A Survey of Authors Publishing in Four Mega-Journals

Aim– To determine the characteristics of mega-journal authors, the nature of the manuscripts they are submitting to these journals, factors influencing their decision to publish in a mega-journal, sources of funding for article processing charges (APCs) or other fees and their likelihood of submitting to a mega-journal in the future. **Methods** – Web-based survey of 2,123 authors who recently published in BMJ Open, PeerJ, PLOS ONE or SAGE Open. **Results** – Response rate ranged from 26% for BMJ Open to 47% for SAGE Open. The authors were international, largely academics who had recently published in both subscription and Open Access (OA) journals. Across journals about 25% of the articles were preliminary findings and just under half were resubmissions of manuscripts rejected by other journals. Editors from other BMJ journals and perhaps to a lesser extent SAGE and PLOS journals appear to be encouraging author to submit manuscripts that were rejected by other journals to mega-journals published by the same publisher. Quality of the journal and speed of the review process were important factors across all four journals. Impact factor was important for PLOS ONE authors but less so for BMJ Open authors, which also has an impact factor. The review criteria and the fact the journal was OA were other significant factors particularly important by PeerJ authors. The reputation of the publisher was an important factor for SAGE Open and BMJ Open. About half of PLOS ONE and around a third of BMJ Open and PeerJ authors used grant funding for publishing charges while only about 10% of SAGE Open used grant funds. Around 60% of SAGE Open and 32% of PeerJ authors self-funded their publication fees however the fees are modest for these journals. The majority of authors from all 4 journals were pleased with their experience and indicated they were likely to submit to the same or similar journal in the future. **Conclusions** - Mega-journals are drawing an international group of authors who tend to be experienced academics. They are choosing to publish in mega-journals for a variety of reasons but most seem to value the quality of the journal and the speed of the review/publication process. Having a broad scope was not a key factor for most authors though being OA was important

for PeerJ and SAGE Open authors. Most authors appeared pleased with the experience and indicated they are likely to submit future manuscripts to the same or similar mega-journal which seems to suggest these journals will continue to grow in popularity.

9   **Introduction**

10 With the launch of PLOS ONE in 2007 and its phenomenal growth over the last 7 years, megajournals
11 have become a major venue for disseminating scientific research. These journals are open access (OA),
12 have broad scopes; a review process focusing exclusively on whether the methodology is sound and an
13 accelerated publication process. There are now over 20 such journals including recently announced
14 megajournals from the Royal Society, the American Association for the Advancement of Science and the
15 American Educational Research Association. While the growth of PLOS ONE has moderated, the growth
16 of megajournal publishing as a whole continues to be exponential and in total these journals are now
17 publishing approximately 4,000 articles a month (Binfield, 2013) or an estimated 2.5% of the total
18 scholarly articles published based on estimates from Ware & Mabe, (2012) Clearly many authors are
19 finding this form of publication attractive.

20 Although author surveys have been conducted by megajournal publishers (Patterson M, 2011; PeerJ,
21 2013), to my knowledge there has not been an independent survey of megajournal authors. As one might
22 expect, publisher surveys have focused on the author experience with the submission, review and
23 publication processes. While these issues are important, the factors that influence authors to choose to
24 publish in a megajournal and the means by which they are able to fund the article processing charge
25 (APC) or other fees are also important issues in understanding this new form of scientific publishing.

26 The Scientific, Technical and Medical (STM) publishing market alone is approaching 10 billion USD with
27 about 73% of the 11,550 English language journals from non-profit publishers (Ware & Mabe, 2012). If
28 authors find this new form of publishing attractive and begin publishing a significant portion of their
29 manuscripts in in megajournals, this could have a profound impact on scientific publishing for both
30 societies and commercial publishers. The increasing number of major societies such as AAAS and AERA
31 launching these journals highlights this potential shift in scholarly publishing.

32 .The growth of the APC funded OA market itself is becoming disruptive to the publishing industry. The
33 shift from funding publication via subscriptions to an APC funded model used by the majority of
34 megajournals shifts from readers or their proxy being the purchaser of publishing services to authors,
35 their institutions and/or their funders being the purchaser. The factors that influence authors' choice of a
36 journal and the sources of funding they have available for paying publishing charges becomes much more
37 critical when publishing is funded through publishing fees. How authors feel about this issue has broad
38 implications for maintaining a transparent, cost effective and competitive market for APC funded
39 publication. (Björk and Solomon, 2014). Understanding how authors are funding fees and how these fees
40 are impacting on their choice of where to publish their research is essential for understanding the
41 economics of this funding model and the extent we are likely to see a transparent and reasonably priced
42 scholarly publishing system if megajournals continue to gain an increasing share of the scholarly
43 publishing market.

