In recent years, the use of lectins for screening of potential biomarkers has gained increased importance in cancer research, given the development in glycobiology that highlights altered structural changes of glycans in cancer associated processes. Lectins, having the properties of recognizing specific carbohydrate moieties of glycoconjugates, have become an effective tool for detection of new cancer biomarkers in complex bodily fluids and tissues. The specificity of lectins provides an added advantage of selecting peptides that are differently glycosylated and aberrantly expressed in cancer patients, many of which are not possibly detected using conventional methods because of their low abundance in bodily fluids. When coupled with mass spectrometry, research utilizing lectins, which are mainly from plants and fungi, has led to identification of numerous potential cancer biomarkers that may be used in the future. This article reviews lectin-based methods that are commonly adopted in cancer biomarker discovery research.

15 **Abstract**

16 In recent years, the use of lectins for screening of potential biomarkers has gained increased  
17 importance in cancer research, given the development in glycobiology that highlights altered  
18 structural changes of glycans in cancer associated processes. Lectins, having the properties  
19 of recognizing specific carbohydrate moieties of glycoconjugates, have become an effective  
20 tool for detection of new cancer biomarkers in complex bodily fluids and tissues. The  
21 specificity of lectins provides an added advantage of selecting peptides that are differently  
22 glycosylated and aberrantly expressed in cancer patients, many of which are not possibly  
23 detected using conventional methods because of their low abundance in bodily fluids. When  
24 coupled with mass spectrometry, research utilizing lectins, which are mainly from plants and  
25 fungi, has led to identification of numerous potential cancer biomarkers that may be used in

26 the future. This article reviews lectin-based methods that are commonly adopted in cancer  
27 biomarker discovery research.

28

## 29 **Biology of lectins**

30 Lectins are carbohydrate binding proteins which are found ubiquitously in nature. The term  
31 ‘lectin’ originates from the Latin word *legere*, which means to choose or to select (*Boyd and*  
32 *Shapleigh, 1954*). By binding to carbohydrates, lectins serve diverse biological functions.  
33 Plant lectins, which typically cause agglutination of certain animal cells, play important roles  
34 in defense against invasion of virus, bacteria or fungi (*Dias et al., 2015*). They are also  
35 believed to mediate symbiosis relationship between plants and microorganisms (*De Hoff et*  
36 *al., 2009*), and some may be involved in regulatory and signaling pathways in plant cells  
37 (*Chen et al., 2002*).

38 Lectins have initially been classified based on their binding to different glycan structures.  
39 They were categorized either as galactose, *N*-acetylglucosamine (GlcNAc), *N*-  
40 acetylgalactosamine (GalNAc), glucose, L-fucose, mannose, maltose, sialic acid-specific or  
41 complex glycan-binding lectins (*Lis and Sharon, 1986*). Later, they were also classified  
42 based on the characteristics and numbers of their carbohydrate binding domains, namely  
43 merolectins, hololectins, chimerolectins and superlectins (*Peumans et al., 2001*). With the  
44 emergence of detailed structural properties of lectins being elucidated via the advancement of  
45 technology, this classification further evolved into that based on distinct protein folding,  
46 domains/structural similarities and evolutionary-relatedness of proteins (*Peumans et al.,*  
47 *2001*). Via this categorization, 12 different lectin families, which include *Agaricus bisporus*

48 agglutinin homologues, amarantins, class V chitinase homologues with lectin activity,  
 49 cyanovirin family, *Euonymus europaeus* agglutinin family, *Galanthus nivalis* agglutinin  
 50 family, jacalins, lysin motif domain, nictaba family, proteins with hevein domains, proteins  
 51 with legume lectin domains and ricin-B family (*Van Damme et al., 2008*), have been derived.

52 Ricin is believed to be the first lectin discovered in the seeds of the castor bean plant,  
 53 *Ricinus communis*, in 1888 (*Sharon and Lis, 2004*). Paradoxically, research on lectin only  
 54 flourished several decades subsequent to ricin's discovery after James Sumner successfully  
 55 purified a crystalline protein from jack bean (*Canavalia ensiformis*) in 1919. Sumner later  
 56 showed that the protein caused agglutination of cells such as erythrocytes and yeast. The  
 57 agglutinin, which is now known as concanavalin A or ConA, was also used for the first time  
 58 to demonstrate binding of lectins to carbohydrate. To date, there are more than a thousand  
 59 plant species that have been reported to possess lectins. Most of these lectins are in  
 60 abundance in seeds (*Lis and Sharon, 1986; Benedito et al., 2008*), whilst some are found in  
 61 leaves, roots, flower, sap, barks, rhizomes, bulbs, tubers and stems (*Dias et al., 2015*).  
 62 Because of their carbohydrate binding specificities, many lectins have been increasingly  
 63 applied in different areas of medical research and therapy (*Table 1*).

