Piwi (P-element induced wimpy testis) is an important gene involved in stem cell maintenance and gametogenesis in vertebrates. However, in most invertebrates, especially mollusks, the function of *Piwi* during gametogenesis remains largely unclear. To further understand the function of *Piwi* during gametogenesis, full-length cDNA of *Piwi1* from scallop *Chlamys farreri* (*Cf-Piwi1*) was characterized, which consisted of a 2,637 bp open reading frame encoding an 878-amino acid protein. *Cf-Piwi1* mRNA was mainly localized in the spermatogonia, spermatocytes, and oogonia, oocytes of early development and intra-gonadal somatic cells. Additionally, the knockdown of *Cf-Piwi1* by injection of *Cf-Piwi1*-dsRNA (double-stranded RNA) into scallop adductor led to a loss of germ cells in *C. farreri* gonads. Apoptosis was observed mainly in spermatocytes and oocytes of early development, as well as a small number of spermatogonia and oogonia. Our findings indicate that *Cf-Piwi1* is essential for gametogenesis in the scallop *C. farreri*.

17 **Abstract**

18 *Piwi* (P-element induced wimpy testis) is an important gene involved in stem cell
19 maintenance and gametogenesis in vertebrates. However, in most invertebrates, especially
20 mollusks, the function of *Piwi* during gametogenesis remains largely unclear. To further
21 understand the function of *Piwi* during gametogenesis, full-length cDNA of *Piwi1* from scallop
22 *Chlamys farreri* (*Cf-Piwi1*) was characterized, which consisted of a 2,637 bp open reading frame
23 encoding an 878-amino acid protein. *Cf-Piwi1* mRNA was mainly localized in the
24 spermatogonia, spermatocytes, and oogonia, oocytes of early development and intra-gonadal
25 somatic cells. Additionally, the knockdown of *Cf-Piwi1* by injection of *Cf-Piwi1*-dsRNA
26 (double-stranded RNA) into scallop adductor led to a loss of germ cells in *C. farreri* gonads.
27 Apoptosis was observed mainly in spermatocytes and oocytes of early development, as well as a
28 small number of spermatogonia and oogonia. Our findings indicate that *Cf-Piwi1* is essential for
29 gametogenesis in the scallop *C. farreri*.

30 Introduction

31 Gametogenesis is the basis of animal reproduction and mainly includes germ stem cell self-
32 renewal, meiosis and maturation of gametes. Studies of gametogenesis will help improve the
33 reproductive ability and preservation of economically important species. It is known that many
34 genes are involved in this process for model organisms, but the roles of these genes remain
35 largely unknown in non-model organisms.

36 Piwi (P-element induced wimpy testis), a PIWI subfamily member of the Argonaute
37 superfamily, is identified based on two conserved domains, PAZ and PIWI (Cerutti et al. 2000).
38 The PAZ domain, at the center of the amino acid sequence, contains a typical single stranded
39 nucleic acid binding motif that can bind to the 3' end of short RNA (Lingel et al. 2003; Yan et al.
40 2003). The PIWI domain, found in the C-terminal region, functions to maintain Piwi's stability
41 and is structurally similar to the RNase H catalytic domain (Liu et al. 2004; Song et al. 2004).

42 The *Piwi* gene was first identified in *Drosophila melanogaster* and demonstrated a
43 potentially important role in maintaining germ cells (GCs) (Lin and Spradling 1997).
44 Subsequently, *Piwi* homologues were reported in a variety of species, including *Caenorhabditis*
45 *elegans*, *Bombyx mori*, *Danio rerio*, *Coturnix coturnix* and *Homo sapiens* (Lau et al. 2001;
46 Sasaki et al. 2003; Houwing et al. 2008; Chen et al. 2012; Tatsuke et al. 2014). The expression of
47 the *Piwi* gene is mostly restricted to gametogenesis and early embryonic development, but its
48 expression pattern and functions are not consistent in different animals (Deng and Lin 2002;
49 Megosh et al. 2006; Carmell et al. 2007; Houwing et al. 2008; Wang and Reinke 2008). In *D.*
50 *melanogaster*, *Piwi* mutants eliminate the self-renewing division of germ stem cells (GSCs), and
51 overexpressing *Piwi* in the germlarium somatic cells results in an increase in number of GSCs
52 and the rate of mitosis (Cox et al. 1998). In the flatworm *Macrostomum lignano*, knockdown of
53 *Piwi* results in a complete elimination of all stem cells, including GSCs and somatic stem cells
54 (De Mulder et al. 2009). Tatsuke et al. (2014) suggested that Siwi (the silkworm homologue of
55 the Piwi protein) recruits HP1 proteins to a target site guided by the Piwi-piRNA complex, and
56 then the Piwi-HP1 complex functions as a rapid transcriptional repressor to regulate gene

57 expression in *B. mori*.