44 I conducted a web-based survey of corresponding authors who recently published articles in four
45 megajournals. These included PLOS ONE, BMC One, SAGE Open and PeerJ. I chose PLOS ONE and

46 BMJ Open because they were established biomedical journals in operation long enough to receive an
47 impact factor. SAGE Open is the only established megajournal in the social sciences and offered
48 interesting cross discipline comparison with the mostly biomedical journals that were launched after the
49 success of PLOS ONE. PeerJ is a very innovative biomedical megajournal with a unique membership
50 funding model and also offered an interesting comparison with the other three journals. Table 1 provides
51 basic information on each journal. While there were about 20 megajournals in operation at the time this
52 study was completed, I had limited resources and felt these four journals offered a representative picture
53 of the authors publishing in this journal format.

54 The goals of the survey were describing the authors choosing to publish in these four megajournals;
55 determining the factors influencing their decision to publish in the journal they chose and the means by
56 which they funded the APC or in the case of PeerJ, the membership fee. I was also interested in whether
57 their article was a resubmission after being rejected by another journal and whether these articles
58 described preliminary research that and was the basis of what the authors planned to publish in more
59 complete form in another venue, in other words were these journals containing largely preliminary work
60 or manuscripts authors had difficulty publishing elsewhere. Authors were also asked the likelihood of
61 submitting a manuscript to that journal or another similar megajournal. I would have like to ask a broader
62 set of questions but felt it was important to keep the survey short in the interest of increasing response
63 rates from the busy researchers publishing in these journals. As noted this new form of scientific
64 publishing has grown quickly and new megajournals are rapidly being launched. Understanding the type
65 of material that is being published, the motivations for authors choosing to publish in these journals and
66 how they are funding author fees is essential for understanding the rapidly evolving scholarly publishing
67 system. This information is useful for funding agencies, scholarly socieities and libraries in adjusting to
68 the rapidly evolving scholarly publishing ecosystem.

69 **Methodology**

70 **Sample** - I sampled authors who published in BMJ Open and SAGE Open during 2013. The journals had
71 published around 800 and 300 articles respectively during 2013. Using software I developed, I "scraped"
72 the corresponding author's name, email and the title of the article off the publisher's web site. The
73 software was run in mid-December 2013 and I attempted to scrape all the published articles starting in
74 January 2013 up until the time the data were collected.   PLOS ONE published over 30,000 articles during
75 2013, far more than would be reasonable to sample. I originally sampled about 1,000 authors whose
76 articles were published during the first 2 weeks of December2013 scraping the author contact information
77 from the PLOS ONE web site using similar software as used for BMC Open and SAGE Open.   These
78 were used to pilot the survey, software and email contact procedures. Due to changes in the survey based
79 on the pilot results and an error in the software that failed to record one of the questions; these data were
80 not used in the study. I sampled approximately 1,000 PLOS ONE authors whose articles were published
81 in the last two weeks of January 2014. PeerJ provided me with equivalent author information for all the
82 authors publishing in PeerJ from its launch in February 2013 through February 2014.

83 The email lists were stripped of duplicates and a few of the data records had names and other information
84 garbled by inconsistencies in the character set during the scraping process. Where it was not possible to
85 reconstruct the information, these authors were not used in the study. A total of 935, 728, 231 and 234
86 authors were surveyed from PLOS ONE, BMJ Open, SAGE Open and PeerJ respectively resulting in a
87 grand total of 2,128 authors surveyed.

88 **Survey** - I followed guidelines outlined by Dillman (2000) in an attempt to maximize survey response
89 rates. Email requests to participate in the survey were addressed to authors by name with the title of their
90 recently published article. A survey link was provided for completing the survey including a a coded ID
91 passed via the URL that identitied the author. While the survey data remained anonymous, authors
92 completing the survey were flagged in the data table with their emails indicating they had completed the

93 survey. Authors who did not complete the survey were sent a reminder email approximately one week
94 after the original email. An example of the survey can be viewed at:

95 http://openaccesspublishing.org/survey/Example_Survey.html

96 A slightly different version of the survey was used for the authors publishing in PeerJ to reflect the
97 membership funding model as opposed to the APC funding model used by the other 3 journals. An
98 example of the PeerJ survey can be viewed at:

99 http://openaccesspublishing.org/survey/Example_PJsurvey.html

100 Where appropriate, chi-square tests were performed to assess the probability the differences in the
101 percentages in the authors' responses among the journals were do to chance. Where where the probability
102 the differences were greater than $p < 0.01$ it is noted in the tables legends.

