*Homonota* is a Neotropical genus of nocturnal lizards characterized by the following combination of characters: absence of femoral pores, infradigital lamellae not dilated, claws without sheath, inferior lamellae laterally not denticulate, and presence of a ceratobranchial groove. Currently the genus is composed of 10 species assembled in three groups: two groups with four species, and the *fasciata* group with only two species. Here, we analyzed genetic and morphologic data of samples of *Homonota fasciata* from Paraguay; according to Maximum Likelihood and Bayesian inference analyses, the Paraguay population represents an undescribed species. Additionally, morphological analysis of the holotype of *H. fasciata* (MNHN 6756) shows that it is morphologically different from the banded, large-scaled *Homonota* commonly referred to as "*H. fasciata*". Given the inconsistency between morphological characters of the name-bearing type of *H. fasciata* and the species commonly referred to as *H. fasciata*, we consider them as different taxa. Thus, *H. fasciata* is a *species inquirenda* which needs further studies, and we resurrect the name *H. horrida* for the banded, large-scaled *Homonota*. The undescribed species from Paraguay is similar to *H. horrida*, but can be differentiated by the high position of the auditory meatus relative to the mouth commissure (vs. low position in *H. horrida*); and less developed tubercles on the sides of the head, including a narrow area between the orbit and the auditory meatus covered with small granular scales with or without few tubercles (vs. several big tubercles on the sides of the head even in the area between the orbit and the auditory meatus). The new species is distributed in the Dry Chaco in South America. With the formal description of this species, the actual diversity of

the genus *Homonota* is increased to 12 species. Furthermore, we infer phylogenetic relationships for 11 of the 12 described species of the genus, based on 11 molecular markers (2 mitochondrial and 9 nuclear genes), with concatenated and species tree approaches.

21 **Abstract**

22 *Homonota* is a Neotropical genus of nocturnal lizards characterized by the following  
23 combination of characters: absence of femoral pores, infradigital lamellae not dilated, claws  
24 without sheath, inferior lamellae laterally not denticulate, and presence of a ceratobranchial  
25 groove. Currently the genus is composed of 10 species assembled in three groups: two groups  
26 with four species, and the *fasciata* group with only two species. Here, we analyzed genetic and  
27 morphologic data of samples of *Homonota fasciata* from Paraguay. According to Maximum  
28 Likelihood and Bayesian inference methods applied to species delimitation and phylogenetic  
29 analyses, the Paraguay population represents an undescribed species. Additionally,  
30 morphological analysis of the holotype of *H. fasciata* (MNHN 6756) shows that it is  
31 morphologically different from the banded, large-scaled *Homonota* commonly referred to as “*H.*

32 *fasciata*". Given the inconsistency between morphological characters of the name-bearing type  
33 of *H. fasciata* and the species commonly referred to as *H. fasciata*, we consider them as different  
34 taxa. Thus, *H. fasciata* is a *species inquirenda* which needs further studies, and we resurrect the  
35 name *H. horrida* for the banded, large-scaled *Homonota*. The undescribed species from Paraguay  
36 is similar to *H. horrida*, but can be differentiated by the high position of the auditory meatus  
37 relative to the mouth commissure (vs. low position in *H. horrida*); and less developed tubercles  
38 on the sides of the head, including a narrow area between the orbit and the auditory meatus  
39 covered with small granular scales with or without few tubercles (vs. several big tubercles on the  
40 sides of the head even in the area between the orbit and the auditory meatus). The new species is  
41 distributed in the Dry Chaco in South America. With the formal description of this species and  
42 the revalidation of *H. horrida*, the actual diversity of the genus *Homonota* is increased to 12  
43 species. Furthermore, we infer phylogenetic relationships for 11 of the 12 described species of  
44 the genus, based on 11 molecular markers (2 mitochondrial and 9 nuclear genes), with  
45 concatenated and species tree approaches.

46

47

## INTRODUCTION

48 The genus *Homonota* is a gecko of Gondwanan origin, distributed in South America, being  
49 present in southern Bolivia, northern to southern Argentina, western Paraguay, Uruguay, and the  
50 Brazilian state of Rio Grande do Sul (Gamble et al., 2008a; Morando et al., 2014). Along its  
51 distribution it inhabits dry environments like Monte, Chaco, Espinal, Patagonian, Andean, and  
52 Pampas (Morando et al., 2014). Regardless of the ecoregion, the genus is terrestrial and with the  
53 exception of *Homonota fasciata*, all species have a reticulated coloration pattern that imitates  
54 lichens on rocky backgrounds (Avila et al., 2012: Fig. 1). Unlike other geckos in South America,  
55 *Homonota* is adapted to a terrestrial life-style being only infrequently found in trees (Ceï, 1986).

56 All species in the genus are nocturnal, oviparous –laying one or two eggs–, insectivorous  
57 lizards that can be found frequently in human dwellings feeding on a wide range of arthropods  
58 (Ceï, 1986; Ceï, 1993; Abdala, 1997; Carreira et al., 2005; Ibarzüengoytía & Casalinas, 2007;  
59 Kun et al., 2010). Members of this genus are characterized by the following combination of  
60 characters: absence of femoral pores, infradigital lamellae not dilated, claws without sheath,  
61 inferior lamellae laterally not denticulate, and presence of a ceratobranchial groove (Peters &  
62 Donoso-Barros, 1970; Ceï, 1986; Carreira et al., 2005). Currently, ten species are recognized in

63 this genus (Cajade et al., 2013), some of which have small distribution ranges restricted to one or  
64 few localities (e.g., *H. andicola*, *H. rupicola*, *H. taragui*, and *H. williamsii*) or medium-sized  
65 distributions of less than 400 km from north to south (e.g., *H. uruguayensis* and *H. whitii*),  
66 whereas others have wide distribution ranges (e.g. *H. borellii*, *H. fasciata*, *H. underwoodi*, and  
67 *H. darwinii*) (Morando et al., 2014). In fact, *H. darwinii* reaches 50° S latitude, the southernmost  
68 limit for the genus and for any gecko species of the world.

69 Kluge (1964) proposed a grouping arrangement for *Homonota*, in which he placed *H.*  
70 *borellii*, *H. fasciata*, *H. horrida* (as a different species of *H. fasciata*), and *H. uruguayensis* in  
71 one group, and *H. darwinii*, *H. underwoodi*, and *H. whitii* in another. But a recent molecular  
72 analysis carried out by Morando et al. (2014) shows a different arrangement dividing the genus  
73 into three groups (i.e., the *borellii*, *whitii*, and *fasciata* groups). This last group is the least  
74 diverse with only two species, whereas each of the former two contain four species (Morando et  
75 al., 2014). The two species belonging to the *fasciata* group are *H. underwoodi* described by  
76 Kluge (1964) and *H. fasciata* with a complex taxonomic history discussed by Abdala & Lavilla  
77 (1993).

78 Duméril & Bibron (1836), based on a single specimen from “Martinique”, described  
79 *Gymnodactylus fasciatus*. Burmeister (1861) described *Gymnodactylus horridus* from Sierra del  
80 Challao, in Mendoza Province (Argentina). Gray (1845) erected the genus *Homonota* to  
81 accommodate the “Guidichaud’s Scaled Gecko” [sic] *Gymnodactylus gaudichaudii* Duméril &  
82 Bibron, 1836 (currently *Garthia gaudichaudii*), but according to Vanzolini (1968), Gray actually  
83 used a specimen of *Homonota darwinii* (and not *G. gaudichaudii*), for the description of  
84 *Homonota*, so that *Homonota darwinii* is the actual type species of the genus. In a brief  
85 publication, Berg (1895) provided a description of a lizard he named *Gymnodactylus*  
86 *mattogrossensis* from Mato Grosso (Brazil, without any specific locality data), referring to a  
87 single specimen (not vouchered) given to him by his colleague Julio Koslowsky. Kluge (1964)  
88 moved these three names to the genus *Homonota* recognizing *H. horrida* and *H. fasciatus* [sic] as  
89 a valid species and transferring *Gymnodactylus mattogrossensis* to the synonymy of *H. horrida*.  
90 Kluge (1964) stated that these species are similar but differ in the number of interorbital scales  
91 (10–14 in *H. horrida* vs. 16 in the holotype of *H. fasciata*), the denticulation of ear opening  
92 (strongly denticulate all around the opening in *H. horrida* vs. a slight denticulation on the  
93 anterior margin in *H. fasciata*), size of postmental scales (moderately enlarged in *H. horrida* vs.

94 greatly enlarged in *H. fasciata*), and size and shape of gular scales (large and plate-like in *H.*  
95 *horrida* vs. small and granular in *H. fasciata*). According to this author, *H. horrida* is present in  
96 southern Bolivia and Brazil, Paraguay, and northwestern Argentina, whereas the distribution of  
97 *H. fasciata* is unknown because its type locality “Martinique” is apparently based on a mistake,  
98 and no more additional locality records were available. Abdala & Lavilla (1993) suggested that  
99 diagnostic characters between *H. horrida* and *H. fasciata* as proposed by Kluge (1964) were  
100 intraspecific variation, and they synonymized *H. horrida* with *H. fasciata*. Since then the name  
101 *H. fasciata* was applied to the banded, large-scaled *Homonota* distributed from northern  
102 Paraguay and southern Bolivia, to Río Negro Province (central Argentina).

103 An almost complete molecular phylogenetic analysis was performed by Morando et al.  
104 (2014) including topotypes of all the recognized species. For *H. fasciata* the authors used  
105 specimens from Mendoza, since the original type locality (Martinique) is a mistake, and Abdala  
106 & Lavilla (1993) restricted the type locality of *H. fasciata* to Mendoza (in den Schluchten der  
107 Sierra bei Challao), which is actually the type locality for *Homonota horrida*.

108 In Paraguay, *Homonota fasciata* is distributed mainly in the Dry Chaco, with only one  
109 record in a transition zone of Dry Chaco with Humid Chaco (Cacciali et al., 2016). Given that *H.*  
110 *fasciata* has a complex taxonomic history, is one of the widest distributed members of the genus,  
111 and the almost complete absence of samples from Paraguay in previous publications, here we  
112 follow an integrative approach to assess the taxonomic status of samples from this country. First,  
113 within the framework of a barcoding project of Paraguayan herpetofauna, we generated  
114 molecular data and inferred a first round of hypotheses. Second, based on 11 genes, we inferred  
115 the taxonomic position of the Paraguayan populations in a phylogenetic tree that includes all the  
116 described species. Lastly, we analyzed detailed morphological data and also examined the  
117 holotype of *H. fasciata*.

118

119

## MATERIALS AND METHODS

### 120 Genetic analyses

121 We carried out a first genetic inspection of the taxonomic status of Paraguayan populations  
122 currently referred to as *Homonota fasciata* using sequences of the mtDNA 16S gene as it was  
123 proved to be a useful tool for taxonomic identification (Jansen & Schulze, 2012; Batista et al.,  
124 2014; Köhler et al., 2014) with a desirable relation of cost/benefit. The Paraguayan samples

125 (N=3, GenBank accession numbers presented in Appendix S1, Supplementary Information  
126 online) from two localities were compared with available samples of the species from Mendoza,  
127 Argentina (used by Morando et al., 2014) located ~1.400 km in straight line (N=3). Localities of  
128 vouchers used for genetic analyses are shown in Appendix S2. Paraguayan samples were  
129 collected with collecting permits SEAM N° 04/11 and SEAM N° 133/2015 issued by the  
130 Secretaría del Ambiente in Paraguay. Specimens were euthanized using anesthetic injections of  
131 barbituric acids (Tiopental Sódico® 1g).

132 Tissue samples were first washed for 15 h with 50 µl Phosphate-buffered saline (PBS)  
133 (diluted of 1:9 PBS: H<sub>2</sub>O). They were digested in a solution of Vertebrate lysis buffer (60 µl per  
134 sample) and proteinase K (6 µl per sample) at 56°C for 15 h. Protocol for DNA extraction  
135 followed Ivanova et al. (2006). After extraction, DNA was eluted in 50 µL Tris-EDTA (TE)  
136 buffer. Amplification of mtDNA 16S gene fragments was made using the eurofins MWG Operon  
137 primers L2510 (forward: 5'-CGCCTGTTTATCAAAAACAT-3') and H3056 (reverse: 5'-  
138 CCGGTCTGAACTCAGATCACGT-3') in an Eppendorf Mastercycler® pro. PCR conditions  
139 were: 94°C–2 min, 40× [94°C–35 s, 48.5°C–35 s, 72°C–1 min], 72°C–10 min. Sequencing was  
140 performed using a BigDye® Terminator with the following cycling conditions: 95°C–1 min, 30×  
141 [95°C–10 s, 50°C–10 s, 60°C–2 min], with 10 µl of reaction volume.

142 The examination of chromatograms and generation of consensus sequences was performed  
143 using SeqTrace 0.9.0 (Stucky, 2012). Sequences were aligned first automatically with Clustal W  
144 (Larkin et al., 2007) followed by a visual inspection and edition if necessary, with the freeware  
145 MEGA 6 (Tamura et al., 2013). The alignment and the tree are available at TreeBase (ID:  
146 20987). The substitution model for our dataset was identified according to the corrected (for  
147 finite sample size) Akaike Information Criterion (AICc) (Burnham & Anderson, 2002) and  
148 computed in MEGA 6.

149 We estimated the uncorrected genetic pairwise distances for our dataset, and ran Maximum  
150 Likelihood (ML) analysis with 30,000 bootstrap replicates in MEGA 6. We used *Phyllopezus*  
151 *przewalskii* as outgroup (SMF 100495, GenBank accession number pending), due to availability  
152 of relevant genetic information.

153 We used a species delimitation methods to assess the degree of intraspecific divergences  
154 and, to support the cluster arrangement suggested by the ML approach. This exploration was  
155 performed separately for the alignment and for the tree. The alignment was analyzed with ABGD

156 (Puillandre et al., 2012) using simple distances to compare with the uncorrected genetic distance.  
157 For the tree based on 16S analysis, we applied the Poisson tree process (PTP) (Zhang et al.,  
158 2013) conducted through the bPTP web Server (<http://species.h-its.org/>), using default  
159 parameters and the outgroup removed. This algorithm does not require an ultrametric tree as  
160 input (Zhang et al., 2013), and it is a robust tool to estimate species delimitation from ML  
161 phylogenetic reconstructions (Tang et al., 2014). To assess the phylogenetic position of the  
162 Paraguayan samples within the genus, we used data from the recently published phylogenetic  
163 inference by Morando et al. (2014) and generated new sequences for all markers for samples  
164 from Paraguay (Appendix S3). We followed Morando et al. (2014) for amplification of the same  
165 two mitochondrial and nine nuclear genes, alignment protocols and gene and species trees  
166 approaches. Primers are specified in Appendix S4.

167 Consensus sequences for each sample was generated with Sequencher v4.8 (<sup>TM</sup>Gene Codes  
168 Corporation Inc. 2007, Ann Arbor, MI, USA), and aligned with Mafft (Kato & Standley, 2013).  
169 Confirmation of open reading frames for protein-coding genes was made by translation into  
170 amino acids.