58 Mollusks are one of the most abundant and biologically diverse groups in the animal
59 kingdom. Identifying early GCs is beneficial to the study of gametogenesis. However, it is
60 difficult in histological sections of the mollusk gonads to distinguish various types of germ cells
61 accurately, especially for the early development stages, because some features, such as cell size
62 and karyoplasmic ratio, are diverse in different sections. These problems limit the study on the
63 molecular mechanism of gametogenesis in mollusk. In this study, we cloned full-length cDNA of
64 *Piwil* in the scallop *Chlamys farreri*, a commercially important bivalve mollusk in China, and
65 revealed its expression characteristics in the gonads during gametogenesis. Furthermore, the role
66 of *C. farreri Piwil* (*Cf-Piwil*) in the scallop during gametogenesis was examined using RNAi.
67 Our aims are to demonstrate the function of *Cf-Piwil* during gametogenesis and investigate its
68 potential feasibility as a molecular marker to identify early GCs in the scallop gonads.

69 **Materials and methods**

70 **Ethics Statement**

71 The collection and handling of the scallops *C. farreri* were performed in accordance with the
72 Institutional Animal Care and Use Committee of the Ocean University of China and the local
73 government.

74 **Specimen collection and sampling**

75 Adult *C. farreri* scallops with a mean shell height of 6.28 ± 0.43 cm were collected from
76 Shazikou (Qingdao, China). Gonads were dissected into 0.2 cm^3 pieces. Some of these pieces
77 were fixed in 4% paraformaldehyde in 0.1 M phosphate buffer (pH 7.4) at 4°C for 24 h,
78 dehydrated through serial methanol dilutions (25, 50, 75 and 100%) and stored in pure methanol
79 at -20°C for *in situ* hybridization (ISH). Some other pieces were fixed in Bouin's solution (picric
80 acid, saturated aqueous solution - 75 ml; formalin, 40% aqueous solution - 25 ml; acetic acid,
81 glacial - 5 ml) for 24 h and then stored in 70% ethanol for histological observation. The

82 remaining pieces were immediately frozen in liquid nitrogen and stored at -80°C for total RNA
83 isolation. All the reagents used without specific indication were provided by Sangon Biotech
84 (Shanghai, China).

85 **Histology**

86 Gonads stored in 70% ethanol were dehydrated in an ethanol dilution series, cleared with
87 xylene, and embedded in paraffin wax according to the description of Liu et al. (2014). Sections
88 were made at 5 µm thickness and stained with hematoxylin and eosin. Observations and digital
89 images were taken with a Nikon E80i microscope (Nikon, Tokyo, Japan).

90 Gonads were divided into four stages according to previously described morphological
91 characteristics (Liu et al. 2012). The gonadosomatic indices (GSI = gonad weight/soft tissue
92 body weight × 100%) are defined as resting stage (GSI 3.73% for females and 3.49% for males),
93 proliferative stage (GSI 4.32% for females and 4.38% for males), growing stage (GSI 5.39% for
94 females and 5.42% for males) and mature stage (GSI 14.29% for females and 12.48% for males).

95 **Total RNA extraction and reverse transcription**

96 Total RNA was extracted using the thiocyanate–phenol–chloroform method according to
97 Chomczynski et al (1987). Quality and quantity of the RNA were measured using agarose gel
98 electrophoresis and spectrophotometry. Reverse transcription for full-length cDNA cloning and
99 qRT-PCR were performed according to manufacturer instructions using the SMARTer™ RACE
100 cDNA Amplification Kit (Clontech, Mountain View, USA) and Primescript™ RT reagent Kit
101 with gDNA Eraser (Perfect Real Time) (Takara, Otsu, Japan), respectively.

102 **Cloning and sequence analysis of full-length cDNA**

103 A *Piwil* cDNA fragment of 311 bp was obtained from the *C. farreri* transcriptome (Wang et
104 al., 2013) and compared to the National Center for Biotechnology Information (NCBI) database
105 using BLASTX. Amplification of 5'- and 3'-RACE were conducted with scallop testis cDNA
106 and two specific PCR primers (PR-5': 5'-GCAACAGACATCAACATCTGTTTCTTGG-3', PR-

107 3': 5'-ATGCTGATTGGAGCAGAGATCTTCGTGG-3') according to the SMART™ RACE
108 cDNA Amplification Kit protocol (Clontech, Mountain View, USA). PCR products were gel-
109 purified and cloned into the pMD18-T vector (Takara, Otsu, Japan) then transformed into
110 *Escherichia coli* DH5α competent cells (Takara, Otsu, Japan). Positive clones were selected and
111 sequenced. The full-length cDNA sequence was assembled using DNASTAR, Lasergene version
112 7.1.

113 The identity and similarity of the deduced amino acid sequence were analyzed with other
114 known PIW11 (*Homo sapiens*, *Mus musculus*, *Sus scrofa*, *Gallus gallus*, *Caprimulgus*
115 *carolinensis*, *Xenopus tropicalis*, *Danio rerio*, *Alitta virens*, *Lottia gigantea*, *Crossostrea gigas*,
116 *Mytilus galloprovincialis*, *Caenorhabditis elegans*) in GenBank using the online BLASTX tool.
117 Multiple alignments were performed using the software CLUSTALX version 1.81 and
118 DNAMAN version 8.0. We conducted a phylogenetic analysis using the neighbor-joining
119 method in MEGA 5.0 with 1,000 bootstrap replicates (Koichiro et al. 2011).