103 The survey protocol was deemed exempt by the Michigan State University Biomedical and Health
104 Institutional Review Board, IRB Number: x14-029e; i045267.

105 **Results**

106 Authors were given the opportunity to include written comments concerning their employment, choice of
107 a journal and more general comments about their experience publishing in the megajournal they chose.
108 The comments in a PDF format and a copy of the data in Excel format are available at:

109 http://dx.doi.org/10.6084/m9.figshare.962954

110 The software used to scrape the author names and email addresses and the email sent to the authors
111 requesting their permission are also included at the URL above.

112 About 35 of the authors'emails were not valid. SAGE Open had the highest response rate at around
113 47%, followed by PeerJ at around 40% with substantially lower response rates for PLOS ONE and BMJ
114 Open at 29% and 26%. A total of 665 authors responded to the survey. These results are roughly
115 consistent with a similar survey I conducted with a colleague that included OA journals charging APCs
116 from a wide range of disciplines. (Solomon & Björk, 2012).

117 Approximately 25% of the authors across all the journals and 40% of the authors of PeerJ and SAGE
118 Open articles were from the USA.   United Kingdom and Australia published the highest percentage of
119 articles in BMJ Open. Articles were most evenly distributed geographically in PLOS ONE but all four
120 megajournals were very international with authors spanning the globe. A listing of the number of articles
121 from each country for each of the four journals is contained in the supplemental materials.

122 Table 2 describes the positions held by the corresponding authors. A further description of the tenure status
123 and rank of authors with academic positions is contained in the supplemental material. It should be noted
124 that in many countries the concept of tenure and the way faulty ranking is none did not conform to the
125 way it is categorized in the survey. The authors were allowed to mark multiple types of positions and so
126 the percentages of authors marking each category add up to more than 100% and the counts add up to
127 more than the total number of authors.   Most of the authors, about 85% publishing in each journal are
128 academics. Over a fifth of the PLOS ONE authors worked in research laboratories as did 16% of the
129 PeerJ authors. Much lower percentages of BMC Open and SAGE Open authors worked in laboratories.
130 Roughly 10% of the authors worked for the government with the percentage being a little higher for BMJ
131 Open. Only a very small percentage of the authors worked in private industry.

132 Authors were asked about their previous publishing history both in terms of subscription and open access
133 journals. Table 3a and 3b present these results. Most of the authors had at least some experience over the
134 last few years publishing in both subscription and open access journals with PeerJ authors appearing to
135 having slightly more experience publishing in OA journals as compared with the other authors.

136 Authors were also asked whether their manuscript described preliminary findings from a study from
137 which they planned to publish more complete data at a later date and whether the paper was a
138 resubmission of a manuscript they had attempted to publish in another journal. Table 4a and 4b present
139 the results. About 10% of the manuscripts in PeerJ were described by their authors as preliminary
140 findings while the percentage was more than double that in the other three journals. Two thirds of the
141 articles in BMJ Open were resubmissions; slightly fewer than half the articles in PLOS ONE and SAGE
142 Open and about 37% in PeerJ were resubmissions.   Comments from authors publishing in BMJ Open,
143 PLOS ONE and SAGE Open indicated that in at least some of the cases, journal editors from the same
144 publisher (BMJ, PLOS and SAGE) encouraged the authors to submit their manuscript to the publisher's
145 megajournal after it was rejected in the original journal. These were most prevalent for BMJ where 11 of
146 the authors indicated they were encouraged by the editor of another BMJ group journal to resubmit to
147 BMJ Open. It should be noted that authors submitting to other BMJ journals can ask that their manuscripts
148 be automatically considered by BMJ Open if not accepted by the other journal (BMJ, 2014). PLOS
149 ONE's instructions for authors indicates the publisher will help in transferring manuscripts from one
150 PLOS journal to another but seem instead encourage authors to carefully consider which PLOS journal
151 would be most appropriate for their manuscript before submission.

