishnivetskaya et al., 2011). The final assembly consists of 23 contigs, the smallest one being 457 bases in length and the largest 1.5 Mb, with an average coverage of 85×

Genome annotation

Protein-coding genes, tRNAs, rRNAs and non-coding RNAs were identified using the annotation pipeline *Prokka* (Seemann, 2014), followed by annotation refinement with *InterProScan* (Quevillon et al., 2005). Riboswitches were identified with the *Infernal* 1.1 package (Nawrocki & Eddy, 2013) using the corresponding covariance models from the *Rfam* database (Burge et al., 2013). COGs were assigned by profile hidden Markov model (profile HMM) searches using the *hmmsearch* program of the *HMMER3* package (Mistry et al., 2013). For every COG, a multiple sequence alignment of *bona fide* representative sequences were generated using the *Muscle* program (Edgar, 2004), and then, the corresponding Hidden Markov Model was built using the *hmmesbuild* program, also provided in the *HMMER3* package (Mistry et al., 2013). The resulting annotation was subjected to manual curation. *Pathway Tools 13* (Karp et al., 2009) in combination with the *BioCyc* (Caspi et al., 2014) and *UNIPROT* (Consortium, 2015) databases were used to infer the metabolic capacities of *E. pavilionensis* str. N139. The curated model of *E. pavilionensis* str. N139 can be provided upon request, and will be deposited in the *BioCyc* database.

Results and Discussion

Genome Properties

The genome of *E. pavilionensis* str. N139 includes three circular megaplasms with probable sizes of 250.57, 137.48 and 48 Kb, as determined by Pulse Field Gel Electrophoresis (PFGE) analysis (see Figure S1 and Supplemental Material) and one circular chromosome with an estimated size of 2,516 kb, with a 52% GC content. A total of 3,182 genes were predicted (3,049 protein-coding genes and 82 noncoding RNA genes (95.8% and 2.57% respectively)). *E.*

184 *pavilionensis* str. N139 has 10 ribosomal rRNA operons, confirmed by PFGE (see Supplemental
185 Material and Figure S2). A putative function was assigned to 2,214 (73%) of the protein-coding
186 genes, and the remaining genes were annotated as hypothetical proteins. The properties and the
187 statistics of the genome are summarized in Table 3. 2,575 protein-coding genes were assigned to
188 1,603 COG families, corresponding to a gene content redundancy of 38.1% (see Table 4).

189 **Genome Rearrangements**

190 To explore the genomic rearrangements present on *E. pavilionensis* str. N139 in
191 comparison to other *Exiguobacterium* species, nucleotide syntenic blocks were obtained with
192 *Mauve* version 2.3.1 (Darling et al., 2004). Syntenic block permutations were exported and used
193 as input for *MGR* (Bourque & Pevzner, 2002). *MGR* was used to calculate the minimum number
194 of rearrangements between the species analyzed, and to recover the rearrangement dendrogram.
195 *genoPlotR* (Guy, Kultima & Andersson, 2010) was used to plot the syntenic blocks (Figure 1B).
196 Genome rearrangements within clades I and II are scarce, showing high conservation of the
197 genomic structure within clades. However, several genomic rearrangements occurred as both
198 clades diverged.

199 In order to determine which contigs of *E. pavilionensis* str. N139 belong to plasmids, the
200 plasmid sequences of pEspA and pEspB from *E. arabatum* RFL1109 (Jakubauskas et al., 2009)
201 were retrieved from NCBI. This strain was selected for comparison because their plasmids have
202 been widely studied (Jakubauskas et al., 2009) and because it is phylogenetically close to *E.*
203 *pavilionensis* str. N139. Jakubauskas and colleagues identified the regions hr-A1, hr-AB and hr-
204 A2 in plasmid pEspA as capable of replicating the plasmid in *Bacillus*. For plasmid pEspB, they
205 hypothesized that the regions hr-B1, hr-AB and hr-B2 are involved in a theta replication

