Declarations

Involves vertebrate animals.

Please read in full before you begin

How to review

When ready [submit your review online](#). The review form is divided into 5 sections. Please consider these when composing your review:

1. BASIC REPORTING

2. EXPERIMENTAL DESIGN

3. VALIDITY OF THE FINDINGS

4. General comments

5. Confidential notes to the editor

 You can also annotate this PDF and upload it as part of your review

To finish, enter your editorial recommendation (accept, revise or reject) and submit.

BASIC REPORTING

-  Clear, unambiguous, professional English language used throughout.
-  Intro & background to show context. Literature well referenced & relevant.
-  Structure conforms to [PeerJ standards](#), discipline norm, or improved for clarity.
-  Figures are relevant, high quality, well labelled & described.
-  Raw data supplied (see [PeerJ policy](#)).

EXPERIMENTAL DESIGN

-  Original primary research within [Scope of the journal](#).
-  Research question well defined, relevant & meaningful. It is stated how the research fills an identified knowledge gap.
-  Rigorous investigation performed to a high technical & ethical standard.
-  Methods described with sufficient detail & information to replicate.

VALIDITY OF THE FINDINGS

-  Impact and novelty not assessed. Negative/inconclusive results accepted. *Meaningful* replication encouraged where rationale & benefit to literature is clearly stated.
-  Conclusions are well stated, linked to original research question & limited to supporting results.
-  Speculation is welcome, but should be identified as such.
-  Data is robust, statistically sound, & controlled.

The above is the editorial criteria summary. To view in full visit <https://peerj.com/about/editorial-criteria/>

7 Standout reviewing tips

3

The best reviewers use these techniques

Tip

Example

Support criticisms with evidence from the text or from other sources

Smith et al (J of Methodology, 2005, V3, pp 123) have shown that the analysis you use in Lines 241-250 is not the most appropriate for this situation. Please explain why you used this method.

Give specific suggestions on how to improve the manuscript

Your introduction needs more detail. I suggest that you improve the description at lines 57- 86 to provide more justification for your study (specifically, you should expand upon the knowledge gap being filled).

Comment on language and grammar issues

The English language should be improved to ensure that your international audience can clearly understand your text. I suggest that you have a native English speaking colleague review your manuscript. Some examples where the language could be improved include lines 23, 77, 121, 128 - the current phrasing makes comprehension difficult.

Organize by importance of the issues, and number your points

1. Your most important issue
2. The next most important item
3. ...
4. The least important points

Give specific suggestions on how to improve the manuscript

Line 56: Note that experimental data on sprawling animals needs to be updated. Line 66: Please consider exchanging "modern" with "cursorial".

Please provide constructive criticism, and avoid personal opinions

I thank you for providing the raw data, however your supplemental files need more descriptive metadata identifiers to be useful to future readers. Although your results are compelling, the data analysis should be improved in the following ways: AA, BB, CC

Comment on strengths (as well as weaknesses) of the manuscript

I commend the authors for their extensive data set, compiled over many years of detailed fieldwork. In addition, the manuscript is clearly written in professional, unambiguous language. If there is a weakness, it is in the statistical analysis (as I have noted above) which should be improved upon before Acceptance.

Who are the important predators of sea turtle nests at Wreck Rock beach?

Excessive sea turtle nest predation is a problem for conservation management of sea turtle populations. This study assessed predation on nests of the endangered loggerhead sea turtle (*Caretta caretta*) at Wreck Rock beach adjacent to Deepwater National Park in Southeast Queensland, Australia after a control program for feral foxes was instigated. The presence of predators on the nesting dune was evaluated by tracking plots (2 x 1 m) every 100 m along the dune front. There were 21 (2014-2015) and 41 (2015-2016) plots established along the dune, and these were monitored for predator tracks daily over three consecutive months in both nesting seasons. Predator activities at nests were also recorded by the presence of tracks on top of nests until hatchlings emerged. In addition, camera traps were set to record the predator activity around selected nests. The tracks of the fox (*Vulpes vulpes*) and goanna (*Varanus spp*) were found on tracking plots. Tracking plots, nest tracks and camera traps indicated goanna abundance varied strongly between years. Goannas were widely distributed along the beach and had a Passive Activity Index (PAI) (0.31 in 2014-2015 and 0.16 in 2015-2016) eight times higher than that of foxes (PAI 0.04 in 2014-2015 and 0.02 in 2015-2016). Five hundred and twenty goanna nest visitation events were recorded by tracks but no fox tracks were found at turtle nests. Camera trap data indicated that yellow-spotted goannas (*Varanus panoptes*) appeared at loggerhead turtle nests more frequently than lace monitors (*V. varius*) did, and further that lace monitors only predated nests previously opened by yellow-spotted goannas. No foxes were recorded at nests with camera traps. This study suggests that large male yellow-spotted goannas are the major predator of sea turtle nests at the Wreck Rock beach nesting aggregation and that goanna activity varies between years.