171 The best evolutionary substitution model for each gene was selected using the AICc  
172 (Burnham & Anderson, 2002) and ran in jModelTest v2.1.10 (Darriba et al., 2012).  
173 Recombination was tested and excluded for nuclear genes using RDP: Recombination Detection  
174 Program v3.44 (Martin & Rybicki, 2000; Heath et al., 2006). We conducted Separate Bayesian  
175 analyses (BI) for each gene using MrBayes v3.2.2 (Ronquist & Huelsenbeck, 2003). Four heated  
176 Markov chains (with default heating values) and run for five million generations were used for  
177 each analysis. The equilibrium samples (after 25% of burn-in) were used to generate a 50%  
178 majority-rule consensus tree, and posterior probabilities (PP) were considered significant when  
179  $\geq 0.95$  (Huelsenbeck & Ronquist, 2001). Maximum Likelihood (ML) analyses for each gene were  
180 performed with RAxML v7.0.4 (Stamatakis, 2006), based on 1000 rapid bootstrap analyses for  
181 the best ML tree.

182 We performed concatenated analyses with ML and BI for the following datasets: (1) two  
183 mitochondrial genes combined, (2) nine nuclear genes combined, (3) all genes combined.  
184 Likelihood analyses were performed using RAxML v7.0.4, based on 1000 rapid bootstrap  
185 analyses. Bayesian analyses were conducted using MrBayes v3.2.2, with four heated Markov  
186 chains (using default heating values) and run for 50 million generations, with Markov chains

187 sampled at intervals of 1000 generations. Equilibrium samples (after 25% of burn-in) were used  
188 to generate a 50% majority-rule consensus tree, and posterior probabilities (PP) were considered  
189 significant when  $\geq 0.95$  (Huelsenbeck & Ronquist, 2001).

190 For construction of a species tree incorporating the multispecies coalescent approach, we  
191 used the hierarchical Bayesian model integrated in \*Beast v1.8.0 (Drummond & Rambaut,  
192 2007). For all genes were run two separate analyses for 100 million generations (sampled every  
193 1000 generations). Clades with  $PP > 0.95$  were considered strongly supported.

194 To ensure that convergence was reached before default program burn-in values, we  
195 evaluated convergence of Bayesian MCMC phylogenetic analyses (MrBayes and \*Beast) by  
196 examining likelihood and parameter estimates over time in Tracer v1.6 (Rambaut et al., 2009).  
197 All parameters were between 157 and 23400 effective sample sizes (ESS).

198 All alignments and trees were stored in TreeBase (ID: 20987); phylip files produced by  
199 RAxML were converted to nexus with ALTER (Glez-Peña et al., 2010), and trees merged with  
200 matrices in Mesquite v3.2 (Madison & Madison, 2017).

201

## 202 **Morphological Approach**

203 Voucher specimens are listed in Appendix S5. Coordinates are presented in decimal degrees  
204 and WGS 84 datum, and all the elevations are in meters above sea level (masl). Institution codes  
205 follow Sabaj Pérez (2014).

206 Metric characters were taken following Avila et al. (2012), and include snout–vent length  
207 (SVL) from tip of snout to vent; trunk length (TrL) distance from axilla to groin from posterior  
208 edge of forelimb insertion to anterior edge of hindlimb insertion; foot length (FL) from tip of  
209 claws of the 4<sup>th</sup> toe to heel; tibial length (TL) greatest length of tibia, from knee to heel; arm  
210 length (AL) from tip of claws of the 3<sup>rd</sup> finger to elbow; head length (HL) distance between  
211 anterior edge of auditory meatus and snout tip; head width (HW) taken at level of the temporal  
212 region; head height (HH) maximum height of head, at level of parietal area; eye–nostril distance  
213 (END) from the anterior edge of the eye to the posterior edge of the nostril; eye–snout distance  
214 (ESD) from the anterior edge of the eye to the tip of the snout; eye–meatus distance (EMD) from  
215 the posterior edge of the eye to the anterior border of the ear opening; interorbital distance (ID)  
216 interorbital shortest distance; internostril distance (IND). Meristic data consist of: number of  
217 keeled dorsal tubercles (DT) from occipital area to cloaca level; number of transversal rows of

218 ventral scales (TVS), counted longitudinally at midline from the chest (shoulder level) to  
219 inguinal level; number of longitudinal rows of ventral scales (LVS), counted transversally at  
220 midbody; number of supralabial scales (SL); number of infralabial scales (IL); number of fourth  
221 toe lamellae (4TL); and number of third finger lamellae (3FL). Paired structures are presented in  
222 left/right order. In the color descriptions, the capitalized colors and the color codes (in  
223 parentheses) are those of Köhler (2012).

224 Based on the genetic clusters recognized by the barcoding analysis, we performed a  
225 discriminant function analysis (DA). As a first step we tested normality with Shapiro-Wilk (*W*)  
226 test (Shapiro et al., 1968; Zar, 1999). Then we performed the DA including variables with  
227 normal distribution, analyzing continuous characters (metrics) that are sensitive to ontogeny,  
228 separated from discrete (non-sensitive to body growth) characters. All statistical procedures were  
229 performed with Past 3.14 (Hammer et al., 2001).

230

231

## RESULTS

### 232 Phylogenetic inference

233 Following we present the size of each aligned gene (in brackets) and the best substitution  
234 model identified: 16S [527 bp]: GTR+G; 12S [951 bp]: GTR+G; cyt-b [794 bp]: TRN+I+G;  
235 MXRA5 [961 bp]: TPM1lf+G, NKTR [1074 bp]: TRN+G, SINCAIP [449 bp]: TPM2 lf+G,  
236 RBMX [600 bp]: HKY+G, DMXL1 [959 bp]: HKY+G, ACA4 [1218 bp]: HKY+G, PRLR [543  
237 bp]: TRN+G, Homo\_30b [664 bp]: TRN+I, Homo\_19b [642 bp]: F81+G.

238 The ML tree based on an initial exploration with 16S mtDNA gene sequences shows two  
239 separate clades of geckos, formerly referred to as *Homonota fasciata* (Fig. 1), with uncorrected  
240 16S p-distances ranging between 1.8 and 2.5% (Table 1). In the alignment we identified 11 fixed  
241 different sites between these clades (Table 2). We interpret the documented genetic differences  
242 as evidence for heterospecificity of these two clades. Thus, we recognize two potential species of  
243 geckos formerly referred to as *H. fasciata*: Species A (sampled in Low Monte ecoregion) and  
244 Species B (sampled in Dry Chaco, Paraguay).

245 The ABGD analysis for the 16S dataset resulted in the recognition of three groups (1-  
246 Species A, 2- Species B, 3- Outgroup) with a range of intraspecific genetic variation from 0.1 to  
247 0.77%; and two groups (1- *Homonota*, 2- Outgroup) with an intraspecific variation of 1.29%  
248 (Appendix S6). This is only slightly higher than the higher intraspecific distance between two of

249 our samples (p-distance=1.0% between LJAMM-CNP 10495 and LJAMM-CNP 10576; Table 1)  
250 of Species A, whereas the intraspecific distance among specimens of Species B (<0.01%). The  
251 PTP also proposed two different clades (both with ML and Bayesian algorithms) grouping  
252 separately Argentinean samples (Species A) and Paraguayan samples (Species B) (Appendix  
253 S7). Species A was inferred as the sister taxon of Species B in nine of the 11 independent gene  
254 trees obtained with both BI and ML (Appendix S8). Exceptions include: 1-the gene Homo\_30b  
255 (both with BI and ML), which infer Species B as sister of the clade Species A + *H. underwoodi*;  
256 2-DMXL1 inferred the *borelli* group as sister to Species A+Species B (both with BI and ML); 3-  
257 the gene SINCAIP (ML only) showed the groups *fasciata* and *whitii* nested together; 4- the gene  
258 NKTR with ML inferred *H. underwoodi* as a member of a different group (Appendix S8).

259 All phylogenies inferred from concatenated datasets of (1) two mitochondrial genes  
260 combined, (2) nine nuclear genes combined, (3) all genes combined with both BI and ML  
261 showed high support in recognizing Species B from Paraguay as a sister to Species B from  
262 Argentina, with *Homonota underwoodi* as sister to these two within the *fasciata* group  
263 (Appendix S9). The species tree inferred with \*Beast presents the same arrangement within the  
264 *fasciata* group as those inferred by BI and ML using concatenated datasets (Fig. 2).

265

### 266 **Morphological analyses**

267 All the continuous variables had normal distributions, but two discrete variables (SL and IL)  
268 did not (Table 3), thus, they were excluded from further morphological analysis. Convex hulls  
269 for metric variables show a significant discrimination between Species A and Species B, which  
270 support the cluster differentiation inferred from molecular data (Fig. 3). The most contributing  
271 variables were SVL and TrL for Axis 1 (Appendix S10). Sexual dimorphism was not recorded  
272 for Species A, whereas an evident sexual dimorphism in Species B was documented (Fig. 3).  
273 Nevertheless, the probability ellipse (confidence=95%) propose a high overlap, and females of  
274 Species B is the most different group (Fig. 3).

275 Regarding meristic data, sexual dimorphism is more pronounced in *H. fasciata* than in  
276 *Homonota* sp. "Paraguay" (Fig. 4). Raw data are available in Appendices S11 (metric variables)  
277 and S12 (meristic variables).

278

### 279 **Taxonomic implications**

280 We take the significant level of genetic differentiation between these two clusters of  
281 *Homonota* as evidence for the recognition of two different taxa. In order to correctly assign  
282 names to these two species, we examined the relevant primary types of the nominal taxa in this  
283 species complex. The holotype of *H. fasciata* is MNHN 6756 (LSID:  
284 urn:lsid:zoobank.org:act:14CDAB98-810F-43B3-8F16-B29C830AB80C). As mentioned above,  
285 the original type locality of *H. fasciata* was given as “Martinique” and is without doubt  
286 erroneous. A detailed analysis of MNHN 6756 (Fig. 5) revealed that it differs in pholidosis in  
287 several significant characters from the biological species currently referred to as *H. fasciata*  
288 (Table 4), such as margin of auditory meatus (Fig. 6), size of first infralabial scale (Fig. 7), and  
289 the arrangement of dorsal scales (Fig. 8). Given these differences in several taxonomically  
290 important scalation traits, there is no doubt that MNHN 6756 is not conspecific with the  
291 biological species currently referred to as *H. fasciata*. The scalation traits of MNHN 6756  
292 presented above resemble the external morphology of *Homonota uruguayensis* (Vaz-Ferreira &  
293 Sierra de Soriano, 1961). However, *H. uruguayensis* does not have transversal bands on the  
294 dorsum, and in the original description of *H. fasciata* transversal bands on the dorsum of the type  
295 specimen are mentioned. In its current state, the holotype of *H. fasciata* is completely bleached  
296 and does not show any trace of banding (Fig. 5). In conclusion, we cannot link the holotype of *H.*  
297 *fasciata* to any of the known populations of *Homonota* which renders this name a *species*  
298 *inquirenda* which needs further studies and cannot be linked to either Species A or Species B.  
299 Our examination of the lectotype of *H. horrida* (IZH-R 1) revealed that it is conspecific with our  
300 Species A which is supported by the fact that the Argentinian specimens used in our genetic  
301 analysis are from the general area of the type locality of *H. horrida*. We therefore resurrect it  
302 from synonymy with *H. fasciata* and apply it to our Species A. As mentioned above, the original  
303 description of *H. mattogrossensis* is very brief, does not provide a precise type locality (and no  
304 representative of the genus *Homonota* is known to occur in Brazil) and no type material or other  
305 voucher specimen is known. Therefore this name cannot be applied to any of the known  
306 populations of this genus and we consider *Homonota mattogrossensis* to constitute a *nomen*  
307 *dubium*.

308 No name is available for our Species B and we therefore describe it as a new species below,  
309 presenting also a species account and a redescription of *H. horrida*. The electronic version of this  
310 article in Portable Document Format (PDF) will represent a published work according to the

311 International Commission on Zoological Nomenclature (ICZN), and hence the new names  
312 contained in the electronic version are effectively published under that Code from the electronic  
313 edition alone. This published work and the nomenclatural acts it contains have been registered in  
314 ZooBank, the online registration system for the ICZN. The ZooBank LSIDs (Life Science  
315 Identifiers) can be resolved and the associated information viewed through any standard web  
316 browser by appending the LSID to the prefix <http://zoobank.org/>. The LSID for this publication  
317 is: [Pending]. The online version of this work is archived and available from the following digital  
318 repositories: PeerJ, PubMed Central and CLOCKSS.

319

320 ***Homonota horrida* (Burmeister, 1861) sp. reval.**

321 - *Gymnodactylus horridus* Burmeister 1861

322 *Type locality*: “in den Schluchten der Sierra bei Challao”, Mendoza, Argentina.

323 *Types*: Original description based on three syntypes. Lectotype (IZH-R 1, Fig. 9) and  
324 paralectotype (IZH-R 2) designation according to Müller (1941).

325 - *Wallsaurus horridus* comb. nov. Underwood 1954

326 - *Gymnodactylus pasteuri* nom. nov. Wermuth 1965

327 LSID: urn:lsid:zoobank.org:act:27FAE0B5-2E88-46C5-A296-F7BBE0B20AE6

328

329 *Diagnosis*: It is a large species of *Homonota* with a dark dorsal color (grey or brown) with a  
330 pattern of clear transversal bands connected with a vertebral stripe. Additionally, it is  
331 differentiated from any other *Homonota* by the large size and development of the keeled scales  
332 on the head (including laterals) and dorsum.

333

334 *Redescription of the lectotype (Fig. 9)*: Adult male, SVL 44 mm, TrL 19 mm, tail 49 mm,  
335 FL 8.0 mm, TL 8.5 mm, AL 12.0 mm, HL 11.1 mm, HW 8.5 mm, HH 6.3 mm, END 3.7 mm,  
336 ESD 4.6 mm, EMD 4.1 mm, ID 4.3 mm, IND 1.4 mm; rostral wider than high; nares surrounded  
337 by rostral, supranasal, two postnasals, and first SL; SL 9/9; one elongated tubercular scale on the  
338 mouth commissure; upper region of the muzzle covered by big homogeneous juxtaposed scales;  
339 upper surface of the head covered with medium-sized (smaller than those on the muzzle)  
340 homogeneous juxtaposed scales intermixed with small granules; superciliary scales imbricated,  
341 associated to spiny-like scales on the posterior half of the orbit; lateral sides of the head

342 heterogeneously covered profusely with large keeled tubercles and small granular (sometimes  
343 elongated) scales; auditory meatus oblique and with serrated edge, and one big scale on the upper  
344 border; IL 6/6; mental triangular; postmentals big (about twice the size of the following posterior  
345 scales) contacting the mental, the first IL, and a row of six posterior scales (the two centrals  
346 smaller); scales under the head reducing in size posteriorly; dorsolateral parts of the neck with  
347 granular juxtaposed scales mixed with tubercles; throat region covered by imbricated cycloid  
348 scales; dorsum covered with 16 strongly keeled scales separated by one or two small granular  
349 scales; ventral scales cycloid and imbricated arranged in 18 longitudinal rows at midbody;  
350 suprascapular, axillar, and inguinal regions surrounded by small imbricated granules; sides of  
351 cloacal opening with two to three conical tubercular scales; anterior and dorsal surfaces of limbs  
352 covered by imbricated scales, slightly keeled on the dorsal surface; posterior region of limbs  
353 covered by small juxtaposed granules; ventral surface of forelimbs with juxtaposed granules, and  
354 ventral surface of hind limbs with large imbricated scales; subdigital lamellae of hands starting  
355 from pollex were recorded as follows: 8/8 - 12/12 - 14/14 - 16/16 - 8/11; subdigital lamellae of  
356 feet starting from hallux were recorded as follow: 17/17 - 21/18 - 17/17 - 13/13 - 7/8; large  
357 imbricated keeled scales around the tail disposed in rings, separated by two to three series of  
358 small scales.