120 **qRT-PCR analysis**

121 qRT-PCR was conducted using SYBR Green Real-Time PCR Master Mix (TOYOBO,
122 Osaka, Japan) and an ABI 7500 Real-Time PCR System (Applied Biosystems, Foster City,
123 USA). A parallel amplification of the *C. farreri elongation factor 1α* (*EF-1α*) reference transcript
124 (GenBank accession no. AEX08674.1) was performed to normalize expression data of *Cf-Piwi1*
125 transcripts. Two pairs of specific primers, *Piwi1F*-1: 5'-CGGAGGCGTTGTGTGTAGCA-3',
126 *Piwi1R*-1: 5'-CTGTCCATCCCCAACACCATC-3' for amplifying a 193 bp of *Cf-Piwi1*, and
127 *EF-1αF*: 5'-ATCCTTCCTCCATCTCGTCCT-3', *EF-1αR*: 5'-
128 GGCACAGTTCCAATACCTCCA-3' for amplifying an 86 bp of *Cf-EF-1α* were designed. RT-
129 PCR conditions consisted of an initial denaturation step at 95°C for 30 s followed by 40 cycles of
130 5 s of denaturation at 95°C and 30 s of annealing and extension at 60°C. Gonads from five
131 individuals at each developmental stage were sampled, and triplicate assays for each gonad
132 cDNA were conducted. The data were analyzed using the ABI 7500 system SDS software
133 version 1.4 with automatically set baseline and cycle threshold values. Relative *Cf-Piwi1* mRNA

134 levels were calculated based on the $2^{-\Delta\Delta C_t}$ method.

135 All data are presented as the means \pm standard error of five samples with three parallel
136 repetitions. Differences between the means were tested using one-way analysis of variance
137 (ANOVA) followed by least significant difference tests with the significance level set at $P < 0.05$
138 in SPSS version 17.0.

139 **Tissue ISH**

140 DIG-labeled RNA sense and anti-sense probes were synthesized from a 557 bp fragment of
141 *Cf-Piwi1* from sites 3078 to 3634 according to instructions with the DIG RNA Labeling kit
142 (Roche, Basel, Switzerland). Gonads stored for tissue ISH were cleared in xylene and embedded
143 in paraffin wax before sectioning at 5 μm for testes and 7 μm for ovaries. Sections were fixed to
144 a slide with 0.1% polylysine for 10 h at 37°C. Before washing three times with PBST
145 (phosphate-buffered saline with 0.1% Tween 20) and digesting with proteinase K (2 $\mu\text{g ml}^{-1}$) for
146 15 min at 37°C, samples were dewaxed in xylene and rehydrated through a descending series of
147 methanol dilutions. After fixing with 4% paraformaldehyde for 1 h and prehybridizing at 60°C
148 for 6 h in hybridization buffer (50% formamide, 5% SSC, 5 mM EDTA, 100 mg ml^{-1} ribonucleic
149 acid, 1.5% blocking reagent, 0.1% Tween 20), samples were hybridized with digoxigenin (DIG)-
150 labeled probes at 1 mg ml^{-1} in hybridization buffer for 16 h at 60°C. Following hybridization,
151 samples were washed in maleic acid buffer (0.1 M maleic acid, 0.15 M NaCl, 0.1% Tween 20,
152 pH 7.5) and incubated with alkaline phosphatase-conjugated anti-DIG antibody from DIG
153 Nucleic Acid Detection Kit (Roche, Basel, Switzerland) at 4°C. After staining with NBT/BCIP
154 (Roche, Basel, Switzerland) for 3 h at room temperature, the sections were counterstained with
155 1% neutral red. Hybridization signals were detected and photographed using a Nikon E80i
156 microscope (Nikon, Tokyo, Japan).

157 **dsRNA synthesis**

158 A 726 bp fragment of *Cf-Piwi1* cDNA from sites 11 to 736 was amplified using the primers
159 *Piwi1F-2*: 5'-TAATACGACTCACTATAGGGTTGAGAGGCAAGAAGTAACA-3' and

160 *PiwiIR-2*: 5'-TAATACGACTCACTATAGGGGTACAGATGAAGGCACTGTG-3' (T7
161 promoter sequence underlined) with *C. farreri* testis RNA as the template. The purified PCR
162 fragment was transcribed, and the double-strand RNA (dsRNA) was synthesized *in vitro* using
163 T7 MEGAscript RNAi Kits (Ambion, Austin, USA) according to manufacturer instructions.
164 Quality and quantity of the *PiwiI*-dsRNA was measured by 1% agarose gel electrophoresis and
165 spectrophotometry.

166 **dsRNA injection and sampling**

167 Scallops with a mean shell height of 6.13 ± 0.54 cm at the proliferative stage were collected
168 from Shazikou (Qingdao, China) and maintained in aerated running filtered seawater and fed
169 with single cell algae during the experiment. A total of 75 scallops were randomly assigned to 3
170 groups. Scallops from the dsRNA group and PBS group were injected with 25 μg *Cf-PiwiI*
171 dsRNA diluted in 100 μl PBS and 100 μl PBS only into adductor muscle, respectively. Scallops
172 in the blank group were not injected with anything. Two injections were conducted during the
173 experiment, at the beginning and at day 7 of the experiment. On the 3rd day after injection, 3
174 scallops from each group were removed randomly, and their gonads were sampled as described
175 above to estimate the *Cf-PiwiI* knockdown effect. On the 10th day, 8 scallops (5 males and 3
176 females) from each group were sampled again.