24 Abstract

25 Excessive sea turtle nest predation is a problem for conservation management of sea turtle
26 populations. This study assessed predation on nests of the endangered loggerhead sea turtle
27 (*Caretta caretta*) at Wreck Rock beach adjacent to Deepwater National Park in Southeast
28 Queensland, Australia after a control program for feral foxes was instigated. The presence of
29 predators on the nesting dune was evaluated by tracking plots (2 x 1 m) every 100 m along the
30 dune front. There were 21 (2014-2015) and 41 (2015-2016) plots established along the dune,
31 and these were monitored for predator tracks daily over three consecutive months in both
32 nesting seasons. Predator activities at nests were also recorded by the presence of tracks on
33 top of nests until hatchlings emerged. In addition, camera traps were set to record the predator
34 activity around selected nests. The tracks of the fox (*Vulpes vulpes*) and goanna (*Varanus spp*)
35 were found on tracking plots. Tracking plots, nest tracks and camera traps indicated goanna
36 abundance varied strongly between years. Goannas were widely distributed along the beach
37 and had a Passive Activity Index (PAI) (0.31 in 2014-2015 and 0.16 in 2015-2016) eight times
38 higher than that of foxes (PAI 0.04 in 2014-2015 and 0.02 in 2015-2016). Five hundred and
39 twenty goanna nest visitation events were recorded by tracks but no fox tracks were found at
40 turtle nests. Camera trap data indicated that yellow-spotted goannas (*Varanus panoptes*)
41 appeared at loggerhead turtle nests more frequently than lace monitors (*V. varius*) did, and
42 further that lace monitors only predated nests previously opened by yellow-spotted goannas.

43 No foxes were recorded at nests with camera traps. This study suggests that large male yellow-
44 spotted goannas are the major predator of sea turtle nests at the Wreck Rock beach nesting
45 aggregation and that goanna activity varies between years.

46

47

48

49

50 Introduction

51 Sea turtles are oviparous and construct their nests on dunes adjacent to the beach where
52 embryos take about two month to incubate. Sea turtle hatchling nest emergence success is
53 determined by nest temperature, salinity, humidity, water inundation and predation (Fowler
54 1979; Miller 1985; Reid *et al.* 2009). During incubation, a wide range of predators may attack
55 sea turtle nests and have a significant effect on hatchling recruitment and thus long-term
56 population persistence (Stancyk 1995). At many beaches nest predation is the main cause of
57 hatch failure of sea turtles with some regions reporting more than 50% of nests being
58 destroyed by predators (e.g. Fowler 1979; Blamires & Guinea 1998; Blamires *et al.* 2003;
59 Maulany *et al.* 2012; McLachlan *et al.* 2015). A large variety of non-human species have been
60 reported as sea turtle nest predators including, fire ants (*Solenopsis invicta*), crabs (*Ocypode*
61 *cursor*), turkey vultures (*Cathartes aura*), black vultures (*Coragyps atratus*), coatis (*Nasua*
62 *narica*), raccoons (*Procyon lotor*), dogs(*Canis familiaris*), red foxes (*Vulpes vulpes*), golden jackals
63 (*Canis aureus*), mongooses (*Herpestes javanicus*), snakes (*Oligodon formosanus*) and goannas

64 (*Varanus spp*) in different regions of the world (Stancyk *et al.* 1980; Mora & Robinson 1984;
65 Brown & Macdonald 1995; Frick 2003; Leighton *et al.* 2008). In Australia, sea turtle nest
66 predators include several species of native goanna, the native dingo (*Canis lupus*) and the
67 introduced fox (*Vulpes vulpes*), pig (*Sus scrofa*) and wild dog (*Canis familiaris*) (Limpus 1978;
68 Limpus & Fleay 1983). In particular, fox predation of sea turtle nests along the east Australian
69 coast has been problematic and therefore a major focus of sea turtle conservation programs
70 (Limpus 1978; Limpus & Fleay 1983; Limpus 2008).