359

360 *Coloration in preservative of the lectotype:* The specimen is at least 147 years old, and  
361 coloration is faded in most parts of the animal. The whole body is basically Cream White (52)  
362 with vestiges of blotches on the scapular region, pre and postocular lines, and rings around the  
363 tail of Salmon Color (58).

364

365 *Variation:* (Based on specimens referred in Appendix S5) SVL 42–64 mm; TrL 16–29 mm  
366 (36.9–46.0% of SVL in females, 35.7–46.8% in males); FL 7–11 mm (9.5±0.30) in males, 8–12  
367 mm (10.4±0.41) in females; TL 8.3–11.4 mm (9.7±0.28) in males, 8.3–12.5 mm (10.4±0.35) in  
368 females; AL 11.9–14.7 mm (13.3±0.38) in males, 18.8–16.8 mm (13.5±0.48) in females; HL  
369 10.5–16.1 mm (12.5±0.73) in males, 9.8–14.6 mm (12.7±0.49) in females; HW 8.2–12.4 mm  
370 (65.2–85.5% of HL in females, 77.8–99.0% in males); HH 4.9–7.8 mm (44.0–62.2% of HL in  
371 females, 46.2–55.2% in males); END 2.9–5.0 mm (29.6–40.0% of HL in females, 29.9–34.1% in  
372 males); ESD 3.6–6.6 mm (36.7–46.7% of HL in females, 39.0–43.9% in males); EMD 4.2–6.5

373 mm (35.2–47.9% of HL in females, 38.5–41.9% in males); ID 3.8–5.8 mm (29.7–54.1% of HL  
374 in females, 31.7–42.8% in males); IND 1.2–2.3 mm (11.3–23.5% of HL in females, 12.5–17.1%  
375 in males); SL 7–9; one or two elongated tubercular scales on the mouth commissure; upper  
376 region of the muzzle usually flattened, rarely slightly convex (LJAMM-CNP 6520); auditory  
377 meatus with one large scale on the upper border; IL 6–8; 13–20 longitudinal rows of ventral  
378 scales at midbody.

379 The coloration pattern (lost in the type series) consist of a dark and clear reticulation on the  
380 dorsal surface of the head, a dark longitudinal stripe from the tip of the snout across the temporal  
381 region extending posteriorly and upwards reaching the nuchal region. Dorsal background color  
382 usually dark with whitish transversal bands connected with a vertebral stripe of the same color.  
383 Limbs with an irregular reticulation. Ventral region of head and body always immaculate clear.  
384 Tail with dark and clear rings that can be present only on the dorsal and lateral areas of the  
385 organ, or continued to the ventral surface. Some melanic specimens (LJAM-CNP 6532, 6968)  
386 lack the vertebral stripe, and the clear transversal bands are inconspicuous.

387

388 *Distribution:* As mentioned before, this is a species complex which needs further analyses.  
389 As currently recognized, this clade is distributed from the Argentinean Province of Rio Negro in  
390 southern Argentina, to the center of Paraguayan Chaco, according to Morando et al. (2014). Our  
391 analyzed samples came from Low Monte ecoregion in southern Argentina.

392

393 ***Homonota septentrionalis n. sp.***

394 LSID: [Registration pending](#)

395

396 *Holotype:* MNHNP 12238 (original field number PCS 200), adult female (Fig. 10), collected  
397 on 10 December 2014 by P. Cacciali, at Fortín Mayor Infante Rivarola (21.679° S, 62.401° W,  
398 277 masl), Boquerón Department, Paraguay.

399

400 *Paratypes:* MNHNP 2821, 9037–8, 9131, 11406\*, 11409\*, 11410, 11419, 11421, 11423  
401 (Parque Nacional Teniente Enciso, Boquerón Department, Paraguay; 21.209°S, 61.655°W, 253  
402 masl); MNHNP 11850, 11855, 11860, 11872, 11873\* (Cruce San Miguel, in front of Parque  
403 Nacional Teniente Enciso, Boquerón Department, Paraguay; 21.203°S, 61.662°W, 254 masl);

404 SMF 101984\* (topotype); SMF 29277 (Villamontes, Tarija Department, Bolivia; 21.266°S,  
405 63.451°W, 398 masl). Holotype and specimens marked with an asterisk (\*) were used for  
406 molecular analyses.

407

408 *Etymology*: The specific name *septentrionalis* is Latin, meaning “northern” and refers to the  
409 fact that this species has the northernmost distribution of all the *Homonota* species.

410

411 *Diagnosis*: This is the largest species of the genus (max. 65 mm SVL) with robust body,  
412 prominent keeled tubercles disposed in four to eight longitudinal rows, and coloration pattern of  
413 dark background with one vertebral and six or seven transversal clear bands. It can be  
414 distinguished from *H. andicola*, *H. whitii*, and *H. underwoodi* by the presence of strongly keeled  
415 dorsal scales (vs. smooth dorsal scales in *H. andicola*, *H. whitii*, and *H. underwoodi*), transversal  
416 clear bands on a darker dorsum (vs. reticulated pattern), and from *H. underwoodi* also by a lower  
417 number of 4TL (16–20) and 3FL (11–15) (vs. 20–25 and 15–17 respectively in *H. underwoodi*).  
418 From *H. borellii* and *H. rupicola* by the oblique shape of the auditory meatus (vs. round in *H.*  
419 *borellii* and *H. rupicola*), transversal clear bands on a darker dorsum (vs. reticulated pattern), and  
420 also from *H. borelli* by the presence of strongly keeled dorsal scales (vs. moderately keeled), and  
421 from *H. rupicola* by a higher number of 4TL (16–20) (vs. 14–15). From *H. darwinii* by the  
422 presence of strongly keeled dorsal scales (vs. smooth at least on the anterior part of the dorsum in  
423 *H. darwinii*), and by transversal clear bands on a darker dorsum (vs. reticulated pattern). From *H.*  
424 *rupicola* and *H. taragui* by the presence of enlarged keeled tubercles on the sides of the head  
425 behind the orbits (vs. homogeneous granular scales). From *H. uruguayensis* by a higher number  
426 of IL scales (6–7, vs. 4–5 in *H. uruguayensis*), by the coloration, and by the serrated edge of the  
427 auditory meatus (vs. smooth granular edge in *H. uruguayensis*). From *H. williamsii* by the  
428 presence of strongly keeled dorsal scales (vs. moderately keeled) and by transversal clear bands  
429 on a darker dorsum (vs. reticulated pattern). From *H. horrida* (the most similar species) by the  
430 high position of the auditory meatus relative to the mouth commissure (vs. lower position in *H.*  
431 *horrida*) (Fig. 11); less developed tubercles on the sides of the head, including a narrow area  
432 between the orbit and the auditory meatus covered with small granular scales with without or  
433 with few tubercles (vs. several big tubercles on the sides of the head even in the area between the  
434 orbit and the auditory meatus) (Fig. 11).

435

436 *Description of the holotype:* Adult female, SVL 60 mm, TrL 26 mm, tail broken near the  
437 base, FL 11.0 mm, TL 10.8 mm, AL 14.1 mm, HL 14.8 mm, HW 13.3 mm, HH 7.9 mm, END  
438 4.6 mm, ESD 6.6 mm, EMD 5.1 mm, ID 5.5 mm, IND 2.5 mm; rostral wide with a median  
439 groove at the upper half; nares surrounded by rostral (slight contact), supranasal, two postnasals,  
440 and first SL (slight contact); SL 9/8; two elongated tubercular scales on the mouth commissure;  
441 upper region of the muzzle slightly convex covered by big homogeneous juxtaposed scales;  
442 upper surface of the head covered with big homogeneous juxtaposed scales intermixed with  
443 small granules; superciliary scales imbricated forming a serrated edge, associated to spiny-like  
444 scales on the posterior half of the orbit; lateral sides of the head heterogeneously covered with  
445 large keeled tubercles and small granular (sometimes elongated) scales; auditory meatus oblique  
446 and with serrated edge, and two big scales on the upper border; IL 6/6; mental triangular;  
447 postmentals big (less than twice the size of the following posterior scales) contacting the mental,  
448 the first IL, and a row of six posterior scales (the two centrals smaller); scales under the head  
449 reducing in size posteriorly; dorsolateral parts of the neck with granular juxtaposed scales mixed  
450 with tubercles; throat region covered by imbricated cycloid scales; dorsum covered with eight  
451 strongly keeled scales separated by one or two small granular scales, except on the vertebral area  
452 where keeled scales are separated by four granules; ventral scales cycloid and imbricated  
453 arranged in 20 longitudinal rows at midbody; suprascapular, axillar, and inguinal regions and  
454 cloacal opening surrounded by small imbricated granules; anterior and dorsal surfaces of limbs  
455 covered by large imbricated scales, keeled on the dorsal surface; posterior region of limbs  
456 covered by small juxtaposed granules; ventral surface of forelimbs with juxtaposed granules, and  
457 ventral surface of hind limbs with large imbricated scales; subdigital lamellae of hands starting  
458 from pollex were recorded as follows: 7/8 - 12/10 - 13/14 - 13/13 - 12/10; subdigital lamellae of  
459 feet starting from hallux were recorded as follow: 13/13 - 18/18 - 15/14 - 12/12 - 10/10; large  
460 imbricated scales around the tail (stump) with the eight uppermost strongly keeled.

461

462 *Coloration in life:* Dorsal surface of head Grayish Horn Color (268) with groups of Dusky  
463 Brown (285) scales, irregularly mixed with Hair Brown (277) scales; posterior surface of the  
464 head with a curved Hair Brown (277) line interrupted by five groups of Dusky Brown (285)  
465 scales; upper lateral view of the head Grayish Horn Color (268), edged below by a thick Dusky

466 Brown (285) stripe from the muzzle (interrupted by the orbit) to the temporal region; supralabial  
467 and infralabial regions Smoky White (261) with irregular Raw Umber (280) suffusions on the 1<sup>st</sup>  
468 and 2<sup>nd</sup> SL and 1<sup>st</sup> to 5<sup>th</sup> IL; region between mouth commissure and shoulder Smoky White (261)  
469 with irregular Dusky Brown (285) speckles, edged above (bordering the upper edge of the ear  
470 opening) by an irregular Cream Yellow (82) stripe; ventral surface of the head Smoky White  
471 (261); dorsal ground color Dusky Brown (285), with a Light Straw Yellow (95) vertebral stripe,  
472 and five transversal Light Sulphur Yellow (93) lines; lateral parts of the body Cream Yellow (82)  
473 with irregular Dusky Brown (285) speckles; venter Smoky White (261); dorsal surface of limbs  
474 Cream Color (12) with irregular Dusky Brown (285) speckles on the forelimbs, and groups of  
475 Dusky Brown (285) scales (eventually forming short stripes) on the hind limbs; ventral surface  
476 of limbs Smoky White (261).

477

478 *Coloration in preservative:* Dorsal surface of head Drab (19) with groups of Vandyke  
479 Brown (282) scales; posterior surface of the head with a curved Vandyke Brown (282) line;  
480 upper lateral view of the head Smoke Gray (266), edged below by a thick Raw Umber (260)  
481 stripe from the muzzle (interrupted by the orbit) to the temporal region; supralabial and  
482 infralabial regions Cream White (52) with irregular Raw Umber (260) suffusions on the 1<sup>st</sup> and  
483 2<sup>nd</sup> SL and 1<sup>st</sup> to 5<sup>th</sup> IL; region between mouth commissure and shoulder Cream White (52) with  
484 irregular Raw Umber (260) speckles; ventral surface of the head Cream White (52); dorsal  
485 ground color Raw Umber (260), with a Beige (254) vertebral stripe, and five transversal Cream  
486 White (52) lines; lateral parts of the body Cream White (52) with irregular Raw Umber (260)  
487 speckles; venter Cream White (52); dorsal surface of limbs Beige (254) with irregular Sepia  
488 (279) speckles on the forelimbs, and groups of Sepia (279) scales (eventually forming short  
489 stripes) on the hind limbs; ventral surface of limbs Cream White (52).

490

491 *Variation:* SVL 37–65 mm; TrL 15–28 mm (43.3–48.2% of SVL in females, 38.3–48.8% in  
492 males); Tail length 47–63 mm (ratio SVL:Tail - 1:1 in one female, 1:1.18–1:1.22 in two males,  
493 and 1:1.17 in a juvenile of unknown sex); FL 8–9 mm (8.8±0.37) in males, 10–12 mm  
494 (11.2±0.83) in females; TL 7.2–9.8 mm (8.7±0.36) in males, 9.4–11.3 mm (10.5±0.81) in  
495 females; AL 10.2–13.1 mm (11.7±0.91) in males, 13.1–15.0 mm (14.1±0.76) in females; HL  
496 10.7–13.3 mm (11.8±0.38) in males, 12.9–17.3 mm (14.6±1.66) in females; HW 8.1–13.3 mm

497 (71.6–89.8% of HL in females, 75.7–84.4% in males); HH 5.8–8.6 mm (49.7–61.3% of HL in  
498 females, 54.1–61.4% in males); END 3.7–5.8 mm (31.9–37.9% of HL in females, 29.3–39.1% in  
499 males); ESD 3.6–6.8 mm (39.3–46.7% of HL in females, 31.6–45.9% in males); EMD 3.6–5.6  
500 mm (34.4–40.8% of HL in females, 33.0–38.6% in males); ID 3.7–5.5 mm (30.1–38.7% of HL  
501 in females, 33.0–38.3% in males); IND 1.4–2.5 mm (14.4–16.9% of HL in females, 12.3–18.8%  
502 in males); SL 6–9; one or two elongated tubercular scales on the mouth commissure; upper  
503 region of the muzzle slightly convex or flattened; auditory meatus with one or two big scales on  
504 the upper border; IL 6–7; 12–20 longitudinal rows of ventral scales at midbody.

505 The coloration variation follows the same pattern observed for the holotype. Smaller animals  
506 (MNHNP 11419, 11423) are clearer and the clear transversal bands are reduced to the  
507 paravertebral area; vertebral stripe reduced in MNHNP 11855; three paratypes (MNHNP 2821,  
508 9037, 9131) have a darker pattern being reddish dorsal background color, and in two of them  
509 (MNHNP 2821, 9131) the transversal bands are almost faded; the original tail (MNHNP 9131,  
510 11419, 11421, 11850, 11860, 11872, SMF 29277) has transversal dark and clear bands dorsally,  
511 and clear or reddish hue ventrally.

512

513 *Distribution:* *Homonota septentrionalis* is distributed in the northernmost range of the genus.  
514 The examined specimens come from the Dry Chaco, at the westernmost part of the Paraguayan  
515 Chaco and southeast of Bolivia (Fig. 12).

516

517 *Habitat:* The environment inhabited by *H. septentrionalis* is a xerophytic (precipitation  
518 varies between 300 and 400 mm per year) and thorny dry forest, with null or scarce herbaceous  
519 stratum (Fig. 13). This species is a nocturnal ground dweller, being abundant in natural areas,  
520 and also present in anthropogenically modified areas.