mechanism (Jakubauskas et al., 2009). BLAST searches of these regions were performed against all *Exiguobacterium* genome sequences available to date. For the strains *E. MH3*, *E. antarcticum* and *E. AT1b*, which are described as genomes without plasmids, no significant hits were found. Conversely, hits to the *E. arabatum* sequences hr-B1, hr-AB-B and hr-B2 (a fragment of 39 kb) were found in the genomes of *E. GIC3* (56 kb) and *E. N139* (contig000014 of size 25 kb). It was concluded that the sequences present in the plasmids are shared within different *Exiguobacterium* strains, displaying a highly dynamic behavior, and as a result, determining which of our contigs correspond to the three megaplasmsids observed in the PFGE experiments was not possible (see Supplemental Material). Furthermore, contig 14 in our assembly corresponds to the smallest contig of *E. GIC3*, so it could be a plasmid in both *Exiguobacterium* strains. However, contig 14 lies adjacent to contig 13, both accounting for a total size of 100 kb when synteny was evaluated against *E. pavillionensis* RW-2. It is worth mentioning that contig 13 possesses most of the genes responsible for metals resistance, but this region appears to be integrated in the chromosome of *E. GIC3*. This highly dynamic behavior across strains suggests that, if both contigs belong to a plasmid, it might be an integrative one. A MAUVE analysis performed between the strains N139, GIC3 and *E. pavillionensis* RW-2 shows high synteny across their chromosomes. This idea that contigs 12, 13 and 14 might belong to the plasmids is supported by their shifts in GC skew (Figure 3). To all appearances, the chromosomes within each of the two main clades of the *Exiguobacterium* species are very similar, but quite distinct when compared between these clades (Figure 1).

The *Exiguobacterium* strain N139 belongs to the *pavillionensis* species

ANI calculations of all clade II *Exiguobacterium* strains were performed and compared to our N139 strain, suggesting that *E. pavillionensis* str. RW-2, *Exiguobacterium* sp. GIC31 and this

N139 strain belong to the same species since they share ANI values above 97% (Table S2) (Goris et al., 2007). Typically, the ANI values between genomes of the same species are above 95% (e.g., *E. coli*). Also relying on the ANI calculations, it was concluded that the outgroup of the *E. pavilionensis* species could be *E. mexicanum*. To better assess if *E. mexicanum* belongs to the same species, additional experimental support is required, since its genome is 400 genes bigger than the remaining members of the *E. pavilionensis* clade.

Exiguobacterium clade II pangenomes

To further understand the genomic properties of the three *E. pavilionensis* strains, their pangenome was built along with their putative outgroup, *E. mexicanum*. This pangenome comprises all their 4,100 genes; 2,524 of them belonging to a Single Copy Core (SCCore) Genome (Figure S3). Orthologs were first calculated following the OrthoMCL pipeline (Li, Jr & Roos, 2003; Fischer et al., 2011), and the pangenome and the SCCore were elucidated using *ad hoc* perl scripts. The same process was repeated for all *Exiguobacterium* strains from clade II whose complete genomes were available at the time of analysis. The pangenome of the nine *Exiguobacterium* from clade II is composed of 5,267 genes; 2,116 belonging to the SCCore and 1,664 being Strain Specific Genes (SSGs). The resulting pangenome shows a very conserved and cohesive pool of genes, despite their evolutionary distance and their remote geographic locations. Over two thousand genes compose the SCCore Genome, which represents a large core genome when compared to other pangenomes (Lefebure & Stanhope, 2007; Rasko et al., 2008; Rouli et al., 2015; Zhang & Qiu, 2015), and taking into account that the average genome size of *Exiguobacterium* strains is approximately three thousand genes. SSGs could have been acquired by Horizontal Gene Transfer (HGT) and retained to adapt to these diverse environments, or equally likely, lost in some of the living taxa, due to lack of selective pressure in their respective

niches. The SSGs are represented in a heatmap on Figure S4 where the clusterization of the *Exiguobacterium* strains is based on the presence (and abundance) or absence of their COG assignation. *Exiguobacterium* sp. S17 and *E. mexicanum* are exceptional for the fact that they possess a large pool of SSGs (Table S3).