64

65 **Table 1** Summary of different applications of lectins in medical research and therapy

Lectin applications	Reference
Antibacterial agent	<i>Saha et al., 2014; Dias Rde et al., 2015</i>
Antifungal agent	<i>Klafke et al., 2013; Regente et al., 2014</i>
Antiparasitic agent	<i>Kobata-Kudo et al., 2005; Heim et al., 2015</i>

Antiviral agent	<i>Lusvarghi and Bewley, 2016; Monteiro and Lepenies, 2017</i>
Biomarker for disease detection and monitoring	<i>This review article</i>
Drug delivery	<i>Leong et al., 2011; Neusch et al., 2013</i>
Induction of immunological and inflammatory response	<i>Singh et al., 2011; Ditamo et al., 2016</i>
Inhibition of cancer cell adhesion	<i>Redondo and Alvarez-Pellitero, 2010; Siva et al., 2014</i>
Inhibition of cancer cell growth / antitumor agent	<i>Jebali et al., 2014; Quiroga et al., 2015; Dan et al., 2016</i>
Promotion of healing in cutaneous wounds	<i>Brustein et al., 2012; Coriolano et al., 2014</i>

## 68 **Cancer biomarker**

69 A biomarker is defined as “a characteristic that is objectively measured and evaluated as an  
70 indicator of normal biological processes, pathogenic processes or pharmacologic responses to  
71 a therapeutic intervention” (*Biomarkers Definition Working Group, 2001*). Hence, simple  
72 parameters from pulse and blood pressure to protein constituents of cells, tissues, blood and  
73 other biofluids are classified as biomarkers. Bodily fluids that have been mined for cancer  
74 biomarkers thus far include serum/plasma, urine, saliva and other tissue-specific fluids such  
75 as seminal fluid, cerebrospinal fluid, bone marrow aspirates, etc. Cancer biomarkers are  
76 useful for early detection, diagnosis and prognosis of the disease. They are also heavily  
77 relied on in management of patients, and assessment of pharmacodynamics of drugs, risk, as  
78 well as recurrence of the disease.

79 Efforts in the search for new cancer biomarkers remain active even in the present day.  
 80 Currently, there are only a handful of cancer biomarkers that are commonly being used in the  
 81 clinical setting (Table 2), most of which have been officially approved by the US Food and  
 82 Drug Administration (FDA) for clinical use (Füzéry *et al.*, 2013). More are definitely needed  
 83 for improved detection and diagnosis, particularly when the reliability of many of the FDA  
 84 approved biomarkers remains a problem due to their limited levels of sensitivity and  
 85 specificity. For example, CA-125 which is used as a biomarker for ovarian cancer, is also  
 86 often elevated in other cancers such as those of the breast (Norum *et al.*, 2001), lung (Salgia  
 87 *et al.*, 2001) and colon or rectum (Thomas *et al.*, 2015). Similarly, prostate specific antigen  
 88 (PSA), a tissue-specific serum protein that is used in the diagnosis of prostate cancer, is also  
 89 commonly increased in sera of patients with benign prostatic hyperplasia, thus, posing  
 90 difficulties in clinically differentiating the two different conditions (Barry, 2001; Thompson  
 91 *et al.*, 2004). These limitations, together with the recent development of various state-of-the-  
 92 art methodologies including genomics, proteomics and bioinformatics, have consequentially  
 93 propelled research towards identification of new cancer biomarkers that are more sensitive  
 94 and specific.

95

96 **Table 2** List of commonly used tumor markers in clinical practice.

Biomarker	Glycosylated	Cancer type	Specimen	Clinical use
Alpha-feto protein (AFP)	Yes	Testicular	Serum/plasma; Amniotic fluid <sup>1</sup>	Management of cancer
AFP-L3%	Yes	Hepatocellular	Serum	Risk assessment
Beta-2-microglobulin (B2M)	Yes	Blood cells	Serum, Urine, Cerebrospinal fluid	Monitoring progression and recurrence
Bladder tumor-	Unknown	Bladder	Urine	Monitoring disease

associated antigen				
CA 15-3	Yes	Breast	Serum/plasma	Monitoring disease; Response to therapy
CA 19-9	Yes <sup>2</sup>	Pancreatic	Serum/plasma	Monitoring disease
CA 27-29	Yes	Breast	Serum	Monitoring disease; Response to therapy
CA 125	Yes	Ovarian	Serum/plasma	Monitoring disease; Response to therapy
Carcinoembryonic antigen (CEA)	Yes	Colon	Serum/plasma	Monitoring disease; Response to therapy
c-Kit	Yes	Gastrointestinal stromal tumors	Tissue	Detection of tumor; Patient selection
EpCAM, CD45, cytokeratins 8, 18+, 19+	Yes	Breast	Whole blood	Monitoring progression and survival
Epidermal growth factor receptor (EGFR)	Yes	Colon	Tissue	Therapy selection
Estrogen receptor (ER)	Yes	Breast	Tissue	Prognosis; Response to therapy
HER2/NEU	Yes	Breast	Serum; Tissue	Monitoring progression; Therapy selection
Human chorionic gonadotropin	Yes	Testicular	Serum	Staging of cancer
Human epididymis protein 4 (HE4)	Yes	Ovarian	Serum	Monitoring progression and recurrence
Fecal occult blood (haemoglobin)	Yes	Colorectal	Feces	Detection of tumor
Fibrin/fibrinogen degradation product (DR-70)	Yes	Colorectal	Serum	Monitoring disease
Free prostate specific antigen	Yes	Prostate	Serum	Screening for disease
Nuclear mitotic apparatus protein (NuMA, NMP22)	Yes	Bladder	Urine	Diagnosis and monitoring disease
p63 protein	No	Prostate	Tissue	Differential diagnosis
Plasminogen activator inhibitor (PAI-1)	Yes	Breast	Tissue	Monitoring disease; Therapy selection

Progesterone receptor (PR)	Yes	Breast	Tissue	Therapy selection
Pro2PSA	Yes	Prostate	Serum	Discriminating cancer from benign disease
Thyroglobulin (Tg)	Yes	Thyroid	Serum/plasma	Monitoring disease
Total PSA	Yes	Prostate	Serum	Diagnosis and monitoring disease
Urokinase plasminogen activator (uPA)	Yes	Breast	Tissue	Monitoring disease; Therapy selection

97 <sup>1</sup>Also used in prenatal diagnosis of birth defects, a non-cancer application.