521

522

## DISCUSSION

523 The analysis of genetic barcodes of the mtDNA gene 16S provided the first evidence for the  
524 existence of an undescribed species of *Homonota* in Paraguay, which was posteriorly tested with  
525 additional data. The uncorrected genetic distance of the 16S fragment between *H. horrida* and *H.*  
526 *septentrionalis* is rather low (1.8–2.5%) compared to distances between species of other genera  
527 of geckos such as *Diplodactylus* (4–12%; Pepper et al., 2006), *Phyllopezus* (6–15%; Gamble et

528 al., 2012), and *Lepidoblepharis* (12–23%; Batista et al., 2015). Using the species delimitation  
529 program ABGD, we estimated the intraspecific variation since this program explores the  
530 pairwise differences in barcode datasets, providing limits for intraspecific divergence (Puillandre  
531 et al., 2012). The expected intraspecific variation for *Homonota* Species A and Species B,  
532 matches with the variation in uncorrected pairwise distance (Table 1), with a clear difference  
533 between the two taxa. The tree-based PTP analysis provides speciation models based on number  
534 of substitution in a phylogenetic hypothesis, for which the branch length of a tree represents the  
535 number of substitutions (Zhang et al., 2013). This algorithm also suggested two putative species,  
536 one from Argentina (Species A) and the other from Paraguay (Species B).

537 The topology of the species tree (Fig. 2) shows *Phyllodactylus* as the sister genus of  
538 *Homonota*, congruent with Gamble et al. (2008b, 2011) and Morando et al. (2014). The  
539 arrangement among groups of *Homonota* inferred the *fasciata* group as the most basal clade, a  
540 hypothesis contrary to that proposed by Morando et al. (2014) where the *whitii* group was the  
541 most basal clade within *Homonota*. The majority of the topological arrangements among the  
542 concatenated trees are identical, with the exception of the position of *H. taragui* which was  
543 closely related to *H. rupicola* using mitochondrial genes, and related to *H. borellii* using nuclear  
544 genes (Appendix S9); a conflict that was already reported by Morando et al. (2014). In our  
545 phylogeny *H. horrida* and *H. septentrionalis* were inferred as sister taxa with high statistical  
546 support (PP=1, Fig. 2). Given the taxonomic modifications proposed here, we suggest referring  
547 to the group that contains *H. underwoodi*, *H. horrida*, and *H. septentrionalis* as the *H. horrida*  
548 species group.

549 The holotype of *Homonota fasciata* was sent to Paris by Auguste Plée who was a botanist  
550 who collected several samples of plants and animals in the Antilles, and some of his collections  
551 are valid records for Martinique (i.e., type locality of *H. fasciata*) such as *Monstera adansonii*  
552 (Alismatales: Araceae), *Auxis thazard* (Actinopterygii: Scombridae), *Eleutherodactylus*  
553 *martinicensis* (Amphibia: Eleutherodactylidae), *Mabuya mabouya* (Reptilia: Scincidae),  
554 *Megalomys desmarestii* (Mammalia: Cricetidae), whereas some others were recorded but  
555 currently extinct as *Leptodactylus fallax* (Amphibia: Leptodactylidae) and *Leiocephalus*  
556 *herminieri* (Reptilia: Leiocephalidae) (Madison, 1977; Collette & Aadland, 1996; Borroto-Páez  
557 & Ramos García, 2012; Hedges & Conn, 2012; Breuil, 2015). Thus, although some locality  
558 records provided by Plée are trustable, the name *H. fasciata* based on specimen MNHN 6756,

559 remains has to be considered as a *species inquirenda*. More historical analyses could shine some  
560 light on the real origin of this specimen.

561 Abdala & Lavilla (1993) stated that differences between *Homonota horrida* and the type of  
562 *H. fasciata* were due to variation, which is true for some meristic characters. Nevertheless, the  
563 small size of postmental scales and serrated edge of auditory meatus are common morphological  
564 traits of *H. horrida*. These authors suggested that some specimens of *H. horrida* could have big  
565 postmentals and smooth auditory meatus (referring to specimens FML 35 and FML 114) which  
566 is rare for the species. Another common trait for *H. horrida* is the presence of a tubercular scale  
567 on the upper edge of the auditory meatus, which is absent in the type of *H. fasciata*. Further  
568 genetic and morphological analyses of Argentinean populations of *H. horrida* are required for a  
569 better understanding of variation within the species.

570 *Homonota septentrionalis* is a large species of *Homonota*, with a marked sexual dimorphism  
571 in measurable characters according to the DA analysis (Fig. 3), where SVL and TrL are the  
572 variables that contribute more to the differentiation (Appendix S10). This differs from what is  
573 known for *Homonota darwinii* where Ibargüengoytía & Casalins (2007) found no sexual  
574 dimorphism, although Fitch (1981) reported differences in SVL between males and females in  
575 Gekkonidae with females usually larger than males. More analyses are needed in order to  
576 explore the extent of this pattern in other species of the genus.

577 Genetic analyses were key for the recognition of the new species, since the morphological  
578 differences between *H. septentrionalis* and *H. horrida* are subtle and they could be considered  
579 cryptic species. High degree of genetic differentiation and low degree of morphological  
580 distinction is a common phenomenon for lizards, leading to situations in which authors designate  
581 candidate species without formal descriptions (Gamble et al., 2012; Werneck et al., 2012), or  
582 cases in which authors base the entire diagnosis upon genetic clustering (Leaché & Fujita, 2010).

583 Currently, *Homonota septentrionalis* is known from the type locality (Fig. 11), in plain areas  
584 and xerophytic environments. Given the similarity in external morphology between *H.*  
585 *septentrionalis* and *H. horrida* it is difficult to elaborate a cresonymy list of the previous records  
586 for these species. Records published by Mendoza et al. (2015) as *H. fasciata* from Bolivia,  
587 probably are *H. septentrionalis*, but further morphological and genetic analyses are required for a  
588 better understanding of the distribution pattern of *H. septentrionalis*.

589 Based on these results, the actual diversity of the genus *Homonota* is as follows: *borellii*  
590 group: *H. borellii*, *H. uruguayensis*, *H. rupicola*, and *H. taragui*; *horrida* group: *H. horrida*, *H.*  
591 *underwoodi*, and *H. septentrionalis* sp. nov; *whitii* group: *H. whitii*, *H. darwinii*, *H. andicola*, and  
592 *H. williamsii*; *Incertae sedis*: *H. fasciata*.

593 Currently, the conservation status of *Homonota septentrionalis* is totally unknown.  
594 *Homonota fasciata* was categorized as Least Concern (LC) by Motte et al. (2009) given its big  
595 range, but since we actually do not know the range of *H. septentrionalis*, the conservation status  
596 might be different. This species is related to the Dry Chaco, which for a long time was a  
597 sanctuary for wildlife because of the lack of anthropogenic impacts; but unfortunately in the last  
598 decade the deforestation is severely threatening many areas of the Dry Chaco (Eva et al., 2004;  
599 Caballero et al., 2014). An assessment of the status of this new taxon is required.

600

601 **Acknowledgments:** We thank Emilio Buongermini, Ignacio Ávila, Norman Scott, and Aníbal  
602 Bogado for help during fieldwork. Also to Cristian Pérez (LJAMM-CNP), Nicolás Martínez  
603 (MNHNP), and Linda Mogk (SMF) for assistance during revision of specimens in scientific  
604 collections. We are grateful to the staff (especially Heike Kappes) of the Grunelius-Möllgaard  
605 Laboratory (SMF), and Joao Diogo (Lab Center, BiKF, SMF) for lab support, and to Diego  
606 Barrasso (Instituto de Diversidad y Evolución Austral, Chubut, Argentina) for comments on  
607 software implementation. We also acknowledge Nicolás Vidal and staff of the MNHN for  
608 lending material under their care, and Karla Schneider (IZH) who let us analyze specimens under  
609 her care.

# Figure 1

Fig. 1. Maximum Likelihood tree

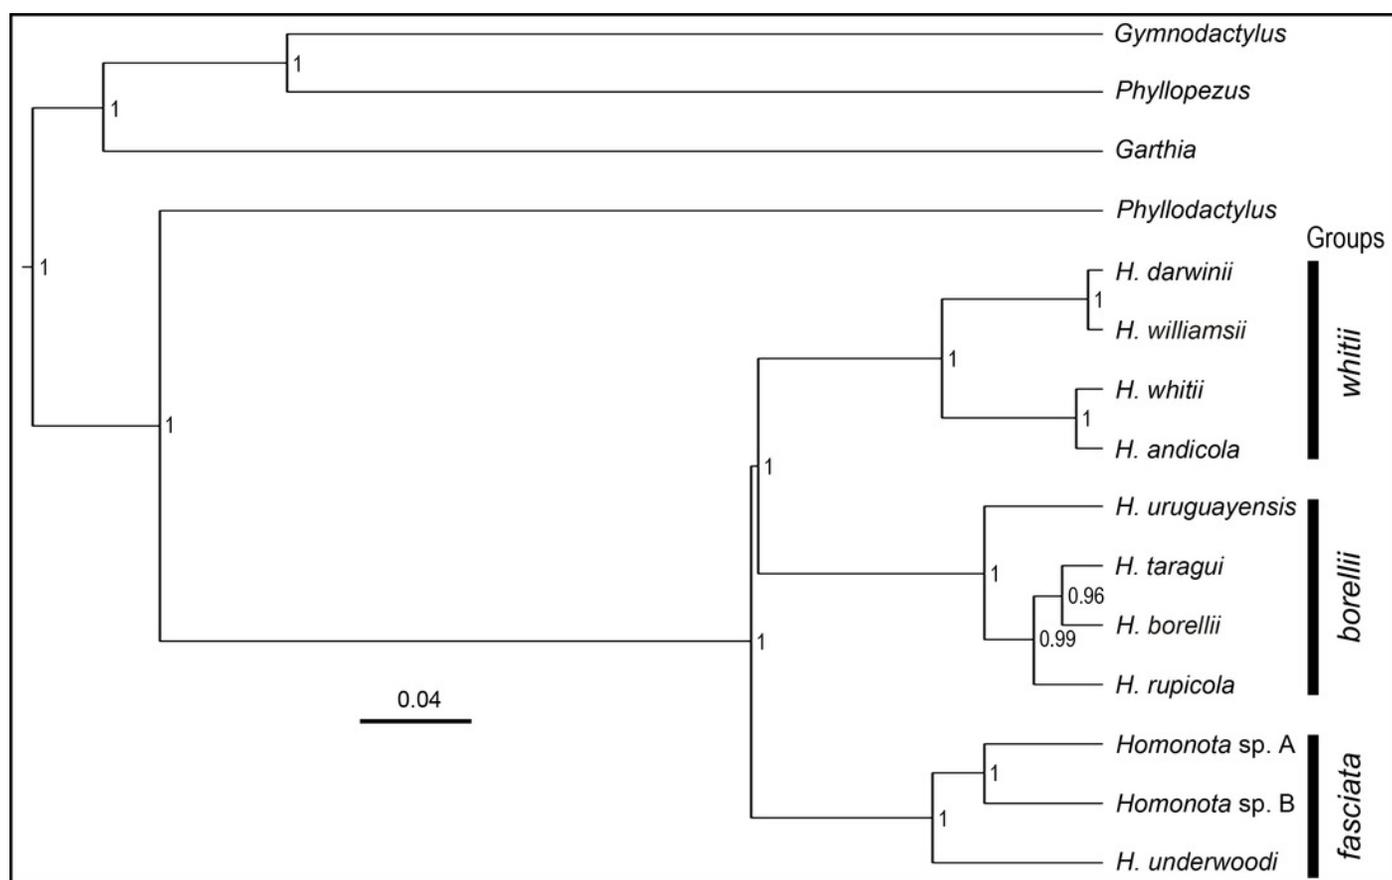

Maximum Likelihood clusters of *Homonota fasciata* from Argentina (blue polygon) and from Paraguay (red rectangle), obtained from 16S mtDNA barcode sequences. Until name assignment, we refer to them as *Homonota* sp. A and *Homonota* sp. B respectively. Outgroup: *Phyllopezus przewalskii*.