152 Authors were asked to rate the importance of each of 10 factors in their decision to submit their paper to
153 the megajournal in which they published. They also were asked to select the most important factor and
154 were given the option of describing other factors in a textbox. As noted above, a slightly different survey
155 was sent to PeerJ authors given the difference in funding model and that the journal has not yet been given
156 an impact factor. Two of the 10 factors listed for this question differed. Instead of impact factor authors
157 were asked to rate the importance of the website, which is fairly innovative and instead of the amount of
158 the APC they were asked to rate the importance of PeerJ's membership funding model. Importance was
159 rated on a four point scale from not important to very important. Authors were also given the option of
160 marking that the factor negatively influenced their decision to submit. Table 5 presents the authors'
161 selection of the most important factor and ratings of each factor and the average ratings on the four-point,
162 and the number of authors indicating the factor negatively influenced their choice of the journal. Many
163 authors failed to mark what they felt to be the most important factor but did rate the importance of the 10
164 factors.

165 The quality of the journals was a major consideration with over 20% of the authors that published in each
166 journal rating it the most important consideration. The fact the journal was open access was the major
167 consideration for PeerJ and SAGE Open authors but less of a consideration for PLOS ONE and BMJ
168 Open authors. Just over 20% of the PLOS ONE authors rated the impact factor their most important
169 consideration.

170 The authors were asked to list their sources of support for covering the APC or the membership fee in the
171 case of PeerJ. They were given the option of listing multiple sources. The results are presented in Table
172 6. The individual percentages and counts add up to more than the totals reflecting that some authors listed
173 multiple sources of funding. Two of the questions were altered for the PeerJ survey. "Institution funding
174 based on an institutional policy that funds open access publishing fees" was replaced with "Institution
175 membership." "The fee was waived" was replaced with "promotional fee waiver".

176 Approximately half the authors publishing in PLOS ONE were able to use grant funding while roughly
177 35% and 30% of PeerJ and BMJ Open respectively used grant funding. Only 11% of SAGE Open authors
178 used grant funding for the APC which is likely a reflection of the scope of the journal. The journals varied
179 considerably in terms of the percentage of authors who self-funded the cost of publication. Almost 63%

180 of SAGE Open authors using personal funds to pay the APC. It should be noted that SAGE Open reduced
181 their APC to 99 USD in January 2013 (SAGE, 2013). Approximately one third of the PeerJ's authors
182 indicated they used personal funds. Again, the membership fee for PeerJ is quite modest. Only about 11%
183 and 8% of BMJ Open and PLOS ONE authors use personal funds.

184 The authors were asked to rate on a five point scale how likely they would be to submit manuscripts to the
185 same or similar megajournal in the future. Table 7 contains the breakdown by journal. The majority of
186 authors across all journals indicated they would be likely to submit to the journal they published or a
187 similar megajournal in the future. Authors from PeerJ were most likely to resubmit with 72% indicating a
188 5 on the 5 point scale and another 20% a 4. SAGE Open authors were the least likely to submit again to
189 the same or similar journal and yet almost 50% marked a 5 and another 27% a 4. It appears that at least
190 the authors who completed the survey were satisfied enough with the experience of publishing in a
191 megajournal to seriously consider submitting to a megajournal in the future.

192 The authors were given the option to write in general comments concerning their experience with the
193 following prompt. "***Do you have any other thoughts about publishing your paper in [journal] ?***   The
194 comments, organized by journal are available in the survey data archive at the URL above.

195 Comments that were clearly not informative, such as "thanks" or "no" were removed and a blank line was
196 placed between each authors' comment. Otherwise the comments appear as received.

197 The comments across the four journals were in general quite positive reflecting the authors' indications
198 they would likely publish in the journal they had or a similar megajournal. The comments for BMJ Open
199 and in particular PeerJ were extremely positive.

200 Eleven SAGE Open and 8 PLOS ONE authors complained about the length of the review process. In
201 some cases based on the author's comments the journals had difficulty finding reviewers and/or academic
202 editors with the appropriate expertise to review the submission. Several SAGE Open authors indicated
203 they had review times of over a year. There were no such comments for BMJ Open and PeerJ. It should
204 also be noted several authors were complementary of the SAGE Open and PLOS ONE review process.
205 The APC was referenced in 18 of the comments from BMJ Open expressing a range of views.

206 **Discussion**

207 Both the number of megajournals and the articles they publish are growing rapidly. As this new format of
208 scholarly publishing becomes established there is a need to gain a better understanding of the authors who
209 are publishing in these journals, what is motivating them to choose this format and how are they covering
210 the costs of publication. I believe this is the first systematic study exploring these issues.