Fifty-nine of the SSGs found in the *E. pavilionensis* str. N139 were mapped on its genome to see if their distribution followed some bias (Figure 3). Throughout the contigs that are putative chromosomal regions, the SSGs appear to be randomly distributed. However, some of the SSGs are concentrated in the contigs 12 and 13, supporting the previous idea that these contigs may be part of the megaplasmiids seen in the PFGE analysis (Figure S1). COGs were assigned to the SSGs as previously described for the *E. pavilionensis* str. N139 genome. For the whole set of SSGs of the pangenome, COGs were successfully assigned to 66% of the genes, and are represented in a heatmap (Figure S4). However, most of the N139 SSGs could not be assigned to COGs, and for those that were successfully classified, the vast majority falls in the S and R (Poorly Characterized) COG categories, leaving open questions on which may be the unique strategies that N139 employs to adapt to the particular environment of Laguna Negra.

Main Metabolic Pathways, Amino acids, Nucleotides and Cofactors

Based on its genomic content, *E. pavilionensis* str. N139 is probably a chemoheterotroph since it has two copies of *aioB* arsenite oxidase, which means it could obtain energy from arsenite oxidation. It has the complete pathway for glycolysis and it could synthesize acetyl-CoA, succinyl-CoA and isobutanoyl-CoA. It is a heterolactic fermenter, being able to produce lactate from pyruvate and ethanol from acetaldehyde. It has a complete TCA cycle, and it lacks the first two steps of the pentose phosphate pathway, but the rest of the pathway is present. Hence, its central metabolism is similar to *B. subtilis* [48–50], but *E. pavilionensis* str. N139 can

275 synthesize more fermentation products, namely ethanol and formate. *E. pavilionensis* str. N139
 276 lacks the routes for synthesizing *de novo* phenylalanine and tyrosine, as well as the Branched
 277 Chain Amino Acids (BCAA). However, it can synthesize tyrosine from phenylalanine, since it
 278 has the phenylalanine-4-hydroxylase regulated by a Tyr (UAC codon) T box riboswitch. Despite
 279 lacking the complete pathways for BCAA biosynthesis, it preserves the *ilvE* gene, a BCAA
 280 aminotransferase, which could probably synthesize any of the three BCAAs from available
 281 precursors. An interesting note on its tryptophan biosynthesis is that its biosynthetic operon is
 282 split in two transcription units: *trpEG* and *trpDCFBA*, which are separated in the chromosome,
 283 but co-regulated by a Trp T box riboswitch. Although this regulation is common in Firmicutes
 284 (Gutierrez-Preciado et al., 2005; Gutiérrez-Preciado, Yanofsky & Merino, 2007), the genome
 285 context of the *trp* operon is not, and it is interesting that this separation takes place at the
 286 synthesis of anthranilate. Moreover, the *trpEG* genes are regulated by a single T box, whilst the
 287 *trpDCFBA* operon is regulated by two T boxes in tandem. This could either mean that the
 288 separation of the pathway is a recent event and the regulation is being settled in order to
 289 coordinate both transcriptional units; or that this strain requires anthranilate (the product of
 290 *trpEG*) for something else. Certainly, one possibility is that *E. pavilionensis* str. N139 exports
 291 anthranilate for a syntrophy with a partner(s) and the subsequent steps of the tryptophan
 292 biosynthetic pathway require a stricter regulation in order for the genes *trpDCFBA* to be
 293 expressed. Since *E. pavilionensis* str. N139 lacks the biosynthetic pathways for five amino acids,
 294 a likely scenario is that this bacterium is sharing metabolites with other partners in Laguna
 295 Negra. This is supported by the observation that it is able to form part of a biofilm (data not
 296 shown), and that in all of the amino acids tested it can only grow on serine and asparagine as a
 297 sole carbon source (see Table S1). Based on the metabolite tracer from Pathway Tools, it can be

inferred that *E. pavilionensis* str. N139 could synthesize phenylalanine as well as valine from serine or asparagine. In the same fashion, it cannot grow with phenylalanine as the sole carbon source. Therefore, the configuration of the genes involved in amino acid metabolism might represent a requirement of amino acid syntrophy that needs further exploration and testing. A second possibility is that *E. pavilionensis* str. N139 is utilizing anthranilate for some novel pathway. Anthranilate cannot be in excess with respect to tryptophan, since its excess could decrease the availability of phosphoribosyl pyrophosphate (PRPP) for histidine synthesis (and other reactions) (Merino, Jensen & Yanofsky, 2008). This novel pathway could be involved in different functions that require either tryptophan or anthranilate as intermediates. Examples of these functions are quorum sensing molecules in *Pseudomonas aeruginosa* (Farrow & Pesci, 2007), to plant hormones in *Azospirillum brasilense* (Ge, Xie & Chen, 2006), violacein in *Chromobacterium violacein* (Antônio & Creczynski-Pasa, 2004) or antibiotics as in *Streptomyces coelicolor* (Amir-Heidari, Thirlway & Micklefield, 2008).