## Figure 2

Fig. 2. Species tree

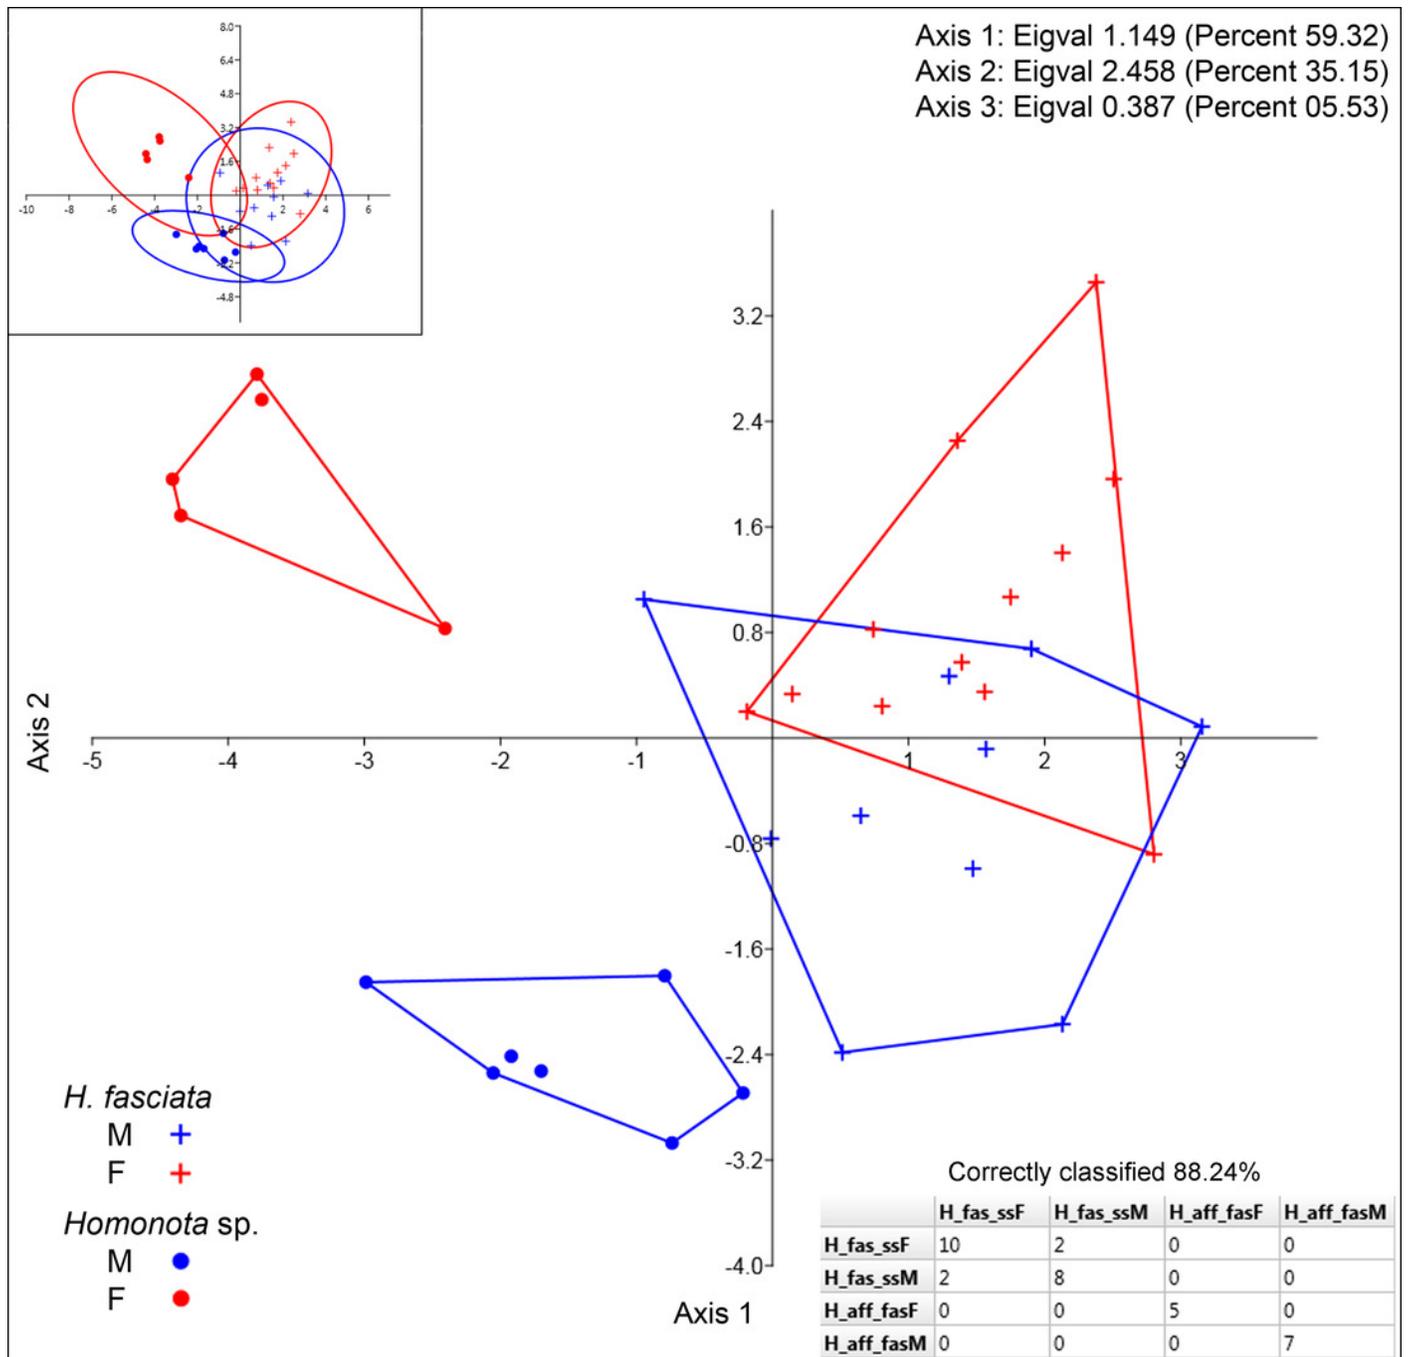

Species tree of *Homonota* and related taxa inferred with \*Beast, showing the position of the two clades (*Homonota* sp. A and *Homonota* sp. B) formerly referred as *H. fasciata*. Bar represents substitutions per site. Only values  $\geq 0.95$  are shown.

## Figure 3

Fig. 3. Discriminant analysis of continuous variables

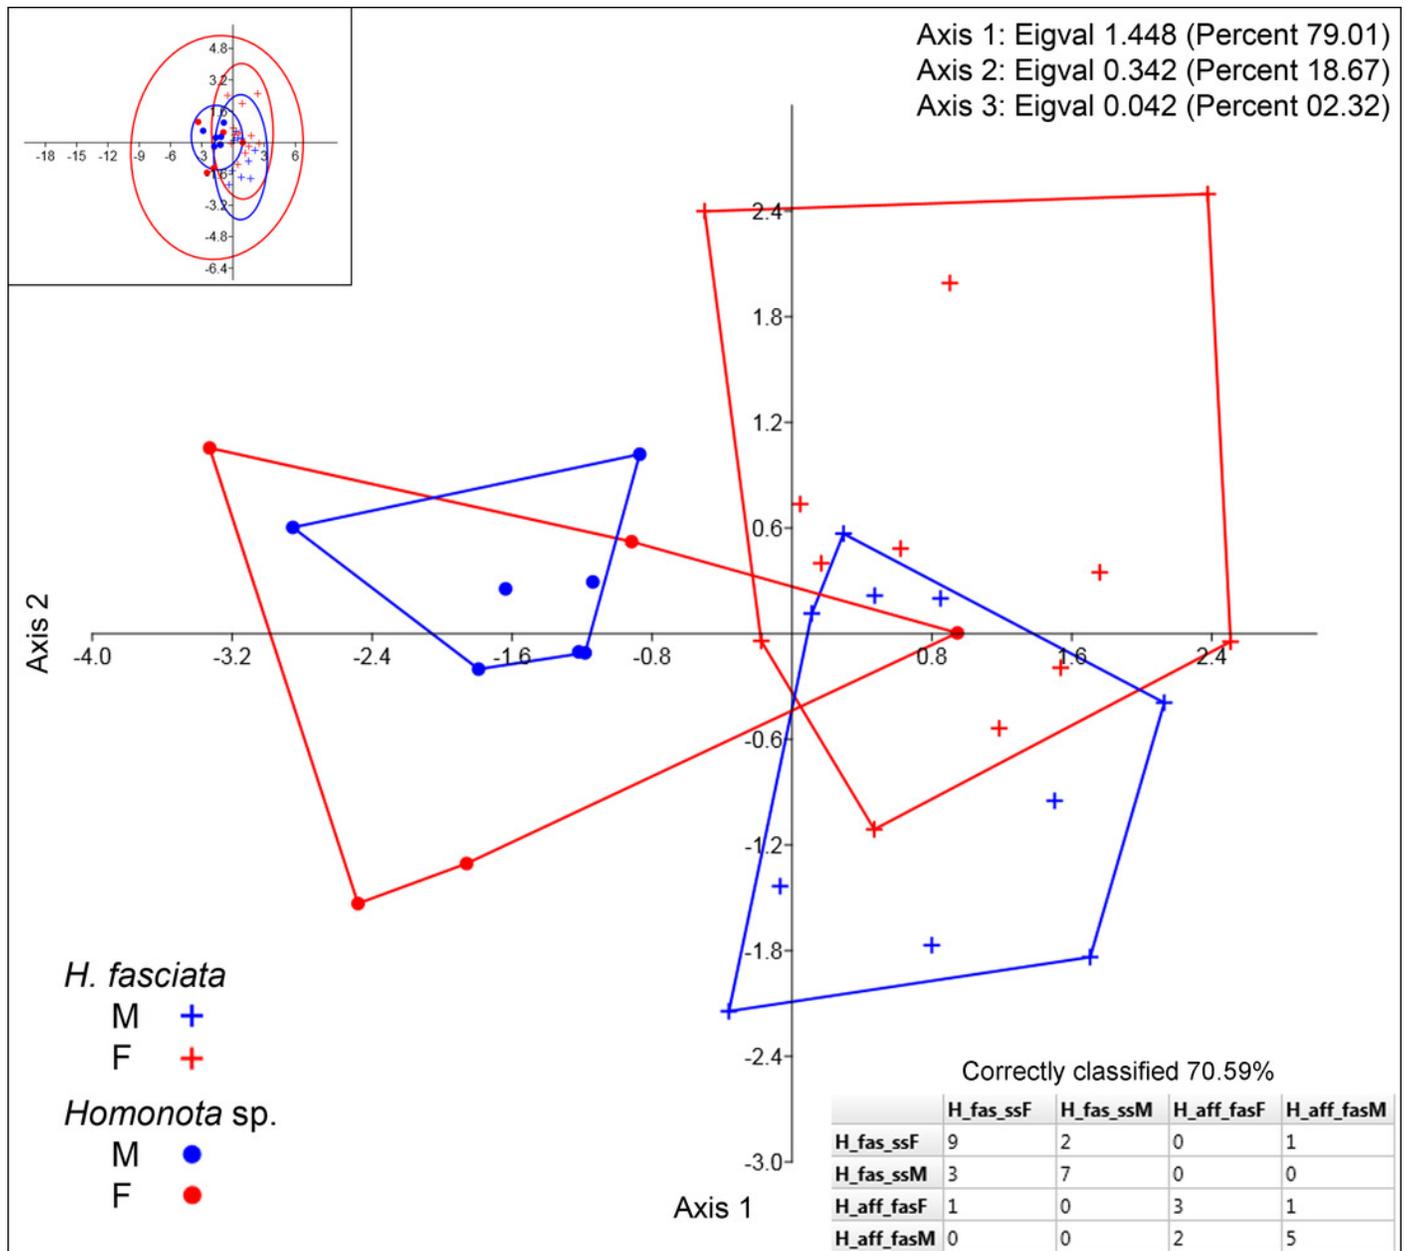

DA scatter plot of individual scores of the three most informative axes for continuous variables (See Appendix S10) of *Homonota* sp. A (Hspa in the table) and *Homonota* sp. B (Hspb in the table). Capital letters “F” and “M” refer to females and males respectively. Inset on upper left corner shows the 95% confidence intervals.

## Figure 4

Fig. 4. Discriminant analysis of discrete variables

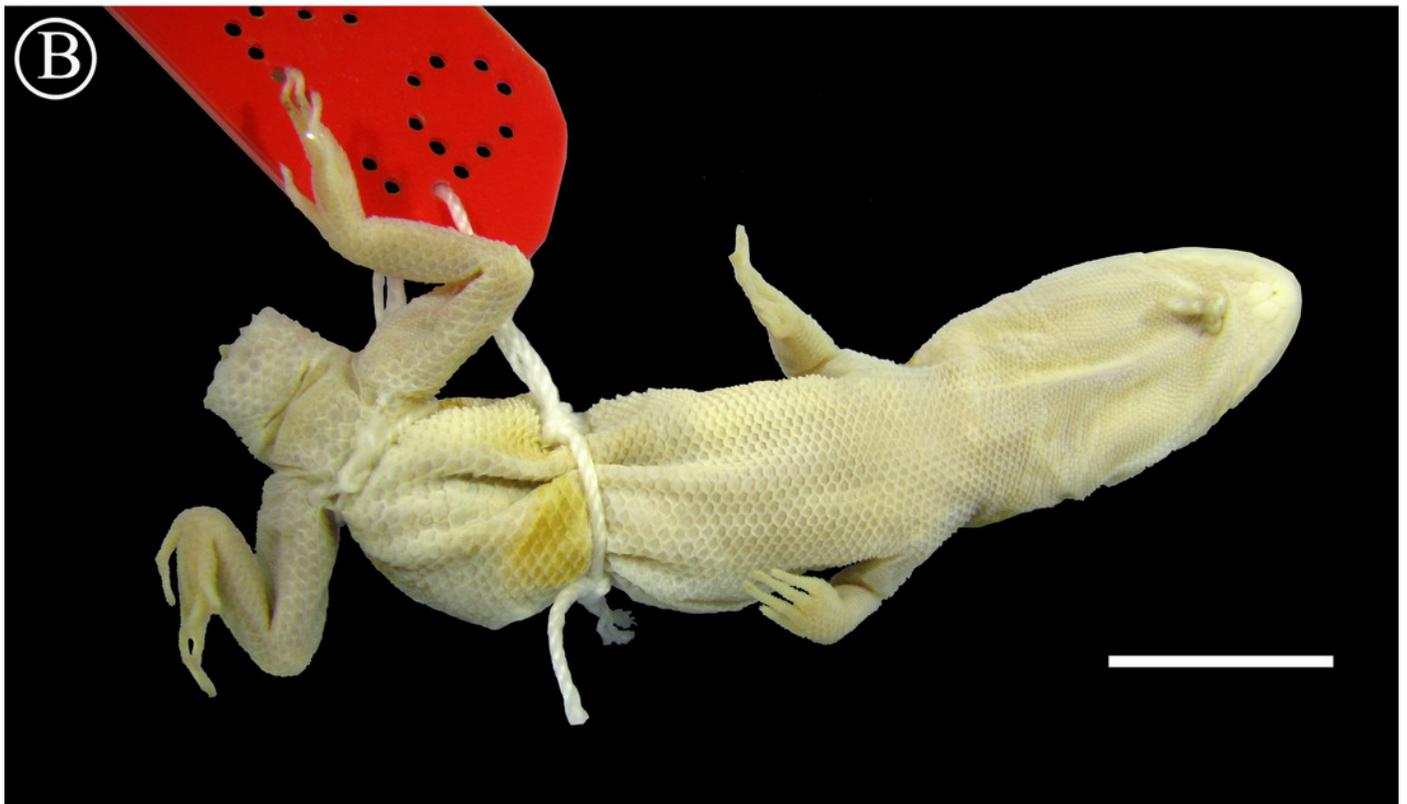

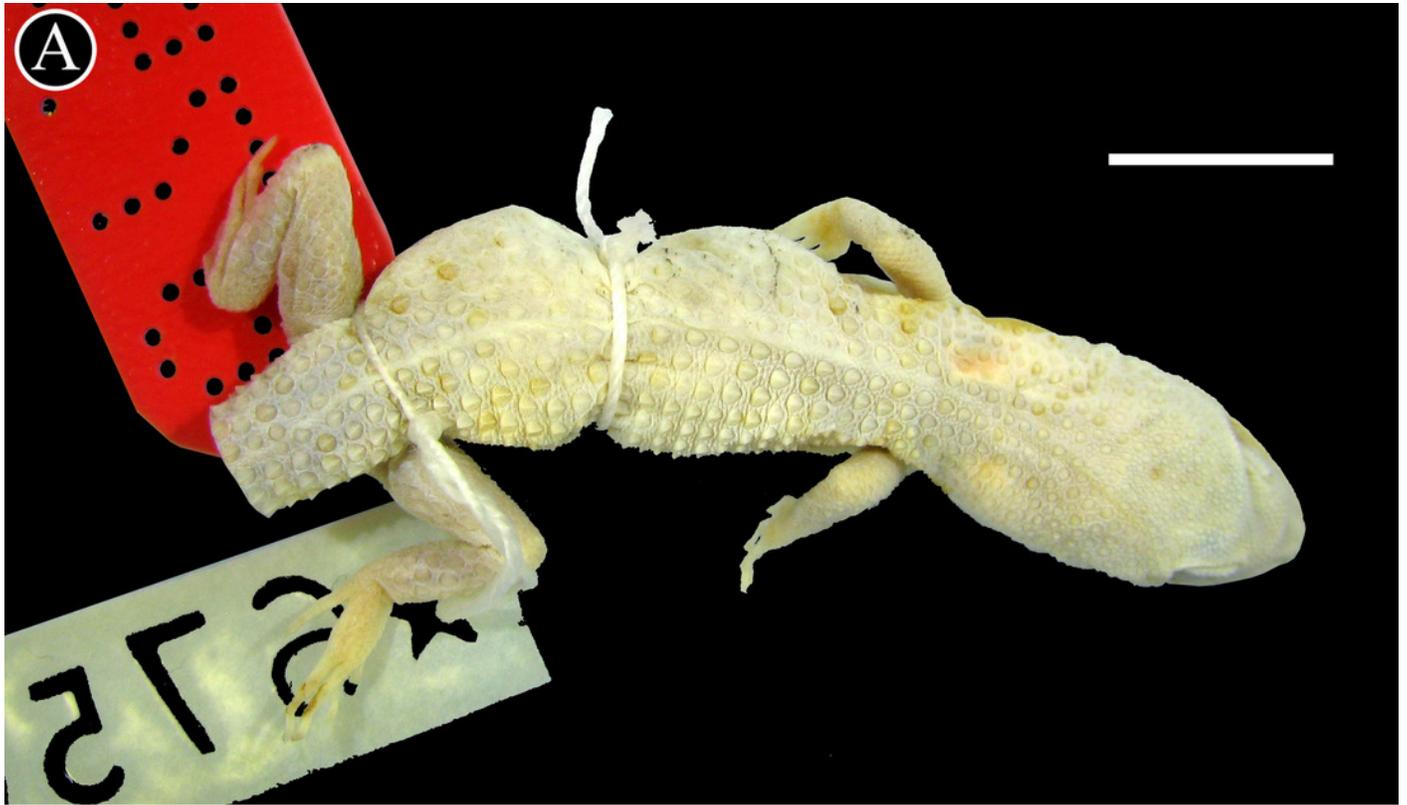

DA scatter plot of individual scores of the three most informative axes for discrete variables (See Appendix S10) of *Homonota* sp. A (Hspa in the table) and *Homonota* sp. B (Hspb in the table). Capital letters “F” and “M” refer to females and males respectively. Inset on upper left corner shows the 95% confidence intervals.