71

72 The loggerhead turtle (*Caretta caretta*) is an endangered species on the IUCN Red List (IUCN
73 2016). Major breeding aggregations of loggerhead sea turtle include Africa-Mozambique, Oman,
74 the Mediterranean sea, Sri Lanka, Japan, U.S.A. and Australia (Limpus & Limpus 2003). Genetic
75 studies indicate there is little or no interbreeding between these major breeding aggregations
76 (Bowen *et al.* 1993; Limpus 2008). In Australia, two genetically distinct breeding stocks have
77 been identified: an eastern Australian population and western Australian population (Limpus &
78 Limpus 2003). If one breeding stock becomes extinct, it would be difficult to repopulate this
79 area from other genetic stocks. In order to preserve the genetic diversity of loggerheads, it is
80 necessary to protect each of the different populations.

81

82 A significant number of loggerhead turtles nest at Wreck Rock beach adjacent to Deepwater
83 National Park, Queensland, Australia (~400 nests per season, Limpus 2008). Predators of sea
84 turtle nests at Wreck Rock beach include foxes, dingoes and goannas (Limpus 2008). The fox

85 predation of loggerhead turtle nests continued to increase from a modest level when
86 monitoring commenced in 1968–1969 to 90–95% in the mid-1970s (Limpus 2008). From 1987
87 onwards, 1080 poison baits have been used to control fox predation (Limpus 2008), but a
88 recent nest survey (McLachlan *et al.* 2015) indicated that while fox predation of nests was
89 minimal, a large number of nests were predated by goannas. The lace monitor (*Varanus varius*)
90 and yellow-spotted goanna (*Varanus panoptes*) are likely to be the main goannas attacking
91 loggerhead nests because of their distribution along the coastline and ability to dig holes while
92 foraging (Cogger 1993). However, the relative activity levels and impact of these species on
93 loggerhead turtle nests at Wreck Rock beach remain unknown.

94

95 For some animal species, it is difficult to estimate population density by standard census
96 methods such a mark and recapture (Engeman & Allen 2000) because of large home ranges,
97 rough terrain habitats, relatively sparse populations and/or difficulty in capturing animals or
98 making direct observations (Pelton and Marcum 1977). To overcome these problems, Engeman
99 & Allen (2000) developed and refined a passive activity index (PAI) based on the occurrence of
100 tracks on small, pre-defined plots of substrate for monitoring wild carnivore species. This
101 method is simple and quickly applied in the field and can also provide accurate information
102 reflecting population changes over time or space, and simultaneously capture a suite of wildlife
103 species (Engeman & Allen 2000). This method has been used previously to monitor predator
104 activities, including the common water monitor (*Varanus salvator*) activity on an olive ridley
105 turtle (*Lepidochelys olivacea*) nesting beach in Indonesia over two nesting seasons (Maulany

106 2012).

107

108 Despite the anecdotal evidence that foxes and more recently goannas predate a significant
109 number of sea turtle nests at Wreck Rock beach (Limpus 2008; McLachlan et al 2015), no
110 quantitative study of sea turtle nest predation has been conducted at this important nesting
111 beach, and it is not known what species of goanna is responsible for predation. Therefore, the
112 aim of this study was to fill this knowledge gap by quantifying goanna and fox activity on
113 nesting dunes during the sea turtle nesting season at Wreck Rock beach. Three methods were
114 used to achieve this aim. Firstly, tracking plots were used to monitor general activity levels of
115 goannas and foxes along the dunes where sea turtles construct their nests. Secondly, turtle
116 nests were inspected every day until turtle hatchlings emerged in order to record the activities
117 of predators at the nest. Thirdly, camera traps were used to capture predator activity at sea
118 turtle nests so that we could identify which species of goanna was the main predator of these
119 nests.