98 <sup>2</sup>A tetrasaccharide carbohydrate that is usually attached to *O*-glycans on the surface of cells.

113

Amongst bodily fluids that have been mined for cancer biomarkers, serum/plasma is most popular. Serum or plasma has the advantage of being routinely sampled in clinical investigations. However, the extreme complexity and broad dynamic range of protein abundance in serum and plasma pose a formidable challenge in research screening for potential cancer biomarkers, which mostly comprise low abundance glycoproteins. Because of this, many cancer biomarker exploratory studies involving serum or plasma often involved enrichment and/or pre-fractionation of the samples using techniques such as immunodepletion (*Preito et al., 2014*), immunoprecipitation (*Lin et al., 2013*) and size-exclusion chromatography (*Hong et al., 2012*). However, the use of such techniques, despite their wide applications in biomarker discovery investigations, is generally unable to make a significant difference in unmasking proteins of low abundance [*Polaskova et al., 2010*], and may result in concomitant loss of non-targeted proteins (*Bellei et al., 2011*).

## 114 **Applications of lectins in cancer biomarker discovery research**

115 Interestingly, the majority of cancer biomarkers that are currently being used in the clinical  
116 settings are glycoproteins, which are structurally altered in their glycan moieties and  
117 aberrantly expressed (*Henry and Hayes, 2012*). However, only alpha-fetoprotein (AFP) and  
118 CA15-3 are clinically monitored for their glycan changes in the therapy for hepatocellular  
119 carcinoma and breast cancer, respectively. The other cancer biomarkers are being monitored  
120 for their total protein levels (*Kuzmanov et al., 2013*). Indeed, changes in glycosylation are  
121 believed to be a main feature in oncogenic transformation as glycans are known to be  
122 continuously involved in cancer evolving processes, such as cell signaling, angiogenesis,  
123 cell-matrix interactions, immune modulation, tumor cell dissociation and metastasis.  
124 Glycosylation changes that are commonly associated with cancer transformation include  
125 sialylation, fucosylation, increased GlcNAc-branching of *N*-glycans, and overexpression of  
126 truncated mucin-type *O*-glycans (*Pinho and Reis, 2015*). Hence, it is not surprising that  
127 lectin-based approaches are becoming more popular in studies screening for novel cancer  
128 biomarkers. [Table 3](#) shows a list of lectins that have been used in cancer biomarker  
129 discovery research. In the following sections of this review, the applications of lectins in  
130 cancer biomarker discovery, including immobilized lectin affinity chromatography, enzyme-  
131 linked lectin assay, lectin histochemistry, lectin blotting and lectin array, are addressed. For  
132 lectin-based biosensor analysis, readers are recommended to refer to separate review articles  
133 (*Pihiková et al., 2015; Coelho et al., 2017*).

134

135

136

137 **Table 3** List of lectins used in cancer biomarker discovery research.

Lectin	Abbreviation	Specificity	Glycan Linkage	References
African legume ( <i>Griffonia (Bandeiraea) simplicifolia</i> ) lectin-I	GSLI (BSLI)	$\alpha$ -Gal; $\alpha$ -GalNAc	O-linked	<i>Lescar et al., 2002</i>
Asparagus pea ( <i>Lotus tetragonolobus</i> ) lectin	LTL	Fuc $\alpha$ 1-3(Gal $\beta$ 1-4)GlcNAc, Fuc $\alpha$ 1-2Gal $\beta$ 1-4GlcNAc	N-linked	<i>Pereira and Kabat, 1974; Yan et al., 1997</i>
Koji ( <i>Aspergillus oryzae</i> ) lectin	AOL	$\alpha$ 1,6-fucosylated	N-linked	<i>Matsumura et al., 2007</i>
Castorbean ( <i>Ricinus communis</i> ) agglutinin	RCA	Gal $\beta$ 1-4GlcNAc; terminal $\beta$ -D-Gal	N-linked	<i>Harley and Beevers 1986; Wang et al., 2011</i>
Champedak ( <i>Artocarpus integer</i> ) galactose binding lectin	CGB	Gal; GalNAc	O-linked	<i>Hashim et al., 1991; Gabrielsen et al., 2014</i>
Champedak ( <i>Artocarpus integer</i> ) mannose binding lectin	CMB	Man	N-linked	<i>Lim et al., 1997; Gabrielsen et al., 2014</i>
Daffodil ( <i>Narcissus pseudonarcissus</i> ) lectin	NPL	$\alpha$ -Man, prefers polymannose structures containing $\alpha$ -1,6 linkages	N-linked	<i>Kaku et al., 1990; Lopez et al., 2002</i>
Elderberry ( <i>Sambucus nigra</i> ) agglutinin	SNA	Neu5Ac $\alpha$ 2-6Gal(NAc)-R	N- and O-linked	<i>Shibuya et al., 1987; Silva et al., 2017</i>
Gorse or furze ( <i>Ulex europaeus</i> ) seed agglutinin-I	UEA-I	Fuc $\alpha$ 1-2Gal-R	N- and O-linked	<i>Holthofer et al., 1982; Raj Bharath and Krishnan, 2016</i>
Jackbean ( <i>Canavalia ensiformis</i> ) lectin	ConA	$\alpha$ -Man; $\alpha$ -Glc	N-linked	<i>Percin, et al., 2012</i>
Jackfruit ( <i>Artocarpus heterophyllus</i> ) lectin	Jacalin	Gal; GalNAc	O-linked	<i>Kabir, 1995; Jagtap and Bapat, 2010</i>
Lentil ( <i>Lens culinaris</i> ) hemagglutinin	LcH	Man; Glc (Affinity enhanced with $\alpha$ -Fuc attached to N-acetylchitobiose)	N-linked	<i>Howard et al., 1971; Chan et al., 2015</i>
Amur maackia ( <i>Maackia amurensis</i> )	MAL II	Sia $\alpha$ 2-3Gal $\beta$ 1-4GlcNAc; Sia $\alpha$ 2-	N- and O-linked	<i>Konami et al., 1994;</i>