177 **Types of germ cells quantification**

178 Five- μm gonadal sections were conducted from scallops of each group following the
179 method mentioned in Histology. To determine the effect of *Cf-PiwiI* knockdown, five squares
180 ($6400 \mu\text{m}^2$ for ovary and $1600 \mu\text{m}^2$ for testis) of the sections were randomly picked to calculate
181 the mean number and composition of germ cells in the gonads of each group. Differences
182 between cell quantities of different groups were tested using one-way analysis of variance
183 (ANOVA) followed by least significant difference tests with the significance level set at $P < 0.05$

184 in SPSS version 17.0.

185 **TUNEL assay**

186 Five- μm sections of the gonads were prepared after the RNAi experiment. To detect *in situ*
187 cell apoptosis, a TUNEL (terminal deoxynucleotidyl transferase-mediated dUTP nick end
188 labeling) assay was performed using a TdT-mediated dUTP apoptosis detection kit (Promega,
189 Madison, USA) with a hematoxylin counterstain. The sections were observed and photographed
190 using a Nikon E80i microscope (Nikon, Tokyo, Japan).

191 **Results**

192 **Sequence and characteristics of the *Cf-Piwi1* full-length cDNA**

193 The full length of the *Cf-Piwi1* cDNA was 4,986 bp (GenBank accession number:
194 KR869093) with a 59 bp 5' untranslated region (UTR), a 2,290 bp 3' UTR and a 2,637 bp open
195 reading frame (ORF), encoding a putative protein of 879 amino acids, with a predicted molecular
196 weight of 99.34 kDa and theoretical isoelectric point of 9.16. Multiple alignment indicated that
197 the predicted protein contained a PAZ domain and a PIWI domain (Fig. S1) and was highly
198 homologous to other known PIWI1, with 57% identity to *Crassostrea gigas*, 51% to *Danio rerio*
199 and 53% to *Homo sapiens*. Phylogenetic analysis showed that the predicted *Cf-Piwi1* first
200 clustered with *C. gigas* and *M. galloprovincialis*, and then followed established evolutionary
201 hypotheses (Fig. 1).

202 **Quantitative expression of *Cf-Piwi1* mRNA in *C. farreri* gonads during the reproductive** 203 **cycle**

204 Expression levels of *Cf-Piwi1* in *C. farreri* gonads increased significantly from the resting to
205 the mature stage (Fig. 2 I and II). *Cf-Piwi1* expression in testes at the mature stage was
206 approximately 2.5 times higher than that of the resting stage. In ovaries, it was about two-fold
207 higher at the mature stage than the resting stage. No significant differences in *Cf-Piwi1*

208 expression levels were observed between the ovary and testis at the same developmental stages
209 ($P > 0.05$).

210 **Cytolocation of *Cf-Piwi1* mRNA in *C. farreri* gonads during gametogenesis**

211 *Cf-Piwi1* mRNA was mainly located in GCs during early development. In ovaries, *Cf-Piwi1*
212 transcripts were detected in oogonia, oocytes of early development and intra-gonadal somatic
213 cells (ISCs) of germinal acini, but no positive signal was detected in mature oocytes (Fig. 2 III a-
214 d). In testes, obvious positive signals were observed in spermatogonia, spermatocytes and ISCs
215 of germinal acini. However, no positive signal was visible in spermatids and spermatozoa (Fig.
216 2 III e-i). Moreover, no positive signal was detected in gonads using sense probes (Fig. 2 III b0,
217 d0, g0).

218 ***Cf-Piwi1* knockdown led to abnormal development and apoptosis of GCs**

219 qRT-PCR detected that levels of the *Cf-Piwi1* mRNA decreased significantly in the gonads
220 of the dsRNA group than that of the PBS and Blank groups. The reduction of *Cf-Piwi1*
221 expression levels in the *C. farreri* gonads between the first injection and the second injection in
222 the dsRNA group was very similar, and the declines in the ovaries and testes were approximately
223 30% or 35% of that in the blank group, respectively (Fig. 3 I and II).

224 To investigate the effects of *Cf-Piwi1* deficiency on gametogenesis, we performed a
225 histological analysis. *Cf-Piwi1*-dsRNA provoked several defects in development of GCs in both
226 testes and ovaries. Compared with scallops from control groups, most oocytes in the ovaries of
227 dsRNA scallops were at early developmental stage and many of them were stained darkly and
228 presented abnormal morphological characteristics, implying that *Cf-Piwi1* downregulation might
229 inhibit oocyte development (Fig. 3 III a-f). In the testes of the *Cf-Piwi1* knockdown scallops, the
230 arrangement of GCs in the germinal acini became loose, spermatids occurred only in few
231 germinal acini and the number of spermatids was smaller compared visually to that of the blank
232 and PBS groups (Fig. 3 III g-l). Furthermore, we quantified the number and composition of germ

233 cells in each group. In ovaries, more than half number of all kinds of germ cells decreased after
234 knocking down of *Cf-Piwi1*, but the proportion of *Cf-Piwi1* expression cells (ISC 36.3%,
235 oogonia 30.5% and oocyte 33.2%) increased when comparing with control groups (ISC 32.1%,
236 oogonia 35.7% and oocyte 18.2%) (Fig. 4 I , Table S1). Similar results were obtained in testis
237 with the percentage of spermatogonia and spermatocyte changed from 11.4% and 67.2% of the
238 control groups to that of 38.2% and 54.5% after RNAi (Fig. 4 II , Table S2). Interestingly, we
239 also found in some germinal acini of the *Cf-Piwi1* knockdown scallops, number of spermatocytes
240 greatly decreased while spermatogonia and spermatids persisted (Fig. 3 III i&l).