120

121 Methods

122 Study site and nest marking

123 This study was conducted along the beach for 3 km immediately to the north and south of
124 Wreck Rock adjacent to Deepwater National Park, Southeast Queensland (24°18' 58 S, 151°57'
125 55" E) (Fig. 1). This section of the beach is marked by numbered stakes every 100 m for ease of
126 marking and relocating nests. The beach was monitored nightly by personnel from Turtle Care

127 Volunteers Queensland Inc. to record the presence of emerging female turtles and successful
128 nesting activities. When a nest was located, its position was marked by a red ribbon attached to
129 a small stake and recorded using a handheld GPS (Garmin eTrex 30, Kansas, USA). All work was
130 approved by a University of Queensland Animal Ethics Committee (permit #SBS/352/EHP/URG)
131 and conducted under Queensland Government National parks scientific permit #
132 WITK15315614.

133

134 Tracking plots

135 Tracking plots were used to estimate relative activity of predators during the peak sea turtle
136 nesting time (December – March) across two consecutive years. In 2015-2016, these plots were
137 also monitored for four days in April, a time when most sea turtle clutches had finished
138 hatching. Twenty-one tracking plots (2 m x 1 m) in 2014-2015 and 41 in 2015-2016, spaced 100
139 m apart, were set up on the primary dune (where most sea turtle nests were constructed). The
140 plots extended along the dunes for 1 km (2014-2015) and 2 km (2015-2016) north and south of
141 Wreck Rock camping area. The monitored area of a plot was marked by sticks placed at each
142 corner of the plot and the plot's location was recorded with a handheld GPS. Each plot was
143 inspected daily during the afternoon (weather permitting), and the number of goanna and fox
144 tracks recorded. After reading, plots were resurfaced using a rake to obliterate tracks, insuring
145 the same tracks were not recorded on subsequent days. The activity of predators was
146 quantified using the passive activity index (PAI) of Engeman *et al.* (1998):

147
$$PAI = \frac{1}{d} \sum_{j=1}^d \frac{1}{P_j} \sum_{i=1}^{P_j} X_{ij}$$

148 where the X_{ij} value represents the number of tracking plot tracks by an observed species at the
149 i th plot on the j th day; d is the number of days of inspection, and P_j is the number of plots
150 contributing data on the j th day. PAI was calculated for each day throughout the study for
151 statistical comparisons, and at 10 day intervals for graphical presentation of data.

152

153 Nest monitoring

154 Once a nest was located it was visited daily throughout the incubation period in order to
155 identify predation events and the tracks of animals visiting nests. Each nest was inspected
156 during the morning (weather permitting) and the number of goanna and fox tracks was
157 recorded. Nest area approximately 1m^2 was resurfaced by using a rake after observation. Nest
158 visitation rate was quantified as a percentage by dividing the number of days fresh tracks were
159 found at a nest by the total number of nest inspection days (nest inspection days = total
160 number of times a nest was inspected during the season until hatchlings emerged from the nest
161 or until it was totally predated) multiplied by 100.

162

163 Camera traps

164 Camera traps (Reconyx Hyperfire HC600, Holmen, Wisconsin, USA) were set up to capture
165 images of predators visiting a sample of 12 loggerhead turtle nests (randomly selected)
166 between 6 December 2014 and 27 January 2015 and 30 nests (randomly selected) between 1
167 December 2015 and 27 February 2016. Camera traps were at each nest for 25 days in 2014-

168 2015 and 30 days in 2015-2016. All camera traps were triggered by motion sensors and could
169 be triggered 24 hours per day. Camera traps were positioned 50 cm behind the selected turtle
170 nests, at least 30 cm above ground. Each camera trap had a 1 m² field of view over the nest
171 insuring that any nest visitation by predators was recorded. This enabled information on the
172 frequency, time of day and species to be collected. To compare the relative activity of goannas
173 visiting nests each year with PAI and nest predation rates between years, we calculated the
174 nest visitation rate (%) for camera trap monitored nests. Camera trap visitation rate was
175 defined as 100 times the number of independent images (defined as taken at least 20 minutes
176 apart; multiple images taken within 20 minutes of each other were classified as a single
177 visitation event) of goannas recorded at nests divided by the number of camera trap days. The
178 number of camera trap days each season was calculated as the total number of days each nest
179 was monitored in a season for all nests monitored in a season. 