211 This study has limitations that should be taken into account in interpreting the results. Chief among these
212 is the potential of response bias. It is not clear how representative the respondents to the survey were of
213 all authors publishing in these journals. Since the survey was designed to keep the responses anonymous,
214 it is not possible to tell if the respondents differ in any systematic way from those who chose not to
215 respond. In an attempt to increase the response rate, the survey was kept very short and hence the
216 information that was captured is also fairly limited. In addition, scholarly articles, particularly in
217 biomedicine tend to have several authors and it is not clear the views of the corresponding authors are
218 representative of their coauthors. Only 4 journals were included in the study and may not represent
219 megajournals in general. Also author opinions may evolve over time as this form of publishing become
220 more established. Despite these and potentially other limitations the survey provides interesting
221 information about authors' thoughts and experiences publishing in these four megajournals.

222   The journals appear to be attracting a very diverse group of researchers. Despite the fact BMJ Open and
223   PLOS ONE have significant APCs, all four journals attract a very international set of authors. As one
224   might expect the authors tend to be mainly academics. The authors as a whole appeared to be fairly
225   experienced researchers who had a significant number of recent publications in both subscription and OA
226   articles.

227   Authors were also asked if their study was a preliminary study and if it was a resubmission of an article
228   originally sent to another journal. It would seem authors wishing to publish preliminary data from an
229   ongoing study might find the megajournal format attractive given the review criteria are limted to the
230   soundness of the methodology.About a quarter of the authors in BMJ Open, PLOS ONE and SAGE Open
231   indicated their manuscript did in fact describe preliminary results. Interestingly only about 10% of the
232   authors publishing in PeerJ indicated this was the case. One might think PeerJ with its membership model
233   and very rapid submission to first decision time would be attractive to authors publishing preliminary
234   work but as yet, that does not seem to be a significant source of manuscripts for the journal.

235   These journals do seem to attract a significant number of resubmissions. As noted two thirds of the BMJ
236   Open authors indicated their article was a resubmission of a manuscript rejected by another journal. There
237   were spontaneous comments from 11 authors indicating they were encouraged to resubmit to BMJ Open
238   after rejection by another BMJ journal. As noted above, BMJ does have a policy that upon request of the
239   author, manuscripts not accepted by other BMJ journals will automatically be considered by BMJ Open. It
240   appears this policy may account for many of the BMJ Open publications.

241   Just under half of the authors from PLOS ONE and SAGE Open indicated their publications were
242   resubmissions. One author from each of these journals also spontaneously stated they were encouraged by
243   the editor of another journal from the same publisher to submit to their megajournal after rejection. PeerJ
244   had the lowest percentage of authors indicating their articles were resubmissions at 37%. While it may be
245   an unrelated fact, PeerJ is not part of a larger publishing house. Since it is common for journals to have
246   rejections rates well above 50%, it is not surprising many of the articles published in megajournals are
247   resubmissions of manuscripts previously sent to another journal. While it appears that in at least that some
248   publishers are steering manuscripts that may be sound research but may not be of interest to their more
249   selective journals to their megajournal. A high percentage of authors are choosing a megajournal for their
250   initial submission. The quality of the journal and the speed of the review/publication process were the two
251   factors rated highly across all four journals in the authors' decision to publish in the megajournal. The
252   APC was a negative factor for a portion of the authors, particularly PLOS ONE and BMJ Open which
253   have considerably higher fees. Being open access was one of the more important factors for PeerJ authors
254   as well as SAGE Open authors but less so for the authors of the other two journals.

255   The impact factor was an important positive consideration for PLOS ONE and BMJ Open, the two
256   journals that currently have an impact factor. Phil Davis (2014) in a recent post on the Scholarly Kitchen
257   blog considered the possibility that a decline in PLOS ONE submissions in February 2014 might be
258   related to the decline in the journal's impact factor. A few PLOS ONE authors expressed concerns in the
259   comments that PLOS ONE's impact factor appears to be declining. Since impact is such an important
260   factor for a considerable number of authors publishing in PLOS ONE, a decline in impact could
261   conceivably impact on submissions particularly if authors feel there is a likelihood of continued decline. It
262   should be noted the vast majority of PLOS ONE authors indicated they were very likely to submit
263   manuscripts to the PLOSE ONE or a similar journal in the future.l. Time will tell whether the February
264   2014 decline was an anomaly or will continue.