## Figure 5

Fig. 5. Image of holotype of *Homonota fasciata*

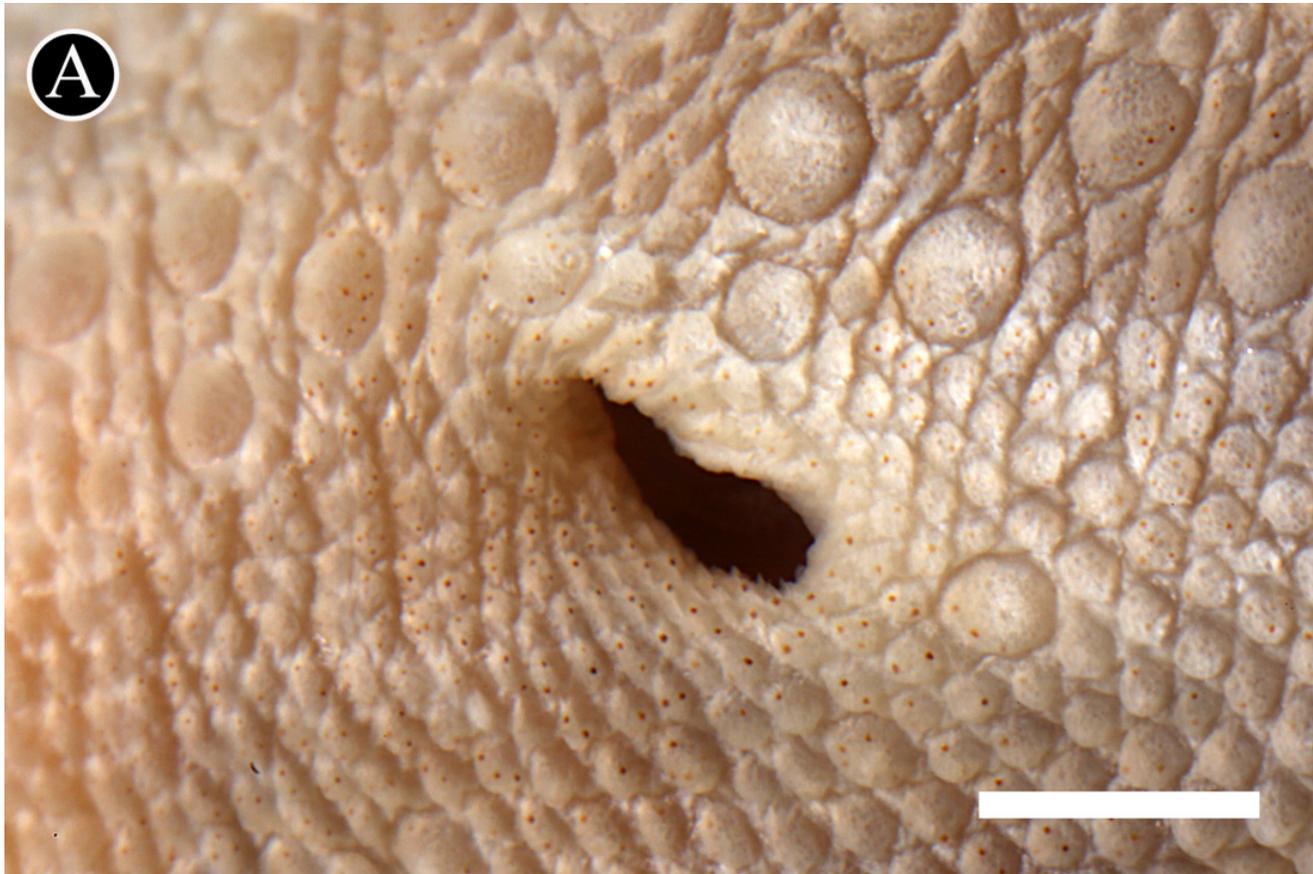

Dorsal (A) and ventral (B) views of the holotype of *Homonota fasciata* (MNHN 6756). Scale bar = 1 cm.

## Figure 6

Fig. 6. Auditory meatus

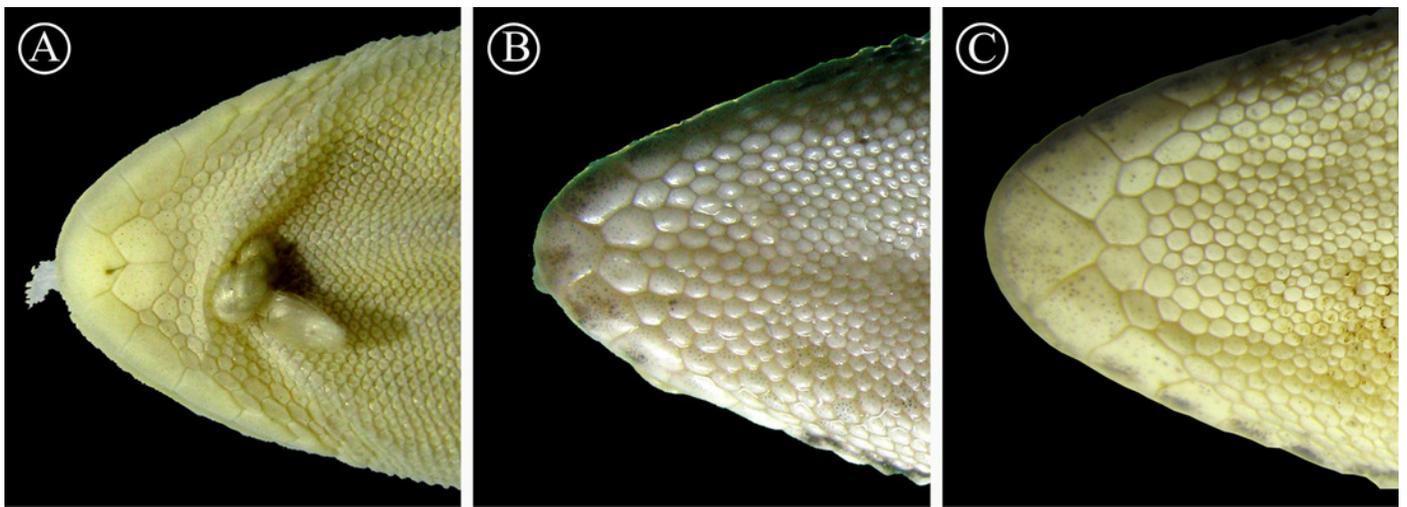

Detail of the auditory meatus of the holotype of *H. fasciata* (A) showing an even edge, and *Homonota* sp. (B) showing the serrate edge. Black arrow indicates an enlarged tubercle associated to the upper edge of the auditory meatus, absent in the holotype of *H. fasciata*. Head to the right. Scale bar = 1 mm.

## Figure 7

Detailed view of postmental scales.

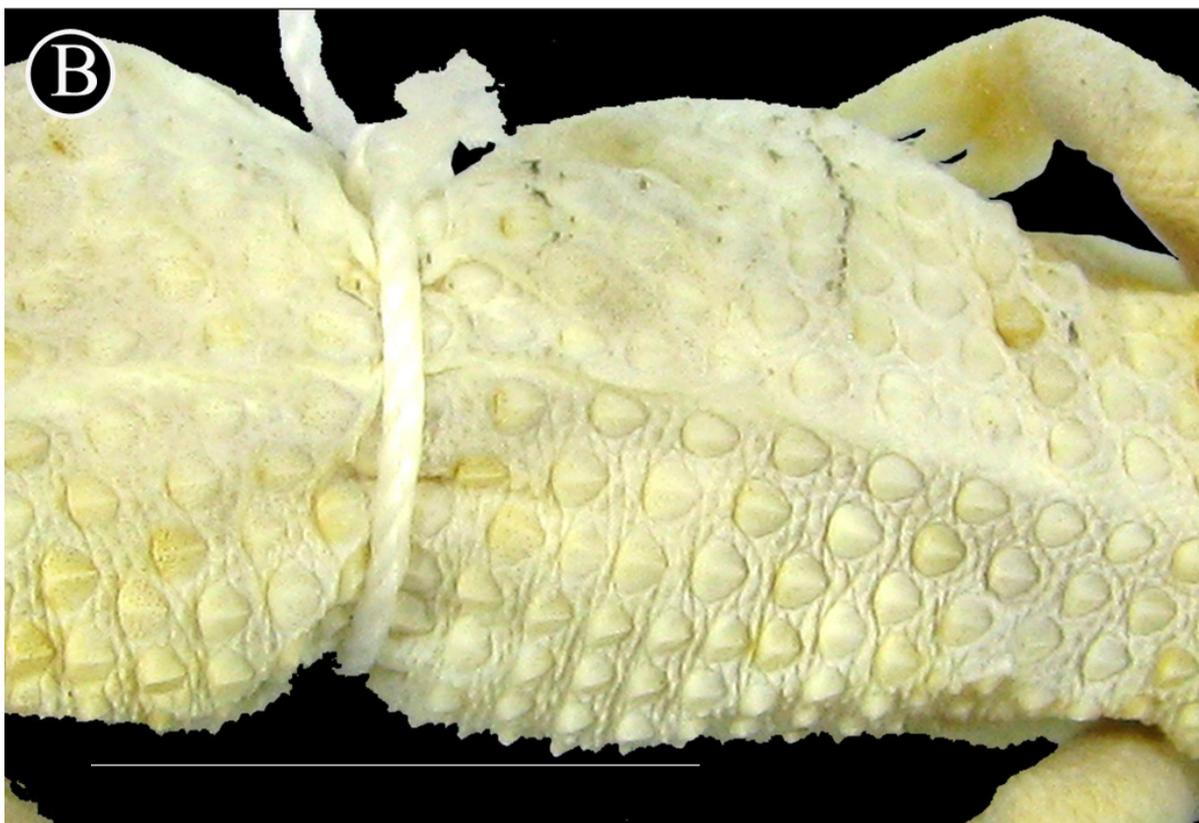

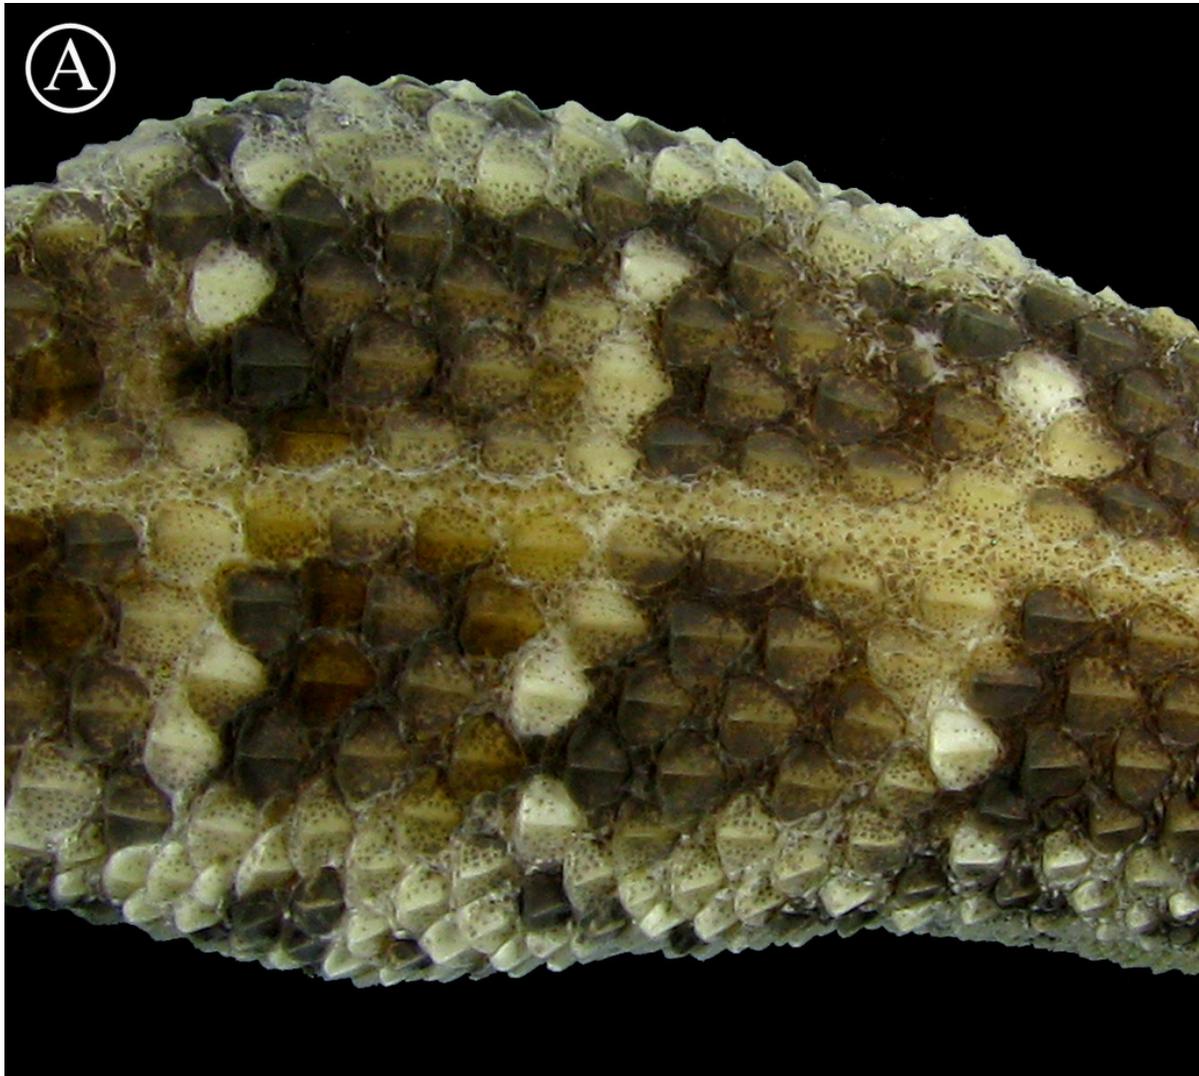

Detail of the mental region, showing the large size of the postmental scales of the holotype of *H. fasciata* (A), compared with *Homonota* sp. A (B) and *Homonota* sp. B (C). Vouchers: A- MNHN 6756; B- MNHNP 12238; C- LJAMM-CNP 6520.