lectin II		3Gal $\beta$ 1-3GalNAc		<i>Geisler and Jarvis, 2011</i>
Orange peel fungus ( <i>Aleuria aurantia</i> ) lectin	AAL	Fuc $\alpha$ 1-6GlcNAc; Fuc $\alpha$ 1-3LacNAc	<i>N</i> - and <i>O</i> -linked	<i>Hassan et al., 2015</i>
Peanut ( <i>Arachis hypogaea</i> ) agglutinin	PNA	Gal $\beta$ 1-3GalNAc; Gal	<i>O</i> -linked	<i>Chacko and Appukuttan, 2001; Vijayan, 2007</i>
Chinese green dragon ( <i>Pinellia pedatisecta</i> ) agglutinin	PPA	Man	<i>N</i> -linked	<i>Li et al., 2014</i>
Poke weed ( <i>Phytolacca americana</i> ) mitogen lectin	PWM	GlcNAc oligomers	<i>N</i> -linked	<i>Kino et al., 1995; Ahmad et al., 2009</i>
Red kidney bean ( <i>Phaseolus vulgaris</i> ) lectin	PHA-L	Bisecting GlcNAc	<i>N</i> -linked	<i>Kaneda et al., 2002; Movafagh et al., 2013</i>
Thorn-apple ( <i>Datura stramonium</i> ) lectin	DSL	(GlcNAc $\beta$ 4) <sub>n</sub>	<i>N</i> -linked	<i>Yamashita et al., 1987; Abbot et al., 2010</i>
Wheat germ ( <i>Triticum vulgaris</i> ) agglutinin	WGA	GlcNAc $\beta$ 1-4GlcNAc $\beta$ 1-4GlcNAc; Neu5Ac	<i>N</i> -linked	<i>Nagata and Burger, 1972; Parasuraman et al., 2014</i>
White button mushroom ( <i>Agaricus bisporus</i> ) lectin	ABL	GalNAc; Gal $\beta$ 1,3GalNAc (T antigen); sialyl-Gal $\beta$	<i>O</i> -linked	<i>Nakamura-Tsuruta et al., 2006; Hassan et al., 2015</i>

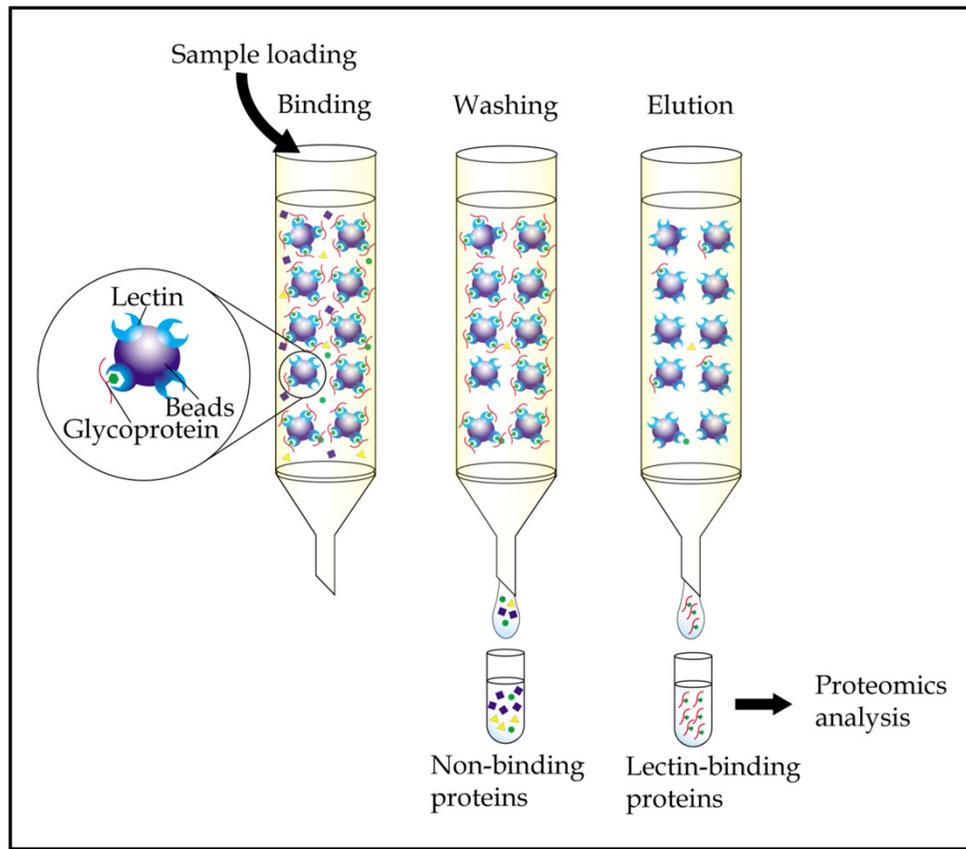

138

139

140      **Immobilized-lectin affinity chromatography**

141      Immobilized-lectin affinity chromatography is a method for separation of glycoproteins  
142      based on a highly specific interaction between a lectin, which is immobilized onto a chosen  
143      matrix, and its carbohydrate ligands (*Hage et al., 2012*). The technique, when complemented  
144      with mass spectrometry analysis, provides a useful tool in research aiming to identify  
145      potential cancer biomarkers ([Figure 1](#)). By comparing bodily fluid samples of control  
146      subjects with those from patients with cancer, glycoproteins that are aberrantly expressed or  
147      differently glycosylated from the resulting glycoprotein-enriched eluates can be easily  
148      identified. Immobilized-lectin affinity chromatography is currently one of the most widely  
149      employed techniques for enrichment of glycoproteins in cancer biomarker research.