The regulation of biosynthetic and transporter genes through riboswitches is common in Firmicutes, specially the members of Bacilli class. It has also been observed that transport and biosynthesis of the same metabolite tend to be part of a regulon mediated by *in cis* elements, like riboswitches (Gutiérrez-Preciado et al., 2009). Methionine can be synthesized and imported through several strategies. Several SAM riboswitch regulated operons coding for Met transporters were identified in the genome of *E. pavilionensis* str. N139, as well as canonical *met* biosynthetic genes. An interesting case is the methionine salvage pathway, whose genes are encoded in two divergent operons, both regulated by divergent SAM riboswitches. Both operons must be transcribed in order for the Yang cycle to be completed. In one operon, genes *mtnK* and *mtnA* are transcribed along with three ribose transporters, *rbsB*, *rbsC* and *araG*. Lysine

biosynthesis (from aspartate via diaminopimelate) and transport are part of a regulon under the lysine riboswitch. Furthermore, through the identification of riboswitches, two transporters from the NhaC family were annotated: one as a methionine transporter (SAM riboswitch), and the other one as a lysine transporter (LYS riboswitch). This strategy of improving gene annotation through the knowledge of the gene's regulation has been previously explored (Rollins, 2002; Gutiérrez-Preciado & Merino, 2012; Gutiérrez-Preciado et al., 2015).

Cofactors. Thiamine can be synthesized *de novo*, its biosynthesis and its uptake are regulated by the TPP riboswitch. Moreover, the analysis of *E. pavilionensis* str. N139 genome indicates that a new thiamine transporter could be present in this bacterium. The gene *exiN139_02072* is automatically identified as a membrane protein, but it seems to be regulated by a TPP riboswitch. Experimental evidence is needed for the confirmation and characterization of this transporter, which could unveil a new family of thiamine transporters. Riboflavin biosynthesis and transport (RibU) are also co-regulated through a FMN riboswitch.

Nucleotides. In the genome of *E. pavilionensis* str. N139 the purine *de novo* biosynthetic pathway is encoded in a huge transcription unit regulated by a purine riboswitch. Other transcription units in the same regulon include a monocystronic GMP synthase, and genes involved in adenine and adenosine salvage pathway.

Genomic Adaptations to an Extreme Environment

Laguna Negra is an aquatic ecosystem that harbors extreme environmental conditions such as high levels of UV-B (10.65 wm^2), high salinity levels (32%), scarce nutrients, particularly phosphorous (<005 mg/l), high metal contents including the metalloid arsenic

(3mg/l), an alkaline pH and large daily temperature fluctuations (ranging from 20 °C during the day to −40 °C at night) (Flores et al., 2009); (see Table 1).

Resistance to metals and metalloids

In Laguna Negra, ubiquitous Arsenic enters the *E. pavilionensis* str. N139 cells through existing transporters due to its high structural similarity with other molecules (Rosen, 1999) and induces oxidative stress responses (Oremland & Stolz, 2003). Furthermore, arsenite (AsO_2H) and arsenate (AsO_4^{3-}), are both toxic molecules. Arsenite binds to reduced cysteines in proteins inactivating them, and arsenate is a molecular analog of phosphate and therefore inhibits oxidative phosphorylation (Oremland & Stolz, 2003). Arsenate is far less toxic than arsenite, hence the oxidation of arsenite is considered a detoxification process. However, the oxidation of arsenite to arsenate, when coupled to the reduction of oxygen to water, is an exergonic process, and it has been suggested that at least some bacteria may derive energy out of this process (vanden Hoven & Santini, 2004). *E. pavilionensis* str. N139 has an arsenite oxidase, *aiob*, enabling it to oxidize arsenite. This is an important metabolic capability, because it uses arsenite as an electron donor. Moreover, from a bioremediation point of view, this former metabolic feature is important since arsenite is more soluble than arsenate, so it can facilitate the removal of As in solution. *E. pavilionensis* str. N139 also has an arsenite efflux pump, *arsB*, as well as an ATPase that provides energy to ArsB for extrusion of arsenite and antimonite, *arsA*, co-transcribed with *arsD*, an arsenic chaperone for the ArsAB pump (Páez-Espino et al., 2009). Hence, this bacterium can probably detoxify and extrude As, as well as oxidize arsenite acquiring energy from this process. *E. pavilionensis* str. N139 also possesses redundancy for mercury detoxification, harboring four paralogous copies of *merA*. Briefly, MerA is the key detoxification enzyme of the mercury resistance system, reducing Hg^{2+} to Hg^0 (Silver & Phung,