241 The TUNEL assay results revealed that some of the oogonia and many oocytes were in the
242 process of apoptosis in the ovaries of the dsRNA scallops, and the majority of spermatocytes and
243 partial spermatogonia in *Cf-Piwi1* knockdown testes were undergoing apoptosis (Fig. 4 III c, f, i,
244 l). Few apoptotic cells were found in the gonads of the blank and PBS groups (Fig. 4 III a, b, d, e,
245 g, h, j, k).

246 Discussion

247 *Cf-Piwi1* expression pattern in GCs is similar to that of fish

248 Localizations of *Piwi* transcripts are diverse in gonads of different species, although they are known
249 to express mainly in GCs. In the planarian *Schmidtea mediterranea*, *Piwi* mRNA is visible in somatic
250 stem cells and GCs (Reddien et al. 2005; Rossi et al. 2006; Palakodeti et al. 2008). In *D. melanogaster*,
251 *Piwi* is expressed in all the cells of gonads (Cox et al. 2000). In *D. renio*, *Ziwi*, a *Piwi* homologue, is
252 found only in GCs of gonads, where its expression appears to be the strongest in GCs at the mitotic and
253 early meiotic stages (Houwing et al. 2008). Similarly, in medaka (*Oryzias latipes*), *Piwi* is expressed in
254 spermatogonia, spermatocytes and all ovarian GCs (Li et al. 2012). In *M. musculus*, *Miwi* expression
255 appears to be restricted to the primary spermatocytes, secondary spermatocytes and the elongating
256 spermatids, and no expression is observed in somatic cells of testis (Deng and Lin 2002). In this study,

257 *Cf-Piwi1* mRNA was expressed in male and female GCs of early development, which differs from that in
258 mammals but is similar to that in fish.

259 ***Cf-Piwi1* is possibly a molecular marker for early GCs**

260 Yano et al. (2008) reported that *rtili*, a homolog of *Piwi* in the rainbow trout *Oncorhynchus mykiss*, is
261 expressed specifically in spermatogonia, and is used as a molecular marker to identify spermatogonia. In
262 this study, we found that *Cf-Piwi1* expression was not only restricted to spermatogonia, but was also
263 specifically visible in the GCs of early development, such as spermatogonia, spermatocytes, oogonia, and
264 oocytes of early development. Thus, it can be potentially used to identify the GCs of early development in
265 the testes and ovaries of *C. farreri*.

266 ***Cf-Piwi1* is essential for gametogenesis in *C. farreri***

267 In model animals, the roles of *Piwi* on gametogenesis are diverse, but *Piwi* defects always result in
268 the loss of GCs, reductions in nurse cell, poorly-developed egg chambers, and complete female sterility
269 (Lin and Spradling 1997). Cox et al. (1998) reported that *Piwi* mutations in *D. melanogaster* cause loss of
270 GCs, but no dead cells were detected, which implies that the loss of *Piwi* can eliminate the self-renewing
271 division of GSCs. Similarly, in *C. elegans*, decreasing *Piwi* expression by RNAi reduces the proliferation
272 of GSC-equivalent cells (Cox et al. 1998). Moreover, in *Zili* (*Ziwi-like*) mutant zebrafish, almost all GCs
273 are lost yet no apoptosis is present, suggesting that loss is possibly due to their inability to proliferate and
274 differentiate (Houwing et al. 2008). Mutation of a hypomorphic *Zili* allele blocks oogenesis in Meiosis I
275 and induces terminal female sterility (Houwing et al. 2008). However, Houwing et al. (2007) found that
276 the reduction of *Ziwi* in *D. rerio* leads to various spermatogenic cell losses by apoptosis. In *M. musculus*,
277 significant numbers of apoptotic cells were detected in spermatocyte layers due to the loss of *Mili*
278 (Kuramochi-Miyagawa et al. 2004). *Miwi*-knockout mice display a drastic increase in apoptotic cell
279 numbers of testes and spermatogenic arrest at the round spermatid stage (Deng and Lin 2002).
280 Additionally, *Miwi2* mutants exhibit spermatogenic cell apoptosis and predominantly arrest at the
281 leptotene stage of meiosis (Carmell et al. 2007).