150

151

152 **Figure 1 General workflow of immobilized-lectin affinity chromatography.** Bodily fluid  
 153 of cancer patients can be assayed for potential cancer biomarkers by running it through a  
 154 chromatography column packed with a gel matrix that is conjugated with a lectin of interest.  
 155 Non-binding proteins are then washed out, whilst bound glycoproteins are eluted using specific  
 156 carbohydrate solutions. The lectin bound glycoproteins are finally identified using proteomics  
 157 analysis.

158

159 By using immobilized-ConA, followed by separation by 2-dimensional gel  
 160 electrophoresis (2-DE), *Rodriguez-Pineiro et al. (2004)* were able to profile serum samples  
 161 of patients with colorectal cancer and showed significant altered expression of several *N*-  
 162 glycosylated proteins that were identified by mass spectrometry. These included up-  
 163 regulated expression of haptoglobin and lowered expression of antithrombin-III, clusterin,

164 inter-alpha-trypsin inhibitor heavy chain H4, beta-2-glycoprotein I and coagulation factor  
165 XIII B chain in the colorectal cancer patients relative to healthy donors. Similarly,  
166 *Seriramalu et al. (2010)* reported the lowered expression of complement factor B and alpha-2  
167 macroglobulin in patients with nasopharyngeal carcinoma relative to controls using the  
168 champedak mannose binding lectin. In the case of *O*-glycosylated proteins, considerable  
169 studies have been reported using champedak galactose binding (CGB) lectin, which has a  
170 unique characteristic of binding to the *O*-glycan structures of glycoproteins (*Abdul Rahman*  
171 *et al., 2002*) in serum and urine samples. Cancers that have been investigated using  
172 immobilized-CGB lectin include endometrial cancer (*Mohamed et al., 2008*) and prostate  
173 cancer (*Jayapalan et al., 2012*). However, most of the serum and urine *N*- and *O*-  
174 glycosylated proteins that were isolated using the immobilized-lectin affinity  
175 chromatography are not directly cancer associated but the body's highly abundant acute-  
176 phase reactant proteins (*Pang et al., 2010*).

177 More recently, analyses of enriched glycopeptide eluates of immobilized-lectin affinity  
178 chromatography for identification of site-specific glycosylation using mass spectrometry  
179 techniques have been reported in studies in search of potential cancer biomarkers.  
180 Enrichment of core fucosylated peptides using *Lens culinaris* agglutinin (LCA) after trypsin  
181 digestion of glycoproteins, followed by endo F3 partial deglycosylation and nano LC-  
182 MS/MS methodologies, has led to identification of glycopeptides that can potentially be used  
183 as diagnostic biomarkers for pancreatic cancer (*Tan et al., 2015*). Similarly, enrichment of  
184 trypsin-digested glycopeptides using *Aleuria aurantia* lectin (AAL) that was immobilized  
185 onto agarose gel, followed by analysis using LC/MS, has resulted in identification of alpha-  
186 1-acid glycoprotein with multi-fucosylated tetraantennary glycans as a potential marker for

187 hepatocellular carcinoma (*Tanabe et al., 2016*). In another study, the *Sambucus niagra*  
188 agglutinin (SNA) affinity column was used to separate various glycoforms of serum PSA  
189 according to the types of sialic acid linkages (*Llop et al., 2016*). This has resulted in  
190 identification of  $\alpha$ 2, 3-sialylated PSA as a marker for discriminating patients with high-risk  
191 prostate cancer from those with benign prostatic hyperplasia and low-risk prostate cancer,  
192 with higher levels of sensitivity and specificity.

193 Another variant of immobilized-lectin affinity chromatography used in cancer biomarker  
194 research is multi-lectin affinity chromatography. Since no single lectin is able to isolate the  
195 complete complement of a glycoprotein, a multi-lectin affinity chromatography is gaining  
196 popularity because of its greater coverage and depth of analyses. Using a combination of  
197 four different types of lectins, including ConA, SNA, *Phaseolus vulgaris* agglutinin (PHA)  
198 and *Ulex europaeus* agglutinin (UEA), for sequential multi-lectin affinity chromatography in  
199 silica-based microcolumns and nano-LC/MS/MS for identification of proteins, *Madera et al.*  
200 (*2007*) successfully profiled glycoproteins from microliter volumes of serum. Along the  
201 same line but using ConA, wheat germ agglutinin (WGA) and jacalin that were integrated  
202 into an automated HPLC platform and immuno-depleted serum samples, *Zeng et al. (2011)*  
203 demonstrated a comprehensive detection and changes in the abundances of post-  
204 translationally modified breast cancer-associated glycoproteins. To facilitate a cascading  
205 flow of samples from column to column for simultaneous and efficient capturing and  
206 enrichment of fucosylated proteins, *Selvaraju and El Rassi (2013)* developed of a platform,  
207 which comprised multi-lectin columns driven by HPLC pumps for elucidating differential  
208 expression of serum fucose between cancer-free and breast cancer subjects. This method  
209 surpasses issues such as loss of samples due to sample preparation and processing (e.g.,

210 dilution) as well as other experimental biases that commonly occur when using other  
211 techniques.