## Figure 8

Detailed view of dorsal scales.

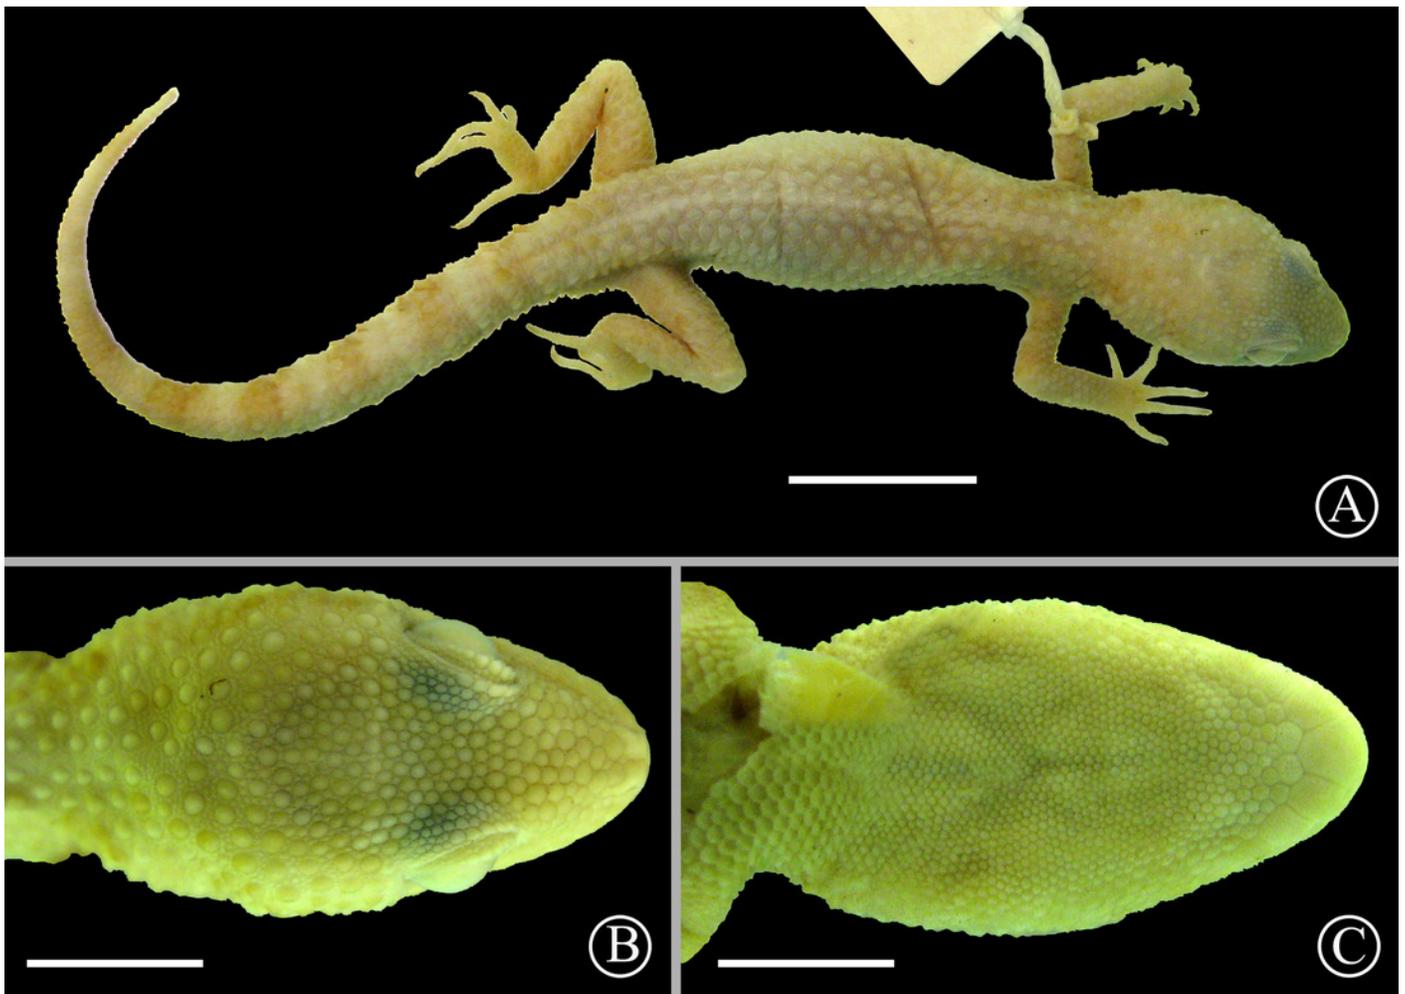

Lineal arrangement of dorsal scales of *Homonota* sp B. (A) commonly referred to as *H. fasciata*, and the holotype of *H. fasciata* (B). Note the different pattern in the squamation. Head to the right.

## Figure 9

Lectotype of *Homonota horrida* (IZH-R 1).

Dorsal view (A) and details of the head in dorsal (B) and ventral (C) views of the lectotype of *Homonota horrida* (IZH-R 1). Scale bar = 10 mm (A) and 5 mm (B-C).

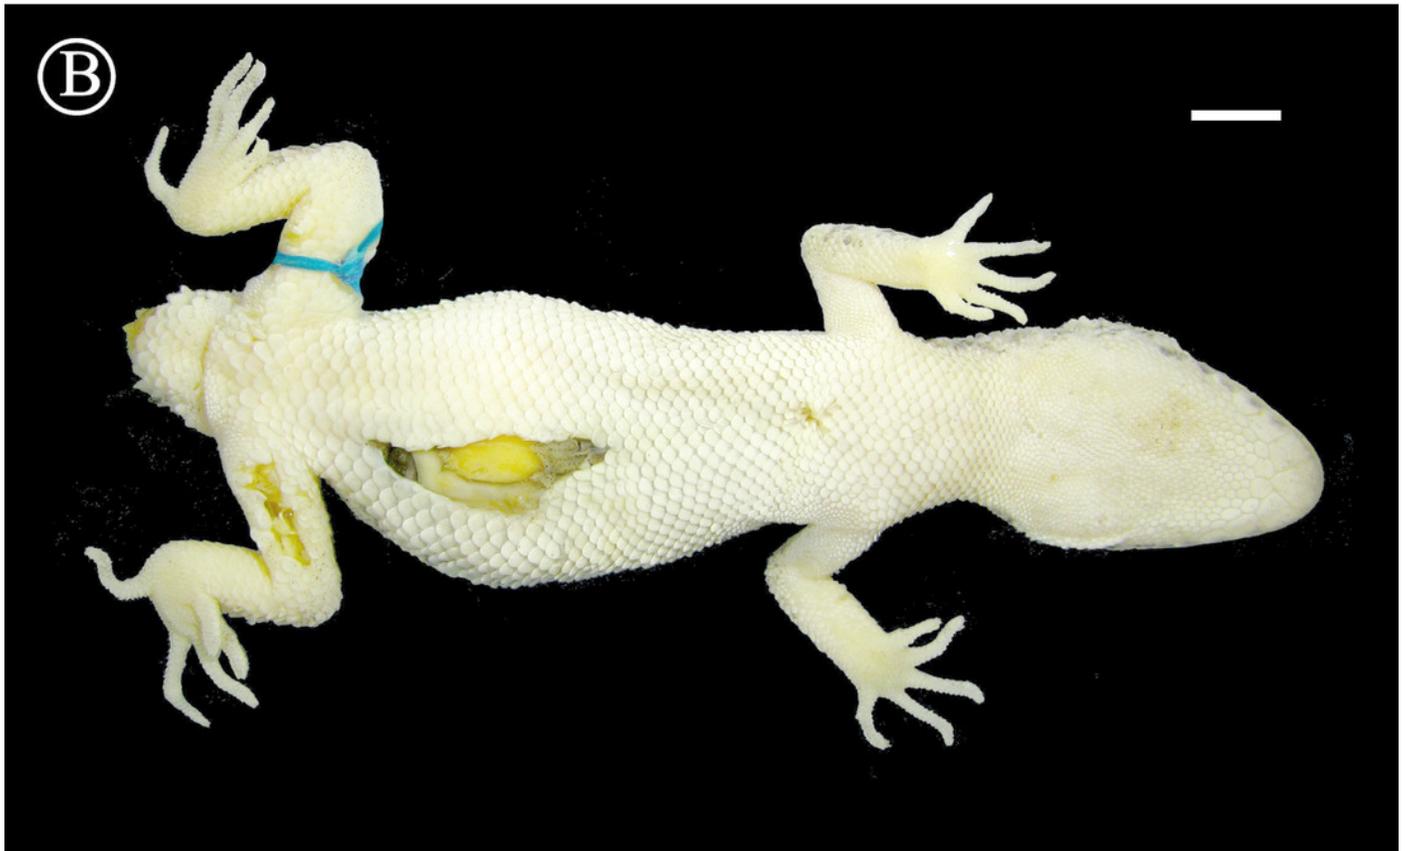

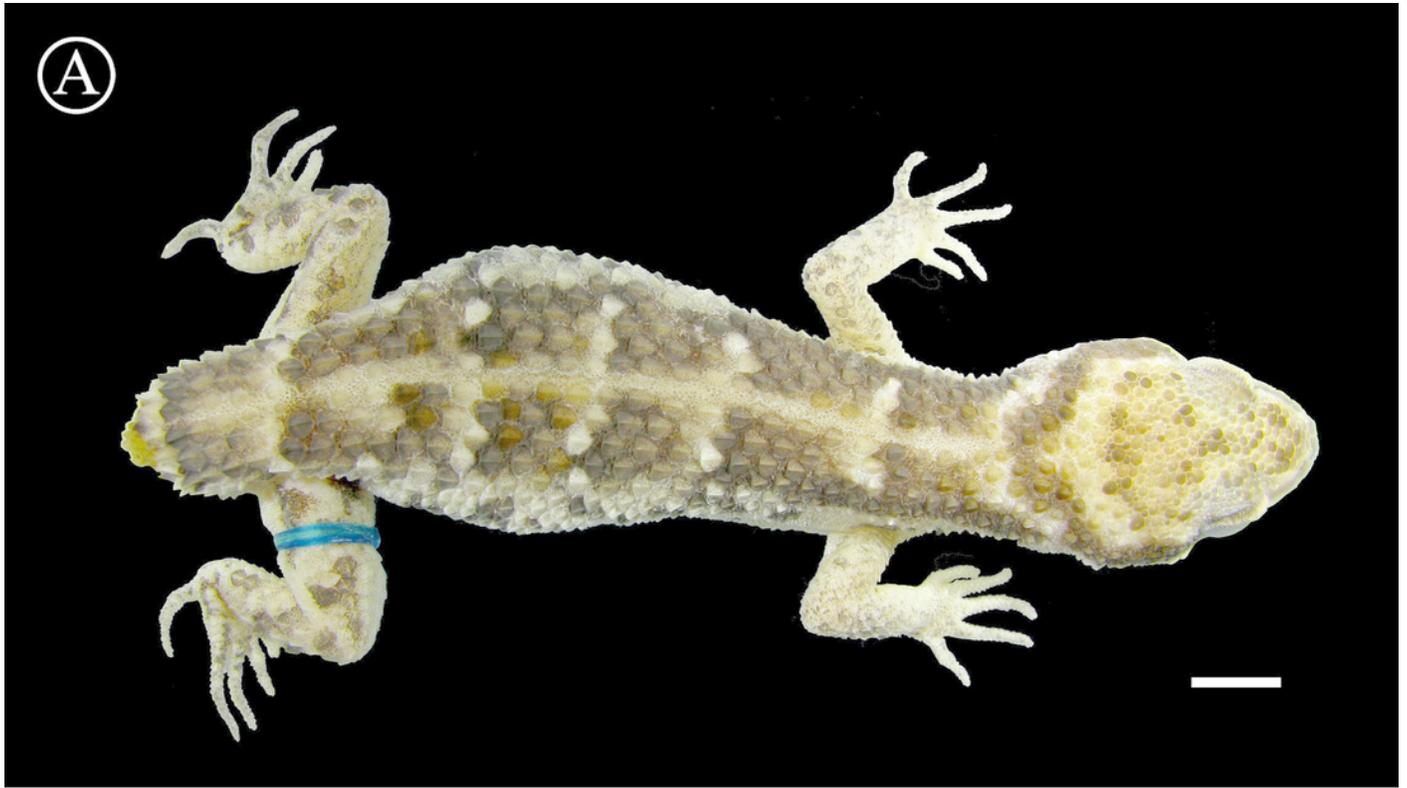

## Figure 10

Holotype of *Homonota septentrionalis* (MNHNP 12238).

Dorsal (A) and ventral (B) views of the holotype of *Homonota septentrionalis* (MNHNP 12238).

Scale bar = 5 mm.