282 In this study, we found that knockdown of *Cf-piwi1* lead to significant cell number reduction and

283 most of the remaining germ cells detained at the early development stages, implying its important role in
284 the germ cell proliferation and differentiation. In the meantime, the proportion *Cf-piwi1* expression cells
285 increased after RNA interference also indicated the gametogenic arrest occurred at early development
286 stages, which was accordant with the reported studies. Cell apoptosis assay presented that marked
287 apoptosis occurred mainly in the spermatocytes of the testes and oocytes of the ovaries in *Cf-Piwi1*
288 knockdown scallops, respectively, indicating germ cells at earlier development stages gradually died after
289 earlier accumulation. In addition, small numbers of spermatogonia and spermatids existed despite a great
290 reduction of spermatocytes also demonstrated that spermatogenesis was blocked in spermatocytes. All
291 these results suggest that *Cf-Piwi1* plays an important role in *C. farreri* gametogenesis.

Figure 1

Phylogenetic analysis of Piwi1 among various species based on the multiple sequence alignment.

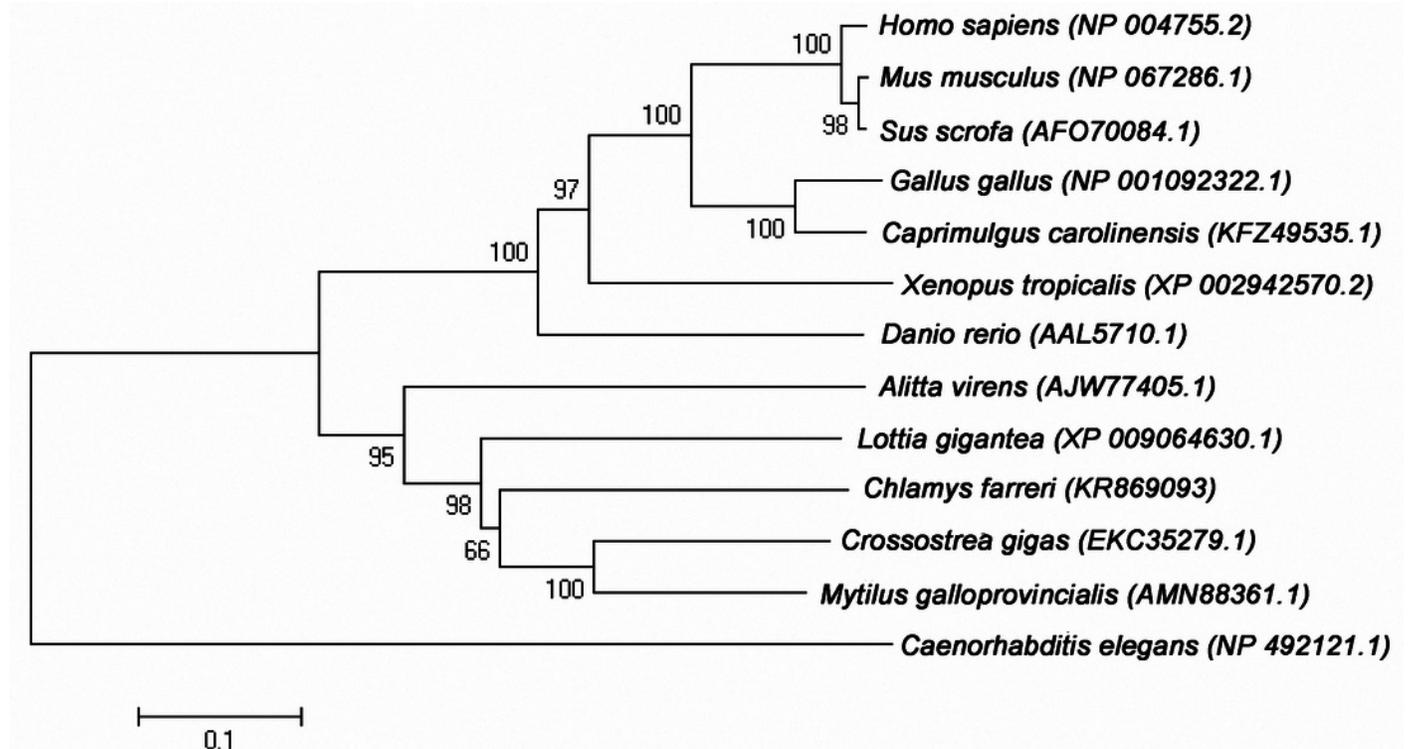

Figure 2

Relative abundance and location of *Cf-Piwi1* mRNA in *C. farreri* gonads.

Relative abundance of *Cf-Piwi1* mRNA detected by qRT-PCR in I) ovary and II) testis. The expression level in gonads at the resting stage was set as 1.00; Values are the mean \pm SEM; n = 3; Different letters indicate statistically significant differences ($P < 0.05$). III). Location of *Cf-Piwi1* mRNA detected by tissue *ISH*. Negative *ISH* using a sense probe (b0, d0, g0). Positive signal from the anti-sense probe is stained in dark blue. (a), (b), (c) and (d), Ovaries at the resting, proliferative, growing, and mature stage, respectively; (e), (f), (g) and (h), Testes at the resting, proliferative, growing, and mature, respectively; (i), a different sight of the same section of (h) under microscope. ISC, Intragonadal somatic cell; Moc, Mature oocyte; Og, Oogonium; Oc, Oocyte; Sg, Spermatogonium; Sc, Spermatocyte; St, Spermatid; Sz, Spermatozoon. Magnification: Bar is 20 μ m.