212 Recently, *Miyamoto et al. (2016)* reported a comprehensive proteomic profiling of ascites  
213 fluid obtained from patients with metastatic ovarian cancer enriched by differential binding  
214 to multiple lectins, including ConA, AAL and WGA. Alpha-1-antichymotrypsin, alpha-1-  
215 antitrypsin, ceruloplasmin, fibulin, fibronectin, hemopexin, haptoglobin and lumican  
216 appeared more abundant in ascites of the patients compared to controls. Further glycopeptide  
217 analysis identified unusual *N*- and *O*-glycans in clusterin, fibulin and hemopexin  
218 glycopeptides, which may be important in metastasis of ovarian cancer. Similar use of multi-  
219 lectin affinity chromatography for enrichment of *N*-linked glycoproteins by *Qi et al. (2014)*  
220 has successfully identified human liver haptoglobin, carboxylesterase 1 and procathepsin D  
221 as candidate biomarkers associated with development and progression of hepatocellular  
222 carcinoma. Whilst the concentrations of human liver haptoglobin and carboxylesterase 1  
223 were consistently lower, higher concentration of procathepsin D was detected in the liver  
224 cancer tissues. Further in-depth analysis projected the promising use of procathepsin D as  
225 serological biomarker for diagnosis of hepatocellular carcinoma.

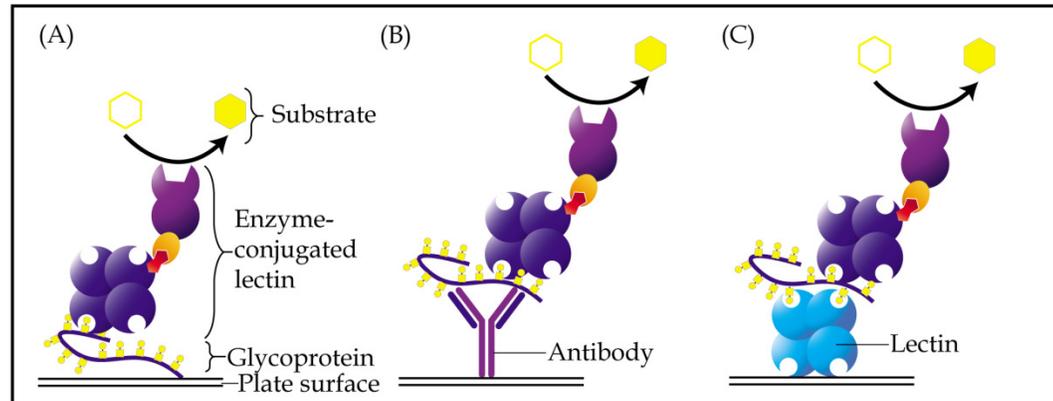

226

### 227 **Enzyme-linked lectin assay**

228 Enzyme-linked lectin assay is a method that adopts the principle of enzyme-linked  
229 immunosorbent assay but uses lectin as one of the reagents instead of antibody. This method  
230 was introduced by *McCoy Jr. et al. (1983)* in the early eighties. In a direct assay, samples  
231 that contain glycoconjugates may be coated directly onto the wells of a microtiter plate,

232 followed by addition of an enzyme-conjugated lectin, which will then bind to their glycan  
233 structures (Figure 2, panel A). The enzyme converts a colorless substrate solution to a  
234 colored product, that is then measured using a spectrophotometer, and whose intensity is  
235 used to estimate the levels of the coated glycoconjugates. Depending on the structures of  
236 glycans that need to be detected, specific lectins are carefully selected. Enzyme-linked lectin  
237 assay has been used in a plethora of research including those of cancer biomarkers  
238 (*Kuzmanov et al., 2013*). It is easy to perform, very cost effective and requires minute  
239 amounts of samples. One drawback of the direct enzyme-linked lectin assay is that  
240 glycoproteins that are detected may not be identifiable unless it is coupled with proteomics  
241 analysis or antibody detection.

242

243

244 **Figure 2** Different approaches of enzyme-linked lectin assay. (A) In the direct assay,  
245 coating of samples is performed directly onto the surface of a microtiter plate, followed by  
246 addition of enzyme-conjugated lectin. (B) In the hybrid assay, antibody is instead coated onto  
247 the plate to capture specific glycoproteins of interest, prior to addition of the enzyme-  
248 conjugated lectin. (C) Sandwich enzyme-linked lectin assay is an alternative method involving  
249 two different lectins. The first lectin is coated onto plates and used as a capturing reagent,  
250 whilst the second lectin is used as detection reagent. For all the aforementioned methods,

251 glycoproteins are usually detected using a lectin that is conjugated to an enzyme, which then  
252 converts a specific substrate into a colored product.