2005). Hg is toxic due to its high affinity to sulfur (Nies, 2003) and usually, *mer* resistance genes are co-transcribed in an operon whose dissemination is common by horizontal gene transfer (HGT) (Barkay, Miller & Summers, 2003). In this organism, two copies of *merA* are present in a monocistronic fashion; a third one is transcribed with a hypothetical protein. A fourth copy is co-transcribed with *merR*, the regulatory protein of the system. Two *mer* transporters which uptake Hg and *merP*, a transporter with a Sec-type signal, which could import Hg as a neutral chloride or hydroxide and deliver it to the other Mer transporters, which will finally transfer it to MerA.

The most common mechanism of resistance to metals consists of efflux pumps for inorganic ions. However, As and Hg resistance mechanisms are unique in the sense that these elements are reduced to lower their toxicity [66], instead of being exported. *E. pavilionensis* str. N139 is resistant to cadmium, zinc, cobalt, and copper by pumping it out from the cell. It has two membrane embedded Cd^{2+} efflux pumps, one of which can also extrude zinc and cobalt; two paralogous copies of *copA* and *copB*, two P-type ATPase systems for exporting copper, and *cueR*, a sensing cytoplasmic Cu that protects periplasmic proteins from copper-induced toxicity. *copB* is transcribed monocistronically, and each of the *copA* genes form an operon co-transcribed with a copy of *copZ*, a copper chaperone, but one is co-transcribed with a glutaredoxin, whilst the other is co-transcribed with *csrR*, a copper-sensitive operon repressor.

Resistance to UV radiation

Another extreme environmental condition in Laguna Negra is high ultraviolet radiation, particularly UV-B (Flores et al., 2009; Ordoñez et al., 2009). Bacteria have different UV damage repair pathways, including photoenzymatic repair (PER), nucleotide excision repair (NER) also called dark repair, and recombinational repair (PRR) or post-replication repair (Goosen &

388 Moolenaar, 2008). *E. pavilionensis* str. N139 has three genes (exiN139_00335 (*phrB*),
 389 exiN139_01768 and exiN139_00235) related to photolyases, which are involved in PER. They
 390 use UV as energy source (using FADH and transferring electrons) and catalyze the
 391 monomerization of cyclobutyl pyrimidine dimers. The gene exiN139_00335 only has
 392 homologues in Firmicutes including other known *Exiguobacterium*, and exiN139_01768 has
 393 homologues in Firmicutes, Cyanobacteria, α - and γ - Proteobacteria, and Euryarcheotes.
 394 Additionally, exiN139_00235 is a cryptochrome, which are flavoproteins related to photolyases.
 395 Cryptochromes do not repair DNA and are presumed to act in other (unknown) processes, such
 396 as entraining circadian rhythms (Yuan et al., 2012).

397 *E. pavilionensis* str. N139 has also genes for NER. Its genome encodes the UvrABC
 398 endonuclease, a complex that recognizes DNA damage, binds to the damaged segment and
 399 cleaves it. Additionally, it codes for PcrA (also known as UvrD), a helicase in charge of
 400 removing the excised segment recognized and cleaved by UvrABC. These genes are regulated by
 401 the SOS response, which uses LexA as a repressor inactivated by RecA (Minko et al., 2001).