180

181 Results

182 Tracking plots

183 Monitored tracking plots revealed tracks of two potential egg predators, goannas (lace
184 monitors and yellow-spotted goannas combined as it was not possible to distinguish between
185 the two species on the basis of their tracks alone) and red foxes. Only a few dog tracks were
186 identified in tracking plots during the course of the study. However, these dog tracks were most
187 likely made by pet dogs accompanying tourists visiting the beach, and so have been excluded
188 from analysis.

189

190 In both the 2014-2015 and 2015-2016 nesting seasons, the number of tracking plot-days with
191 recorded goanna activity (n=466 in 2014-2015; n=535 in 2015-2016) was approximately eight
192 times greater than fox activity (n=62 in 2014-2015; n=70 in 2015-2016) (2014-2015 goanna
193 mean daily PAI was 0.31 ± 0.21 (mean \pm SD), fox PAI 0.04 ± 0.07 ; 2015-2016 goanna mean daily
194 PAI was 0.16 ± 0.1 , fox 0.02 ± 0.03). Both goanna and fox activity (PAI) on the dune were
195 greater in 2014-2015 than in 2015-2016 (Students T-test: goanna: $P < 0.01$; fox: $P = 0.036$) and
196 goanna activity was significantly greater than fox activity in both years (Students T-Test: 2014-
197 2015, $P < 0.01$; 2015-2016, $P < 0.01$). During the 2014-2015 season, goanna activity on the dune
198 front remained relatively constant throughout the season (Fig. 2). Fox activity was generally
199 much lower than goanna activity from December through January, but there was a conspicuous
200 increase in fox activity in February (Fig. 2). In the 2015-2016 nesting season, goanna activity was
201 relatively low in December, increased during January and February and decreased again at the
202 end of February and was lowest in April at a time when most sea turtle nests had hatched. Fox
203 activity remained low and relatively constant throughout the entire season (Fig. 2). Goanna
204 activity was twice as great during the 2014-2015 sea turtle nesting season as during the 2015-
205 2016 season (Fig. 2).

206

207 Nest monitoring

208 During the first sea turtle nesting season (5/12/2014 until 4/3/2015), 52 loggerhead turtle nests
209 were monitored, and 57.7% of these nests were predated by goannas as indicated by burrows

210 constructed into the nest egg chamber. During the second nesting season (7/12/2015 until
211 28/2/2016), 46 nests were monitored, and 17.4% of these nests were predated by goannas. No
212 fox or other predators were observed to raid turtle nest in either season. During the 2014-2015
213 nesting season, 520 goanna nest visits (lace monitors and yellow-spotted goannas combined as
214 it was not possible to distinguish between the two species on the basis of their tracks alone) as
215 evidenced by their tracks were recorded, with an average daily visitation rate of mean \pm SD 26.8
216 \pm 17.4% (n=52). Three hundred and forty-three nest visitation events were recorded in the
217 2015-2016 nesting season, with a daily visitation rate of $14.1 \pm 9.7\%$ (n=46), which is significant
218 lower **compare to** 2014 – 2015 (**P<0.01**). Nests that were predated could be dug open for the
219 first time at any time during the incubation period; there was no trend for the first nest attack
220 to be associated with nest construction or nest hatching (Fig. 3).