253

254 Based on their earlier study that identified a predominantly high molecular weight  
255 glycoprotein that binds to peanut lectin (PNA) in the sera of patients with pancreatic cancer,  
256 *Ching and Rhodes (1989)* developed a direct enzyme-linked PNA assay for diagnosis of  
257 pancreatic cancer. Results obtained from the lectin-based assay were apparently found to be  
258 comparable with those derived from using CA19-9 radioimmunoassay, in terms of sensitivity  
259 and specificity for pancreatic cancer. In another study, *Reddi et al. (2000)* reported the use of  
260 similar enzyme-linked PNA assay to estimate the levels of Thomsen-Friedenreich antigen  
261 (T-Ag) in sera of patients with squamous cell carcinoma of the uterine cervix, before and  
262 after radiotherapy. The study demonstrated significantly higher levels of T-Ag in the sera of  
263 the uterine cervical cancer patients compared to normal individuals, and that the expression  
264 of PNA-binding T-Ag were directly proportional to the aggressiveness of the cancer. In a  
265 study by *Dwek et al., (2010)*, the specificity of UEA-1 lectin to  $\alpha$ 1,2-linked fucose sites was  
266 capitalized for detection of fucosylated serum free PSA in a direct enzyme-linked lectin  
267 assay. Their results demonstrated higher levels of fucosylated serum free PSA in patients  
268 with prostate cancer compared to those with benign prostatic hyperplasia.

269 Aside from sera, direct enzyme-linked lectin assay has also been used in the analysis of  
270 tissue lysate glycoproteins. In a recent study of breast cancer tissue lysates of different  
271 stages, *Wi et al. (2016)* demonstrated increased interaction with ConA, *Ricinus communis*  
272 Agglutinin I, AAL and *Maackia amurensis* lectin II (MAL II), relative to normal tissue  
273 specimen of the same subjects. This is generally interpreted to show enhanced

274       mannosylation, galactosylation, sialylation and fucosylation of glycoproteins in the breast  
275       cancer tissues. In another study, *Kim et al. (2014)* have shown lower levels of fucosylation  
276       and sialylation of cytosolic intracellular glycoproteins in cancerous human cervical tissues  
277       compared to normal tissue specimens from the same subjects using AAL and SNA lectins,  
278       respectively. However, the levels of mannosylation, which was assayed using ConA, were  
279       not significantly different between cancer tissues and normal specimens.

280             Subtle changes to the classical enzyme-linked lectin assay protocol have been introduced  
281       over the years. An example is the combined use of antibody with lectin to enable detection  
282       of glycosylation on a specific protein (*Kim et al., 2008*). In this case, an antibody may be  
283       coated directly onto the wells of a microtiter plate, which will allow pre-capturing of a  
284       protein of interest from complex samples (*Figure 2*, panel B). A lectin is then added and let  
285       on to bind with the glycan structures of the protein. In this method, prior purification of a  
286       glycoprotein is not needed as the antibody utilized specifically isolates the protein of interest  
287       from within the samples. This method is also more suitable for glycoprotein antigens, which  
288       are generally hydrophilic and cannot be well-coated onto a microtiter plate. The  
289       disadvantage of this approach is that a lectin may directly interact with glycan chains of the  
290       antibody used, which would then result in high background readings.

291             To solve the issue of the non-specific direct interaction of lectin to antibodies in enzyme-  
292       linked lectin assays, *Takeda et al. (2012)* have instead used the Fab fragment of anti-human  
293       haptoglobin IgG antibody and biotinylated AAL lectin for sandwich detection of fucosylated  
294       haptoglobin. Their results showed that the levels fucosylated haptoglobin were significantly  
295       associated with overall and relapse-free survival, distant metastasis, clinical stage, and  
296       curability of patients with colorectal cancer. When Kaplan-Meier analysis was performed on

297 patients after more than 60 months of surgery, positive cases of fucosylated-haptoglobin  
298 showed poor prognosis compared with fucosylated-haptoglobin negative cases. This leads to  
299 the suggestion of fucosylated haptoglobin as a prognostic marker in addition to CEA for  
300 colorectal cancer. Along the same line, *Jin et al. (2016)* have instead used protein A as the  
301 capturing reagent and AAL lectin as detection probe, for assessment of fucosylated  
302 circulating antibodies in cervical intraepithelial neoplasia and cervical cancer. Significantly  
303 lower levels of fucosylated circulating immunoglobulins were shown in female patients with  
304 cervical cancer compared to those with cervical intraepithelial neoplasia or normal subjects.

305 In a reverse contrast strategy, *Wu et al. (2013)* have used SNA lectin to capture sialylated  
306 glycoproteins and biotinylated-antibodies to detect clusterin, complement factor H,  
307 hemopexin and vitamin D-binding protein to validate the altered levels of the respective  
308 glycoproteins in sera of patients with ovarian cancer. The results were consistent with their  
309 data that was previously generated using isobaric chemical labeling quantitative strategy. In  
310 a similar strategy, *Liang et al. (2015)* have used *Bandeiraea (Griffonia) simplicifolia*-I (BSI),  
311 AAL and Poke weed mitogen (PWM) lectins as capturing reagents and biotinylated anti-  
312 human  $\alpha$ -1-antitrypsin polyclonal antibody in a sandwich enzyme-linked lectin combination  
313 assay to validate results of their lectin microarray analysis of serum samples of patients with  
314 lung cancer. While galactosylated  $\alpha$ -1-antitrypsin was shown to demonstrate remarkable  
315 discriminating capabilities to differentiate patients with non-small-cell lung cancer from  
316 benign pulmonary diseases, their fucose- and poly-LacNAc-containing counterparts may be  
317 used to discriminate lung adenocarcinoma from benign diseases or other lung cancer  
318 subtypes, and small-cell lung cancer from benign diseases, respectively.