402 Regarding the PRR, *E. pavilionensis* str. N139 encodes for RecA, which recognizes SSB
 403 and cleaves UmuD, which becomes UmuD' and binds UmuC to generate polymerase V, which in
 404 turn repairs damages, sometimes causing mutations. The gene exiN139_03003 may produce
 405 polymerase IV that is also involved in DNA damage repair (Sommer, Bailone & Universitaire,
 406 1998). UmuC is found in the genome, however UmuD is missing. It is possible that a protein
 407 highly similar to an existing copy of LexA may be taking its role, given that both can be cleaved
 408 by RecA and are present in *Exiguobacterium*.

Finally, it is likely that *E. pavilionensis* str. N139 participates in biofilm formation in Laguna Negra along with other bacteria (unpublished results). Analyses of other *Exiguobacterium* have shown that they participate in marine biofilms interacting with other Firmicutes and Proteobacteria (López et al., 2006; Carneiro et al., 2012). Evidence of possible biofilms associated genes originates from two *loci* present in the genome of *E. pavilionensis* str. N139. The first *locus* encoding a protein capable of producing alginate, a linear co-polymer of two uronic acids that is produced in its acetylated form by some bacteria for adherence of these bacteria to target cell walls by the creation of a biofilm (Ramphall & Pier, 1985). The second *locus* codes for the arginine deiminase system, which can function at very low pH and is thought to be a critical factor in oral biofilm pH homeostasis (Burne & Marquis, 2000).

Conclusions

E. pavilionensis str. N139 lives in a high-altitude, salted lake exposed to intense UV radiation, about 300 km away from the nearest ocean, the Pacific. Many factors in *E. pavilionensis* str. N139 metabolism, such as the fact that it needs to uptake certain intermediates like phenylalanine and BCAAs, and the possible excretion of the overproduced anthranilate, suggest that it is a key player in the amino acid metabolism of a microbial consortium that inhabit Laguna Negra. Moreover, the excess of anthranilate that it may produce could be directed to some novel pathway that remains to be uncovered, such as a new antibiotic, a new pigment or a new quorum sensing molecule.

Additionally, this microorganism lives in a low phosphorous environment, and relies on strategies for phosphorous uptake, like the presence of high-affinity Pi transporters and its regulation (*pstS*, *pstCAB*, *phoB*, *phoR*, *dedA* and *ptrA*) and genes for polyphosphate storage and breakdown (*ppk* and *ppx*). Organisms that scavenge phosphate can sometimes uptake the

structurally similar arsenate ion, and hence also depend on arsenate detoxification mechanisms. This *Exiguobacterium* is not only able to detoxify this metalloid but also metals like mercury, cadmium, zinc, cobalt, and copper; and it has a complete defense system against UV damage. It is also able to thrive in the alkaline environment of Laguna Negra since its genome code for all the typical antiporters present in alkaliphilic bacilli (*nhaC*, *nhaP*, the *mpr* operon, *yhaU*, *norM* and *mleN*). These antiporters present also contribute to a moderate salinity resistance (Ventosa, Nieto & Oren, 1998; Padan et al., 2005), and this could also be related with the maintenance of metal resistance strategies in its genome, since it has been shown that lowering the salinity can lead to enhanced sensitivity to cadmium, cobalt and copper (Ventosa, Nieto & Oren, 1998). With all these characteristics, *E. pavilionensis* str. N139 is an excellent candidate for future biotechnological research.

Although our study generates more questions than the ones it could solve, by sequencing its genome we have gained insights on the strategies the strain N139 employs for thriving in its habitat. From its Strain Specific set of genes, only 23 out of 59 could be annotated and classified to a COG, and still, most of the COG-classified genes belong to the poorly characterized category. This set of genes of unknown function require further experimental work to completely unveil how the strain N139 is adapting to the extreme environment of Laguna Negra.