221

222 Camera traps

223 Images from camera traps showed that goannas were the only predators to visit monitored
224 nests; no images of foxes or wild dogs were recorded. All of the monitored nests had at least
225 one image of a goanna visit during the deployment period, with 55 nest visitation events being
226 recorded in the 2014-2015 nesting season (Table 1), and an overall daily camera trap visitation
227 rate of $18.3\% \pm 29.1$ (n=12). Forty-seven (85.5%) of these visitation events were made by
228 yellow-spotted goannas and only 8 (14.5%) were made by lace monitors. Despite all camera
229 traps being deployed by 20 December 2014, only two goannas appeared at nests in December
230 2014, but activity at nests increased sharply from the beginning of January 2015 (Fig. 4a). Eggs

231 were seen to be consumed on 17 occasions (14 yellow-spotted goannas, 3 lace monitors).
232 Yellow-spotted goannas were seen to open a nest for the first time on 17 occasions, but lace
233 monitors were only ever seen to visit nests that had already been opened. In the 2015-2016
234 nesting season, 107 goanna nest visiting events were captured (Table 1), with a daily camera
235 trap visitation rate of $11.9 \pm 13.3\%$ ($n=30$). Camera traps captured 87 yellow-spotted goanna
236 (81.3%) and 20 lace monitor (18.7%) events (Fig. 4b). Eggs were seen to be predated by yellow-
237 spotted goanna on 6 occasions. No lace monitors were seen consuming eggs in this season. In
238 both seasons, large adult yellow-spotted goannas were seen to open turtle nests, but no
239 images of yellow-spotted goanna hatchling or sub-adults visiting turtle nests were recorded.
240 There was no significant difference ($P= 0.50$) in overall daily camera trap visitation rate between
241 the two seasons.

242

243 Goannas visited nests at any time of the day between 8:00 and 18:00 (Fig. 4). Combining data
244 from both seasons, and plotting the data separately for yellow-spotted goannas and lace
245 monitors revealed that yellow-spotted goannas had a bi-modal nest visitation pattern (visiting
246 nests in the morning 7:00 – 11:00 and again in the afternoon 13:00 – 16:00), while the most
247 frequent time for visits from lace monitors was in the afternoon (15:00 – 17:00) (Fig. 5). A
248 **student's T-test** ($P < 0.001$) confirmed that the mean time of lace monitor visits (13:31 \pm 0.02,
249 $n=28$) was later than yellow-spotted goanna visits (11:28 \pm 0.02, $n=128$). An entire nest opening
250 sequence was recorded on 23-01-2015. A large yellow-spotted goanna first began digging at
251 14:12 (Fig 6a). It reached the egg chamber and consumed the first egg at 14:28 after 16 minutes

252 of continuous digging activity (Fig 6b). Turtle eggs were swallowed intact, one at a time, by the
253 goanna rather than being opened and having their contents licked out (Fig 6c). This goanna
254 stopped feeding and left the nest at 16:56 after almost 2.5 hours of feeding and having
255 consumed approximately eight eggs.

256

257 Discussion

258 Nest predation decreases the recruitment of hatchlings and has become an important challenge
259 for the conservation of egg-laying reptiles (Leighton *et al.* 2010). Hence, understanding the
260 activity of predators adjacent to endangered reptilian species breeding aggregations is
261 important for designing conservation strategies. The daily checking for predator tracks on nests
262 and the deployment of tracking plots and camera traps allowed us to continuously monitor
263 activities of nest predators adjacent to a loggerhead turtle nesting beach. There were two
264 significant results from the study that provide new insights into goanna predation of sea turtle
265 nests. First, camera trap data indicated that yellow-spotted goannas are the most frequent
266 visitors and predators of sea turtle nests at Wreck Rock beach and were the only species
267 observed to open nests, suggesting they are the main cause of nest predation. Second, the nest
268 predation rate and activity of goannas on the nesting dune varied by a factor of two between
269 the two seasons that we studied.