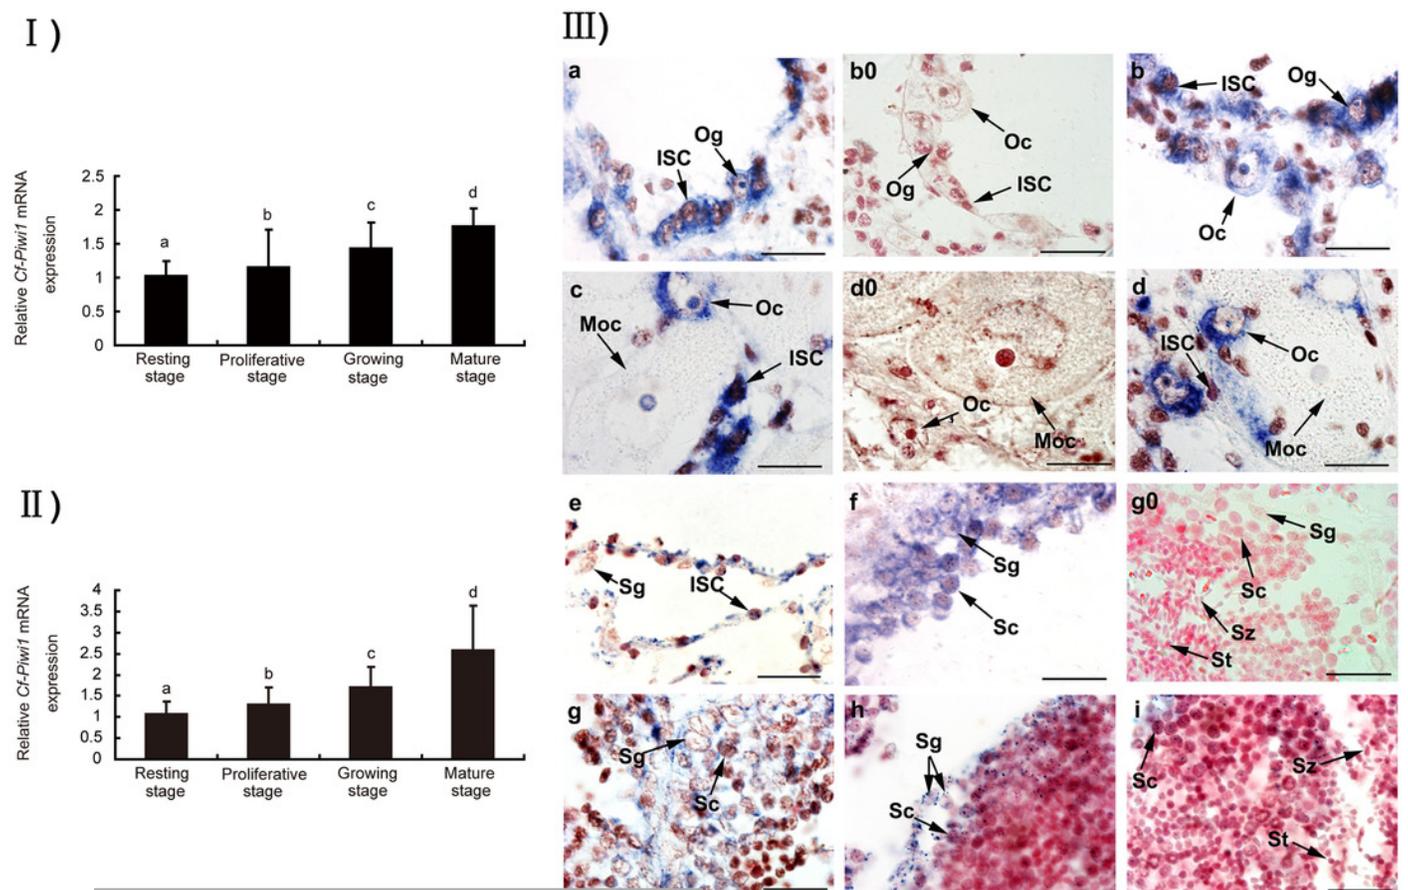

Figure 3

Expression of *Cf-Piwi1* mRNA and histology of scallop gonads after RNAi.

Relative experiment level of *Cf-Piwi1* mRNA detected by qRT-PCR in I) ovary and II) testis on 10th day after RNAi. The expression level in gonads of the blank group was set as 1.00; Values are the mean \pm SEM; $n = 5$ in the testes; $n = 3$ in the ovaries; Different letters indicate statistically significant differences ($P < 0.05$). III). Histological observation of scallop gonads on 10th day after RNAi. (a) and (d), ovary in the blank group; (b) and (e), ovary in the PBS group; (c) and (f), ovary in the dsRNA group; (g) and (j), testis in the blank group; (h) and (k), testis in the PBS group; (i) and (l), testis in the dsRNA group. Dc, Darkly stained cell; Og, Oogonium; Oc, Oocyte; Sc, Spermatocyte; Sg, Spermatogonium; St, Spermatid; Sz, Spermatozoon. Magnification: Bar is $40 \mu\text{m}$ for (a), (b), (c), (g), (h) and (i); Bar is $20 \mu\text{m}$ for (d), (e), (f), (j), (k) and (l).