Figure 1

Evolutionary history of the genus *Exiguobacterium*

A) Phylogenetic reconstruction with the 16S rRNA gene using MrBayes (see Methods). The values of those branches that are not supported by 100% MrBayes parametric bootstrap, are shown in black. The phylogeny is rooted with a *Bacillus* outgroup. The genus *Exiguobacterium* separates in two clades: I, dominated by psychrophilic and II, dominated by alkaphilic species with a marine origin. **B) Synteny among *Exiguobacterium* strains.** Nucleotide syntenic blocks are represented by colored bars. Red links denote no rearrangements between the blocks compared. Blue links denote rearrangements between the blocks compared. Blue numbers in the phylogeny denote the minimum number of rearrangements obtained with *MGR*. Plasmids from *E. sibiricum* are displayed at the right (separated from the chromosome by backslashes). SILVA Accession Numbers of the sequences used are as follows: *B. anthracis* str. Ames AE017334; *B. subtilis* str. 168, AL009126; *B. halodurans* str. C-125, BA000004; *O. iheyensis*, BA000028; *E. marinum*, AY594266; *E. sp.* AT1b, CP001615; *E. arabatum*, FM203124; *E. sp.* S17, FN994191; *E. sp.* 8-11-1, KC757126; *E. aurantiacum*, DQ019166; *E. sp.* GIC31, EU282458; *E. mexicanum*, JX094173; *E. pavilionensis* str. RW-2, ATCL01000001; *E. acetylicum*, DQ019167; *E. undae*, FN870071; *E. oxidotolerans*, AB105164; *E. antarcticum* str. B7, CP003063; *E. sibiricum* str. 255-15, CP001022. The sequence from *E. sp.* MH3 was retrieved from its genome (NCBI accession number: NC_022794).

Figure 2

Differential interference contrast image of *E. pavilionensis* str. N139

**Note: Auto Gamma Correction was used for the image. This only affects the reviewing manuscript. See original source image if needed for review.*

Figure 3(on next page)

Circular genome map of *E. pavilionensis* str. N139

Circle tracks from out towards inside are as follows: 1) Length in nucleotides for each contig; 2) Coding Sequences (CDS) in the Forward Strand (light blue); 3) CDS in the reverse strand (dark blue); 4) Strain Specific Genes (SSGs) in the forward strand (light purple); 5) SSGs in the reverse strand (dark purple); 6) GC Skew (gray). Skew and gene distribution follow that of a typical Firmicute genome. The Strain Specific Genes in the contigs that belong to the chromosome appear to be randomly distributed, whilst they seem to be concentrated in the contigs 12 and 13, which are probably the ones belonging to megaplasmaids. The circular plot was done with Circos software (Krzywinski et al., 2009).

Table 1(on next page)

Classification and general features of *Exiguobacterium pavilionensis* str. N139

^a Evidence codes - IDA: Inferred from Direct Assay; TAS: Traceable Author Statement (i.e., a direct report exists in the literature); NAS: Non-traceable Author Statement (i.e., not directly observed for the living, isolated sample, but based on a generally accepted property for the species, or anecdotal evidence); EXP: Inferred from Experiment. These evidence codes are from the Gene Ontology project (“Gene Ontology Evidence Codes”)

Table 1. Classification and general features of *Exiguobacterium pavilionensis* str. N139

Property	Term	Evidence code ^a
Classification	Domain <i>Bacteria</i>	TAS (Woese, Kandler & Wheelis, 1990)
	Phylum Firmicutes	TAS (Gibbons & Murray, 1978)
	Class Bacilli	TAS (De Vos et al., 2009)
	Order Bacillales	TAS (De Vos et al., 2009)
	Family Bacillales <i>Family XII. Incertae Sedis</i>	TAS (De Vos et al., 2009)
	Genus <i>Exiguobacterium</i>	TAS (De Vos et al., 2009; Vishnivetskaya, Kathariou & Tiedje, 2009)
	Species <i>Exiguobacterium pavilionensis</i>	TAS (White III, Grassa & Suttle, 2013)
	Strain: <i>N139</i> (Accession: <i>JMEH000000000</i>)	
Gram stain	<i>Positive</i>	IDA
Cell shape	<i>Short rods</i>	IDA
Motility	<i>Motile</i>	IDA
Sporulation	<i>Non-sporulating</i>	EXP
Temperature range	<i>Mesophilic (30 - 37°C)</i>	IDA
Optimum temperature	<i>30°C</i>	IDA
pH range; Optimum	<i>7-9</i>	IDA
Carbon source	<i>β-Methylglucoside, Galacturonic acid, L-asparagine, Tween 40, L-Serine, N-acetylglucosamine, Hydroxybutyric acid, Itaconic acid, Ketobutyric acid, Putrescine (See table S1)</i>	EXP
Habitat	<i>Aquatic</i>	TAS (Flores et al., 2009)
Salinity	<i>0.11% - 10% NaCl (w/v)</i>	IDA
Oxygen requirement	<i>Facultatively anaerobic</i>	TAS (De Vos et al., 2009)
Biotic relationship	<i>free-living</i>	IDA
Pathogenicity	<i>non-pathogen</i>	NAS
Geographic location	<i>Laguna Negra, Catamarca, Argentina</i>	IDA
Sample collection	<i>2006</i>	IDA
Latitude	<i>27°39'20.17"S</i>	IDA
Longitude	<i>68°33'46.18"W</i>	IDA
Altitude	<i>4100 masl</i>	IDA