270

271 Predator activities at nests

272 Camera traps allowed us to explore the loggerhead turtle nest predator species, predation time

273 and behavior of predators while at nests. Yellow-spotted goannas were the most frequent
274 visitors and predators of sea turtle nests in this study. Large adult yellow-spotted goannas have
275 the ability to dig up sea turtle nests and swallow turtle eggs intact, suggesting future
276 management strategies should be targeted at these individuals. Indeed, no lace monitors were
277 observed to open sea turtle nests directly. They were only observed predated nests that had
278 already been opened by yellow-spotted goannas. Hence, lace monitors appear to be
279 opportunistic nest predators on this beach. Lace monitors are frequently arboreal and are
280 equipped with long, recurved claws that facilitate climbing (Cogger 1993). Such claws are not
281 particularly useful for digging and may explain why they did not open nests. Using GPS tracking
282 methodology, Lei & Booth (2015) reported yellow-spotted goannas use the beach dunes more
283 than lace monitors and are therefore more likely to predate sea turtle nests than lace monitors.
284 Hence, it appears that yellow-spotted goannas, in particular the large male individuals that
285 open up nests, make the nest available for predation by opportunistic lace monitors. Moreover,
286 camera traps did not record foxes at nests, and no fox tracks were observed over nests during
287 this study indicating that the fox baiting program deployed by park managers is currently
288 effective at inhibiting fox predation of sea turtle nests at Wreck Rock beach.

289

290 Although camera trap records indicated that sea turtle nests were visited by yellow-spotted
291 goannas at any time of day between 7:00 and 17:30, visits were most frequent in the morning
292 and afternoon with a distinct lull during the middle of the day. This reflects the general activity
293 pattern of yellow-spotted goannas as recorded by GPS tracking data (Lei and Booth,

294 unpublished). It would appear that the midday heat suppresses the foraging activity of yellow-
295 spotted goannas, and this may be particularly so in the beach dune area there are no trees to
296 provide shade. In contrast, although the data is far less numerous, lace monitors had a single
297 peak in sea turtle nest visiting activity, and this was late in the afternoon, typically after the
298 peak afternoon yellow-spotted goanna nest visiting time. Hence, lace monitors may arrange
299 their nest visiting times to avoid interacting with yellow-spotted goannas. Further investigation
300 of this possibility is needed.

301

302 Doody *et al.* (2014, 2015) reported that yellow-spotted goannas can dig warren complexes that
303 required removal of sand from up to 3 m deep and that both males and females contribute to
304 warren excavation. Hence, the job of digging into a sea turtle nest which is comparatively
305 shallow (40 - 80 cm), should be relatively easy as evidenced by it requiring only 16 minutes of
306 digging to gain access to eggs in one of our monitored nests. Our camera trap images indicated
307 that yellow-spotted goannas normally dug into the nest at an angle from one side of the nest to
308 reach the nest chamber rather than digging a hole vertically downwards from directly above
309 the nest. Hence, when covering a nest with mesh as a management strategy used to deter nest
310 predation, the mesh must be relatively large in area (at least 1 x 1 m) to prevent yellow-spotted
311 goanna burrowing into the nest (Lei & Booth 2017). Turtle nest predation rate is likely
312 dependent on cues left by the female turtle (e.g. visual, tactile, and olfactory), and many
313 predators have the ability to detect these cues (Vander Wall 1998, 2000; Geluso 2005; Leighton
314 *et al.* 2009). Goannas use their forked tongue to transfer olfactory cues to the specialized

315 chemosensory Jacobson's organ and so are adept at using olfactory cues to find prey (Blamires
316 & Guinea 1998; King & Green 1999; Vincent & Wilson 1999). In addition, goannas are skilled at
317 detecting prey cues which enhance their foraging strategies (King & Green 1999). We found
318 that once a turtle nest was opened, this nest was continually predated over subsequent days by
319 multiple yellow-spotted goannas.

320

321 We suspected that goannas might attack sea turtle nests more frequently immediately after
322 their construction, or after hatching at the end of incubation. These expectations were based
323 on the idea that sand disturbance and the smell of the female and or newly laid eggs around
324 the sand might give clear clues to foraging goannas immediately after nest construction, and
325 that the smell of egg fluids released during the hatching process might also attract goannas at
326 the end of incubation. This was not what we observed; a nest was equally likely to be attacked
327 for the first time at any time during incubation. We do not know why this is the case,
328 particularly as goannas crawled over the top of some nests several times during incubation
329 without attacking them, and then at a later date these nests were attacked. One possibility
330 might be that ghost crabs (*Ocypode ceratophthalmus* and *O. cordimanus*) which are numerous
331 on the nesting beach and frequently burrow into sea turtle nests, cause the release of
332 'incubating egg odor' which then attracts goannas.