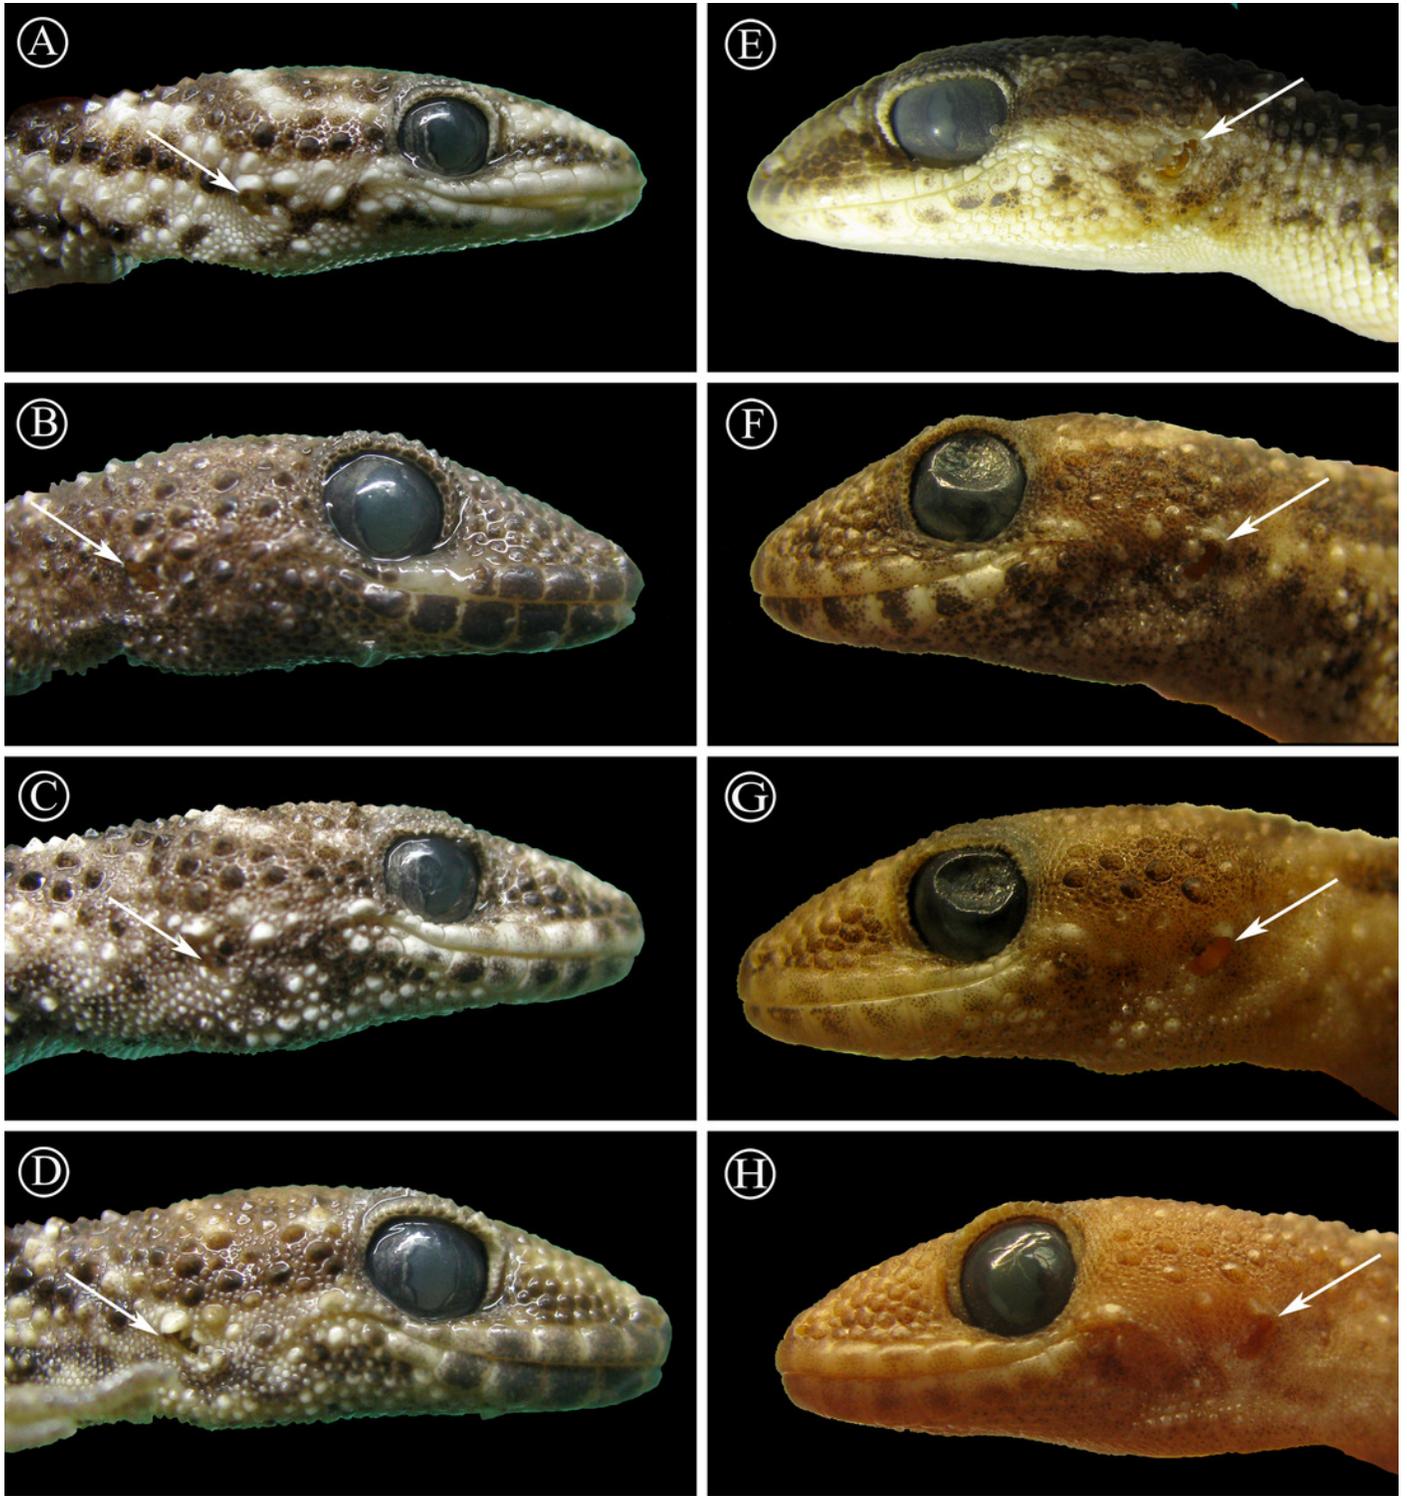

*\*Note: Auto Gamma Correction was used for the image. This only affects the reviewing manuscript. See original source image if needed for review.*

# Figure 11

## Position of ear opening

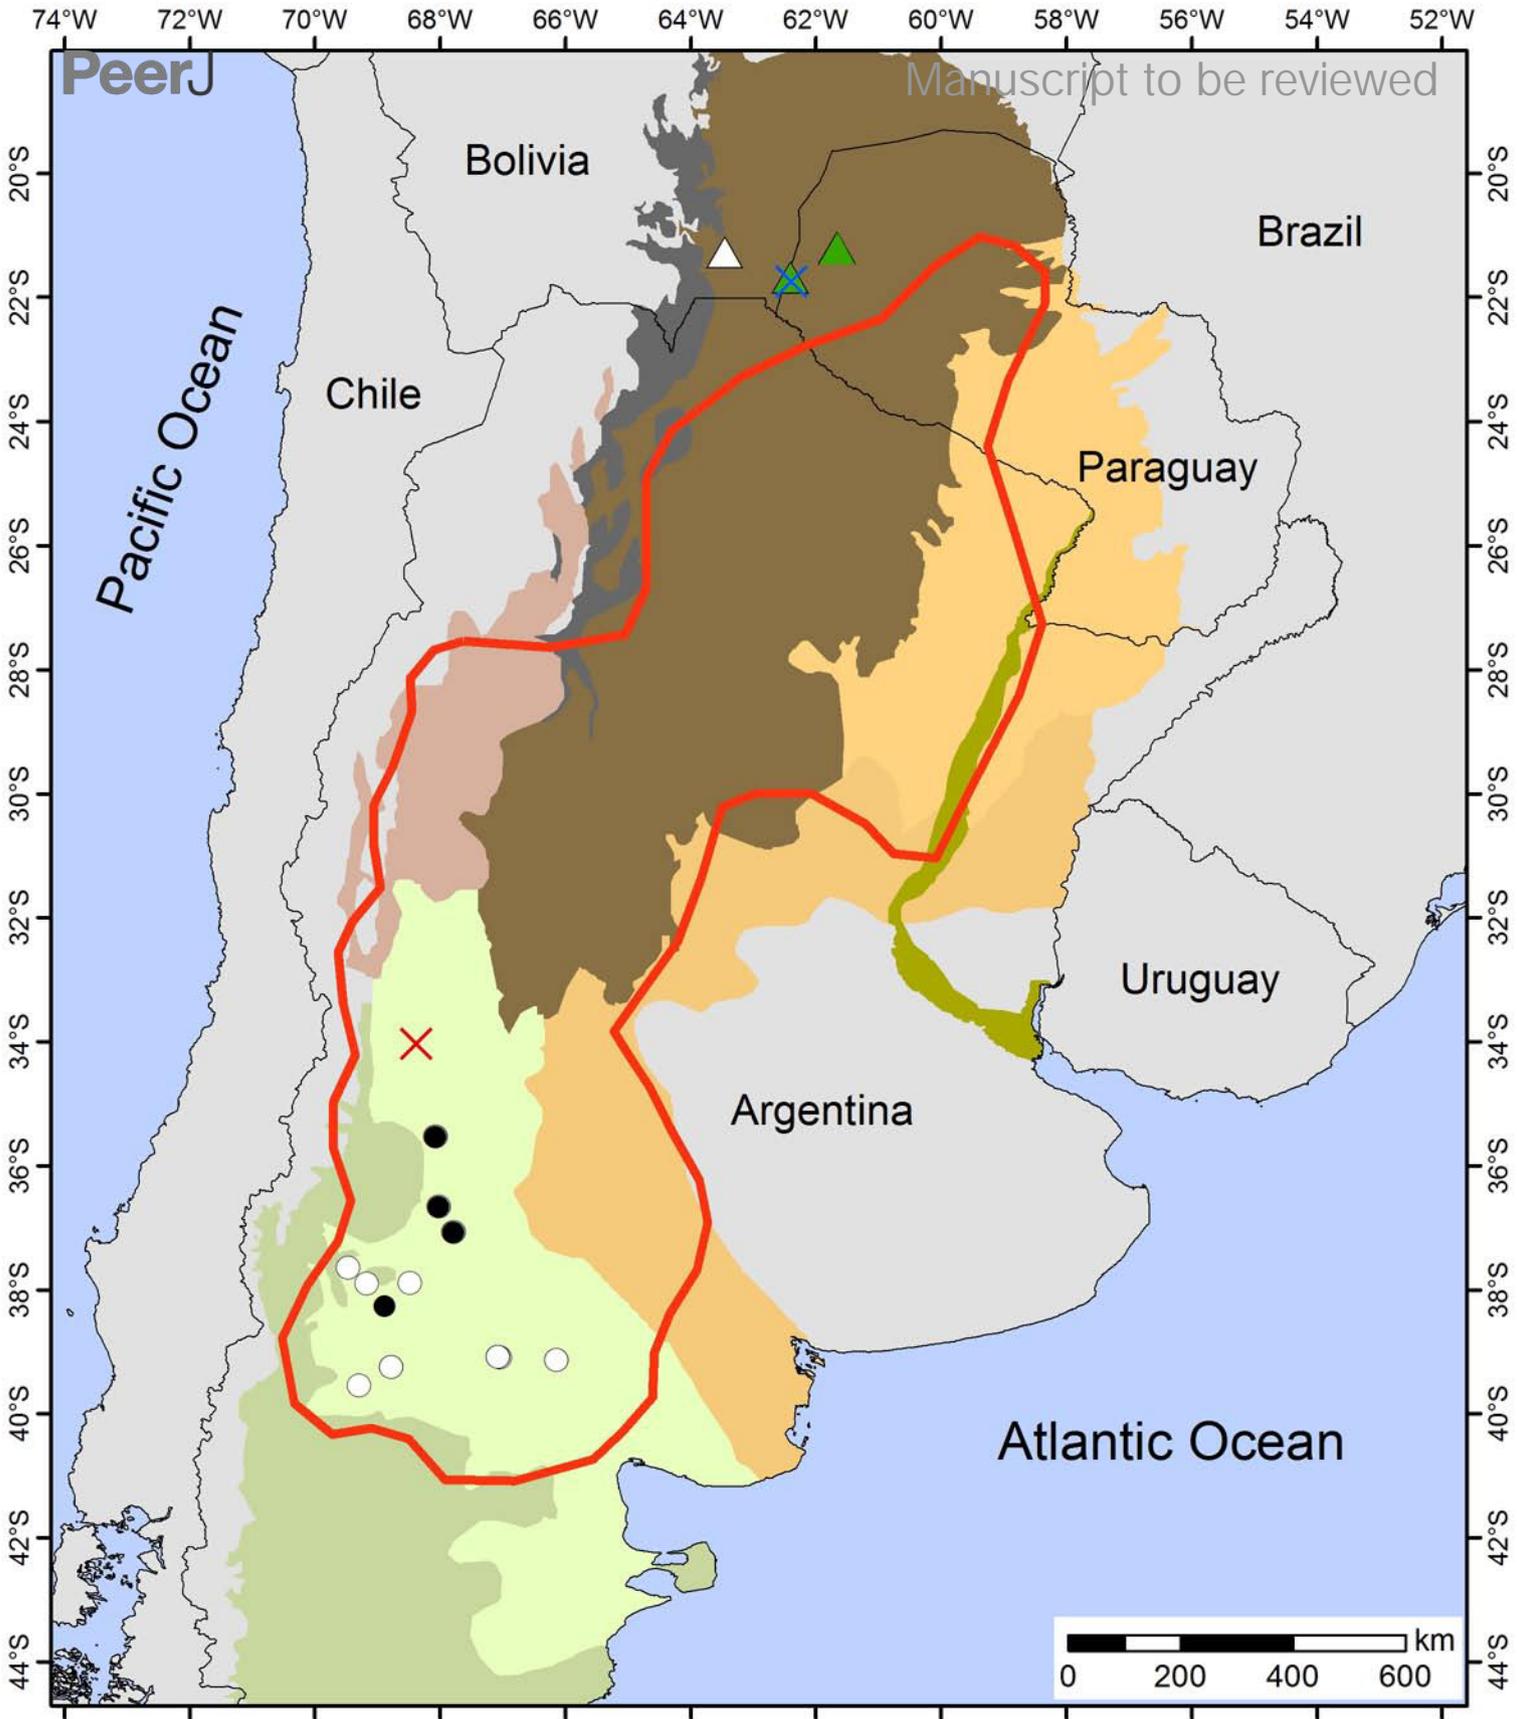

Lateral sides of the head of *Homonota horrida* (A-D) compared with *H. septentrionalis* (E-H) showing differences in the disposition of ear opening (EO), indicated with white arrows, and the tubercles between the EO and the commissure of the mouth. Vouchers: LJAMM-CNP 6520, 6532, 6533, 7670 from A to D respectively, and MNHNP 12238, MNHNP 11855, 11406, 9131 from E to H respectively.

**Figure 12**(on next page)

Fig. 12. Distribution of *Homonota septentrionalis*

Locality records of *Homonota septentrionalis* (triangles) highlighting localities of specimens used for genetic analyses (green triangles), and the distribution of *Homonota horrida* according to Morando et al. (2014) with localities of specimens used for morphological analyses (white circles) and genetic analyses (black circles). Crosses represent type localities: blue for *H. septentrionalis*, and red for *H. horrida*.

**Ecoregions**

- Dry Chaco
- Espinal
- High Monte
- Humid Chaco
- Low Monte
- Paraná Flooded Savanna
- Patagonian Steppe
- Southern Andean Yungas

- Distribution of *H. horrida*
- Country borders

## Figure 13

Fig. 13. Habitat of *Homonota septentrionalis*

Environmental characteristics of the type locality of *H. septentrionalis*.

**Table 1** (on next page)

Pairwise distances for 16S

Uncorrected pairwise genetic distances (in percentages) based on 16S mtDNA among samples of Species A from Argentina (white cells) and Species B from Paraguay (gray cells) formerly referred as *H. fasciata*. Minimum and maximum values between species in bold.

**Table 4**(on next page)

Morphological differences

Differences in morphological traits between MNHN 6756 (holotype of *Homonota fascia*) and *Homonota* sp. commonly referred as *H. fascia*.

**Table 4**

Differences in morphological traits between MNHN 6756 (holotype of *Homonota fascia*) and *Homonota* sp. commonly referred as *H. fascia*.

Trait	MNHN 6756	<i>Homonota</i> sp.
Margin of auditory meatus	Smooth	Strongly serrated
Enlarged tubercle on the auditory meatus	Absent	Present
Postmental scale	Exceptionally large	Almost same size of first infralabial
Dorsal scales	Small and widely spaced	Large and juxtaposed