^a Evidence codes - IDA: Inferred from Direct Assay; TAS: Traceable Author Statement (i.e., a direct report exists in the literature); NAS: Non-traceable Author Statement (i.e., not directly observed for the living, isolated sample, but based on a generally accepted property for the species, or anecdotal evidence); EXP: Inferred from Experiment. These evidence codes are from the Gene Ontology project ("Gene Ontology Evidence Codes")

Project information

1 **Table 2.** Project information.

Property	Term
Finishing quality	Permanent-draft
Libraries used	454 pyrosequence standard library
Sequencing platforms	454 Titanium
Fold coverage	85 x
Assemblers	Newbler 2.8 and MIRA 3.4
Gene calling method	Prokka
Locus Tag	EF88
Genbank ID	JMEH000000000.1
GenBank Date of Release	December, 2015
GOLD ID	Go0093977
BIOPROJECT	PRJNA245187
Source Material Identifier	N139
Project Relevance	UV resistance, metal resistance, adaptation to oligotrophic environments

2

Table 3(on next page)

Nucleotide content and gene count levels of the *E. pavilionensis* str. N139 genome

a) The total is based on either the size of the genome in base pairs or the total number of protein coding genes in the annotated genome.

Table 3. Nucleotide content and gene count levels of the *E. pavilionensis* str. N139 genome

Attribute	Genome (total)	
	Value	% of total ^a
Genome size (bp)	2,952,588	-
DNA coding (bp)	2,655,834	89.94
DNA G+C (bp)		52
DNA Scaffolds	23	
Total genes	3,182	100
RNA genes	82	2.62
Protein-coding genes	3,049	95.82
Pseudogenes	26	0.81
Genes in internal clusters	NA	
Genes with function prediction	2,356	74.04
Genes assigned to COGs	2,575	80.92
Genes with Pfam domains	2,538	79.76
Genes with signal peptides	NA	
Genes with transmembran helices	888	27.90
CRISPR repeats	0	

a) The total is based on either the size of the genome in base pairs or the total number of protein coding genes in the annotated genome.

Table 4(on next page)

Genes associated with the 25 general COG functional categories

a) The total is based on the total number of protein coding genes in the annotated genome.

1 **Table 4.** Genes associated with the 25 general COG functional categories

Code	Value	% of total ^a	Description
J	166	5.44	Translation, ribosomal structure and biogenesis
A	0	0	RNA processing and modification
K	235	7.71	Transcription
L	144	4.72	Replication, recombination and repair
B	1	0.03	Chromatin structure and dynamics
			Cell cycle control, Cell division, chromosome partitioning
D	36	1.18	
V	62	2.03	Defense mechanisms
T	166	5.44	Signal transduction mechanisms
M	144	4.72	Cell wall/membrane biogenesis
N	75	2.46	Cell motility
U	53	1.74	Intracellular trafficking and secretion
			Posttranslational modification, protein turnover, chaperones
O	100	3.28	
C	152	4.99	Energy production and conversion
G	232	7.61	Carbohydrate transport and metabolism
E	224	7.35	Amino acid transport and metabolism
F	84	2.76	Nucleotide transport and metabolism
H	97	3.18	Coenzyme transport and metabolism
I	81	2.66	Lipid transport and metabolism
P	170	5.58	Inorganic ion transport and metabolism
			Secondary metabolites biosynthesis, transport and catabolism
Q	54	1.77	
R	463	15.19	General function prediction only
S	327	10.72	Function unknown
-	447	15.55	Not in COG

2 ^aThe total is based on the total number of protein coding genes in the annotated genome.