333

334 Predator activity

335 Based on the PAI analysis of tracking plot data, the activity of goannas was higher than that of

336 foxes, suggesting that goannas are the main predator of sea turtle nests at Wreck Rock beach, a
337 conclusion also supported by nest track and camera trap data. We found that all of our
338 monitored nests were visited by goannas and that between 17% (2015-2016) and 58 % (2014-
339 2015) of nests were opened by yellow-spotted goannas. Goanna predation of nests had
340 previously been reported as greater than 50% at this beach (McLachlan *et al.* 2015). It is unclear
341 whether goanna predation of sea turtle nests was this high at Wreck Rock beach during pre-
342 European settlement times or whether more recent perturbations have led to increased nest
343 predation in relatively recent times. During the 1970s-1990s goanna predation of sea turtle
344 nests at this location was not detected, but fox predation of nests was high, 90% of nests being
345 predated in the 1970's and up until 1987 (Limpus 2008). From 1987 onwards, a fox baiting
346 program reduced fox predation on sea turtle nests to negligible levels (Limpus 2008). Goanna
347 predation of sea turtle nests was first reported in the 2003-2004 nesting season when two
348 nests were predated (Limpus 2008), and since then goanna predation of sea turtle nests has
349 increased so that over 50% of sea turtle nests were being attacked by goannas in the 2013-2014
350 season (McLachlan *et al.* 2015). Hence, the reduction in red fox numbers may have also
351 resulted in an increased recruitment of yellow-spotted goannas (because red foxes probably
352 also predated yellow-spotted goanna nests) to historically high levels. However, before
353 European settlement and the introduction of foxes, hunting of goannas by native people may
354 have kept the density of goannas on the frontal dunes at a low level.

355

356 Goanna activity in 2014-2015 was twice as high as in the 2015-2016 nesting season, as was the

357 nest predation rate. This suggests that nest predation is positively correlated with goanna
358 activity. Maulany (2012) reported that olive ridley turtle nests suffered 100% predation by
359 monitor lizards at a beach adjacent to Alas Purwo National Park, Banyuwangi (East Java),
360 Indonesia, which had high monitor lizard activity (PAI = 1.27 in 2009, 1.41 in 2010). This finding
361 also suggests that goanna activity on dunes is a good predictor of intensity of goanna predation
362 on sea turtle nests.

363

364 Fox activity increased at the end of the 2014-2015 nesting season. Typically the park managers
365 fox bait twice during the sea turtle nesting season, once in early December and again in early
366 February. In 2014-2015 the February baiting was missed, so any foxes that might have moved
367 into the beach area after the December baiting were not removed. However, in the 2015-2016
368 season, the early February fox baiting probably maintained fox activity at low levels.

369

370 The goanna predation rate of sea turtle nests in 2014-2015 was twice that in 2015-2016, and it
371 correlated with an increase in goanna activity on the dune. The nest visitation rate by recording
372 tracks in 2014-2015 was nearly twice that in 2015-2016. In addition, nest visitation rate from
373 camera traps in 2014-2015 (18.3%) was higher than 2015-2016 (11.8%) nesting season. These
374 results suggested goanna activity on the dune in 2014-2015 was higher than in 2015-2016.
375 However, it remains unclear why goanna activity and sea turtle nest predation rate varied so
376 greatly between the two nesting seasons. Because of the strong inter-annual differences in
377 predator indices over two years, additional years of research are needed to determine the long-

378 term average predation rate and its implications for turtle hatching success.

379

380 Implications for management

381 Lei & Booth (2017) compared different methods of directly protecting sea turtle nests against
382 goanna predation and found that deploying the plastic mesh on the top of turtle nests was the
383 most effective and economic way. Combined with our observations of digging behaviour of
384 yellow-spotted goanna captured on camera traps, we suggested that plastic mesh needs to be
385 at least 1 x 1m to prevent yellow-spotted goannas digging into the nest chamber. In addition,
386 camera trap data indicated turtle nest predation activities happen any time between 7:00 and
387 17:00, suggesting turtle nest management should be deployed in the early morning following
388 the night that nests are constructed. More management strategies such as temporary removal
389 of large male yellow-spotted goannas or egg relocation should be investigated in the future to
390 counteract the loss of sea turtle nests to yellow-spotted goanna predation.