265   As one might expect, grants were the largest source of funding for APCs among the biomedical journals. It
266   was far less common for SAGE Open authors where the vast majority of authors used personal funds.
267   SAGE recently reduced theSAGE One APC to 99 USD, perhaps influenced by the fact their authors are
268   largely self-funding publication and would naturally be very sensitive the price of an APC. While
269   considerably lower, around a third of the PeerJ authors paid their membership fee out of personal funds.

270 Although a biomedical journal, PeerJ's membership fee is fairly low and may attract authors who are
271 publishing unfunded research and might otherwise submit to a journal that does not require a publication
272 fee. A large percentage of PLOS ONE and even more significantly BMJ Open authors used
273 departmental/institutional discretionary funding or institutional funding based on a policy of funding
274 APCs. About 25% of the SAGE Open authors also were able to fund publication with these sources. PeerJ
275 has implemented institutional memberships with a number of universities and other organizations but very
276 few of the authors who responded to the survey indicated they were able to take advantage of these
277 agreements. PeerJ has had in place a fee waiver during a significant portion of the period data were
278 collected. A little over a quarter of the authors were able to take advantage of publishing their manuscript
279 without having to obtain a paid membership.

280 Authors are funding the cost of publishing in a variety of ways. As one might expect, covering a fee of
281 around 1,350 USD or for some megajournals even higher is an issue for authors without grant or some
282 form of institutional funding. Where it is possible to maintain APCs or membership fees in the range of
283 100 USD, it appears many authors are willing to pay the fees themselves. Given the relatively modest
284 sample size I did not try to breakdown the data by country. While a fee of 100 USD might be affordable
285 for researchers in the US or Western Europe, that may not be the case in other parts of the world.

286 Clearly the cost of publications fees is an issue for researchers in the social sciences and this pressure has
287 results in substantially lower publications fees for SAGE One. There seems although a high APC was an
288 issue for some of the respondents who published in PLOS ONE and BMJ Open these journals are
289 attracting a large number of submissions and the pressure to keep publication fees low does not appear to
290 be as great as in the social sciences one would assume because of the availability of funding either through
291 granting agencies or the authors' institution.

292 The authors overwhelmingly indicated they would likely publish again in the same or another similar
293 megajournal. Most of the comments were written were also positive. PeerJ authors seemed to be
294 particularly satisfied with their publishing experience. As a new journal, the staff may be particularly
295 sensitive to providing good service to the authors. As noted above a few of the PLOS ONE and SAGE
296 Open authors complained about exceptionally long review times. It appears that these journals
297 occasionally experience difficulty locating appropriate review editors and/or reviewers. While this can be
298 a challenge for any journal editor, having a very broad scope would likely increase the difficulty of finding
299 qualified experts for peer review. Given the tremendous volume of PLOS ONE submission it would not be
300 surprising if they occasionally have difficulty finding appropriate review teams. While some authors were
301 clearly frustrated with the length of the review process it appears most authors were reasonably satisfied
302 given their willingness to submit to the journals or at least the journal format in the future.

303 What seems clear is the reputation of the journal and the quality of the service they provide are major
304 factors in the choice of where to publish. For some megajournals and likely to a greater extent in some
305 fields the impact factor as a proxy for quality is extremely important. Although journals have always
306 competed for the best manuscripts, the APC funding model or a membership model such as used by PeerJ
307 increases the importance of journals attracting submissions. Authors rather than readers or libraries as
308 their proxy have become the customers with this business model. In this sense, one might expect an
309 increasing focus by publishers on enhancing the services provided to authors such as fast efficient review
310 and user friendly submission systems.

311 The impact on author fees appears to be more complex. In fields where funding for publishing is more
312 readily available the pressure on publishers to lower APCs may be less or nearly nonexistent for journals
313 with high impact factors and excellent reputations for quality. In fields such as social science where
314 authors often self-fund publishing charges, price is an important factor in the decision where to publish
315 and there appears to be real competitive pressure to keep author fees low. Grantors, universities and other
316 agencies that provide funding for their researchers' author fees will need to find ways to balance
317 subsidizing their researchers' publication fees while encouraging them to consider price as well as quality

318   or impact in the choice of journals in which to publish. If not, there will likely be considerable inflation in
319   author fees for the more prestigious journals in fields such as biomedicine where research funding is
320   readily available.

321   Megajournals are becoming an established part of scientific publishing. The results of this survey seem to
322   suggest that a broad range of authors are choosing to publish in this format and in general are satisfied
323   with their experience.