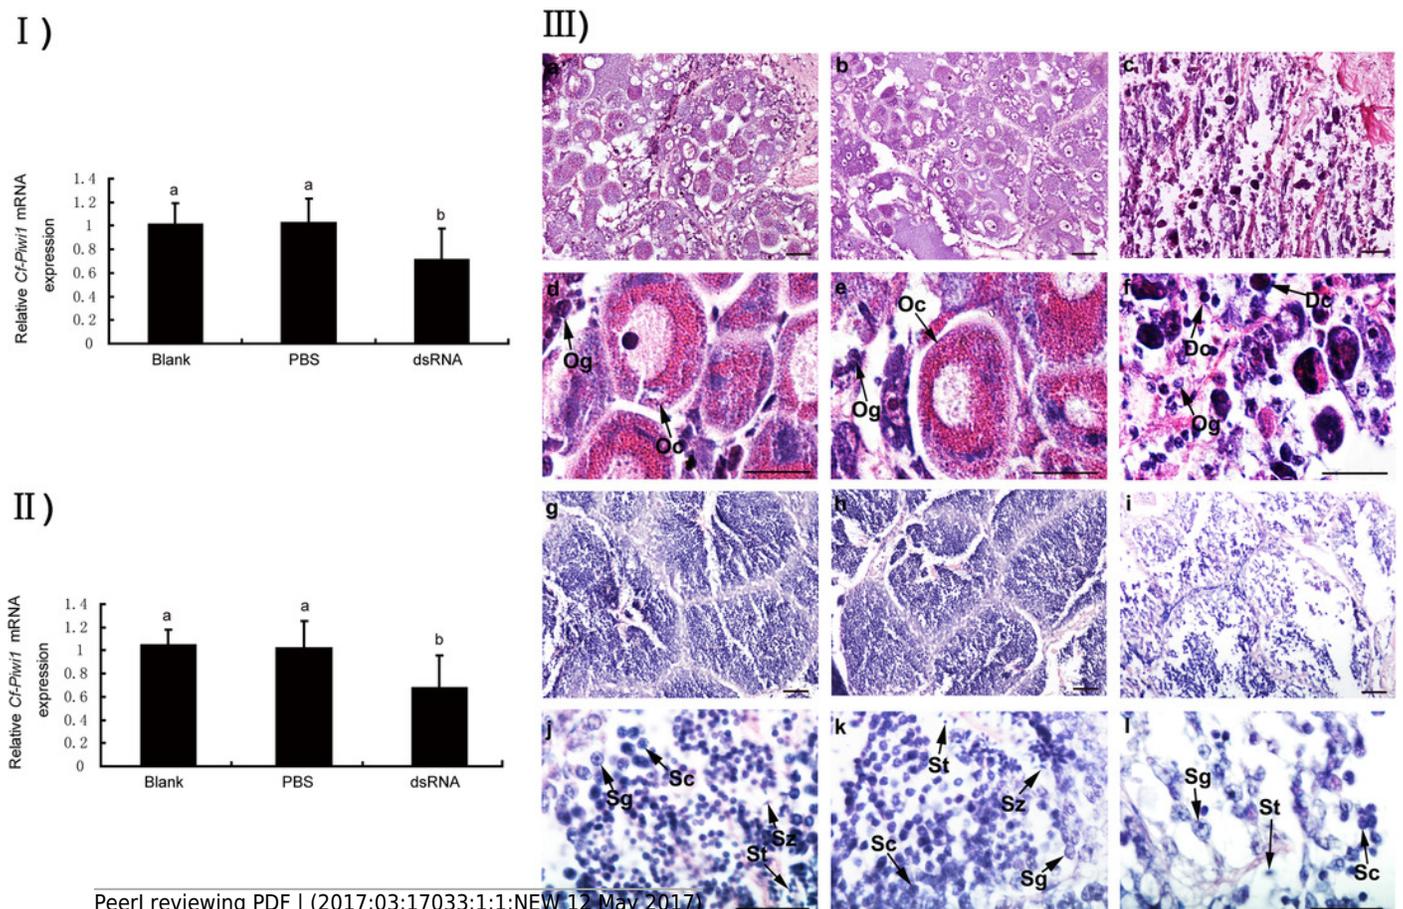

Figure 4

Quantification of the germ cells in scallop gonads after *Cf-Piwi1* knockdown and cell apoptosis analysis.

Quantification of germ cells in I) ovary and II) testis and cell apoptosis detection III) on 10th day after RNAi. (a) and (d), ovary in the blank group; (b) and (e), ovary in the PBS group; (c) and (f), ovary in the dsRNA group; (g) and (j), testis in the blank group; (h) and (k), testis in the PBS group; (i) and (l), testis in the dsRNA group. Apo, apoptosis cell; ISC, Intra-gonadal somatic cell; Moc, Mature oocyte; Og, Oogonium; Oc, Oocyte; Sg, Spermatogonium; Sc, Spermatocyte; St, Spermatid; Sz, Spermatozoon. The values are the mean \pm SEM; $n = 5$ in both testes and ovaries; different letters indicate statistically significant differences ($P < 0.05$). Magnification: Bar is 40 μm for (a), (b), (c), (g), (h) and (i); Bar is 20 μm for (d), (e), (f), (j), (k) and (l).