319 In a slightly different context, *Lee et al. (2013)* have developed a sandwich enzyme-  
320 linked assay that uses two different lectins that both bind to *O*-glycan structures of  
321 glycoproteins (*Figure 2*, panel C). The assay, which uses CGB lectin as capturing coated  
322 reagent and enzyme-conjugated jacalin as detection probe, was primarily designed to  
323 measure the levels of mucin-type *O*-glycosylated proteins in serum samples. When the assay  
324 was applied on sera of patients with stage 0 and stage I breast cancer as well as those of  
325 normal control women, significantly higher levels of *O*-glycosylated proteins were detected  
326 in both groups of breast cancer patients (*Lee et al., 2016*). The specificity and sensitivity of  
327 the assay were further improved when the same serum samples were subjected to perchloric  
328 acid enrichment prior to the analysis. Further characterization of the perchloric acid isolates  
329 by gel-based proteomics detected significant altered levels of plasma protease C1 inhibitor  
330 and proteoglycan 4 in both stage 0 and stage I breast cancer patients compared to the  
331 controls. Their data suggests that the ratio of the serum glycoproteins may be used for  
332 screening of early breast cancer.

333

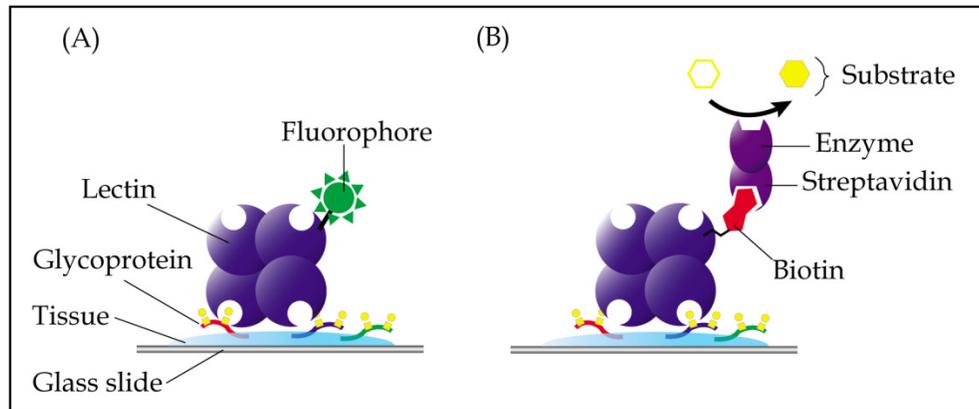

### 334 **Lectin histochemistry**

335 Like immunohistochemistry, lectin histochemistry is a microscopy-based technique for  
336 visualization of cellular components of tissues except that it uses lectin instead of antibodies.  
337 Utilization of labelled lectins in the tissue staining procedure limits the technique to detection  
338 of only glycan-conjugated components, as well as those whose glycan moieties are being  
339 recognized specifically by the individual lectins. Unlike immunohistochemistry which  
340 detects presence of specific antigens based on the specificities of antibodies used, lectin  
341 histochemistry provides information concerning glycosylation processes within a tissue

342 sample as well as their intracellular locations. This information can be very useful in the  
343 characterization and/or detection of diseases.

344 In lectin histochemistry, labelling can be performed directly or indirectly (*Roth, 2011*).  
345 In the direct labelled method, which is generally less sensitive than the direct method, lectins  
346 are directly linked to fluorophores, enzymes, colloidal gold or ferritin, depending on the  
347 microscopy involved (*Figure 3*, panel A). On the other hand, the indirect method involves  
348 conjugation of lectins with biotin or digoxigenin, which may be detected using enzyme  
349 linked-streptavidin or -anti-digoxigenin, respectively (*Figure 3*, panel B). Apparently, not all  
350 chemicals can be used in the fixation and embedding of tissues in lectin histochemistry. For  
351 example, the use of formaldehyde in fixation of tissue specimens is known to cause reduced  
352 sensitivity of the *Griffonia simplicifolia* agglutinin, whilst ethanol-acetic acid fixation  
353 improved its binding (*Kuhlmann and Peschke, 1984*). Paraffin, which causes denaturation of  
354 proteins, is also known to result in attenuated binding of lectins due to sequestration of  
355 carbohydrates in the glycoproteins that are denatured. However, this can be largely reversed  
356 by removal of tissue-embedded paraffin using xylene or by trypsinization, which breaks the  
357 protein cross-links and allows the lectins to bind more efficiently (*Brooks and Hall, 2012*).

358

359

360 **Figure 3 Common techniques in lectin histochemistry.** Comparative staining of cancer  
 361 versus normal tissues may highlight aberrant glycosylation of glycoproteins. (A) In the direct  
 362 method, glycoproteins are detected in tissue specimens using a lectin that is covalently  
 363 linked to fluorophores, enzymes, colloidal gold or ferritin. (B) The indirect labelled method, which  
 364 is generally more sensitive, involves use of a lectin that is conjugated with a hapten, such as  
 365 biotin or digoxigenin, which are then recognized using enzyme linked-streptavidin or -anti-  
 366 digoxigenin, respectively.

367

368 Lectin histochemistry has been extensively used in the study of glycosylation changes in  
 369 cancer tissues. Two lectins have been found useful in distinguishing the different  
 370 histological grades of mucoepidermoid carcinoma, the most common type of salivary gland  
 371 cancer (*Sobral et al., 2010*). Whilst ConA was demonstrated to be able to stain all grades of  
 372 mucoepidermoid carcinoma tissues, staining with UEA-I lectin showed direct correlation of  
 373 malignancy with the intensity of staining. Another example is cholangiocarcinoma that is  
 374 attributed to the river fluke infection that commonly occurs in Thailand. In the study of the  
 375 parasite-induced cancer, *Indramanee et al. (2012)* have used multiple lectins to demonstrate  
 376 aberrant glycosylation of glycoconjugates in paraffin-embedded liver tissues of patients with  
 377 primary cholangiocarcinoma. Unique lectin staining patterns derived from the cancer

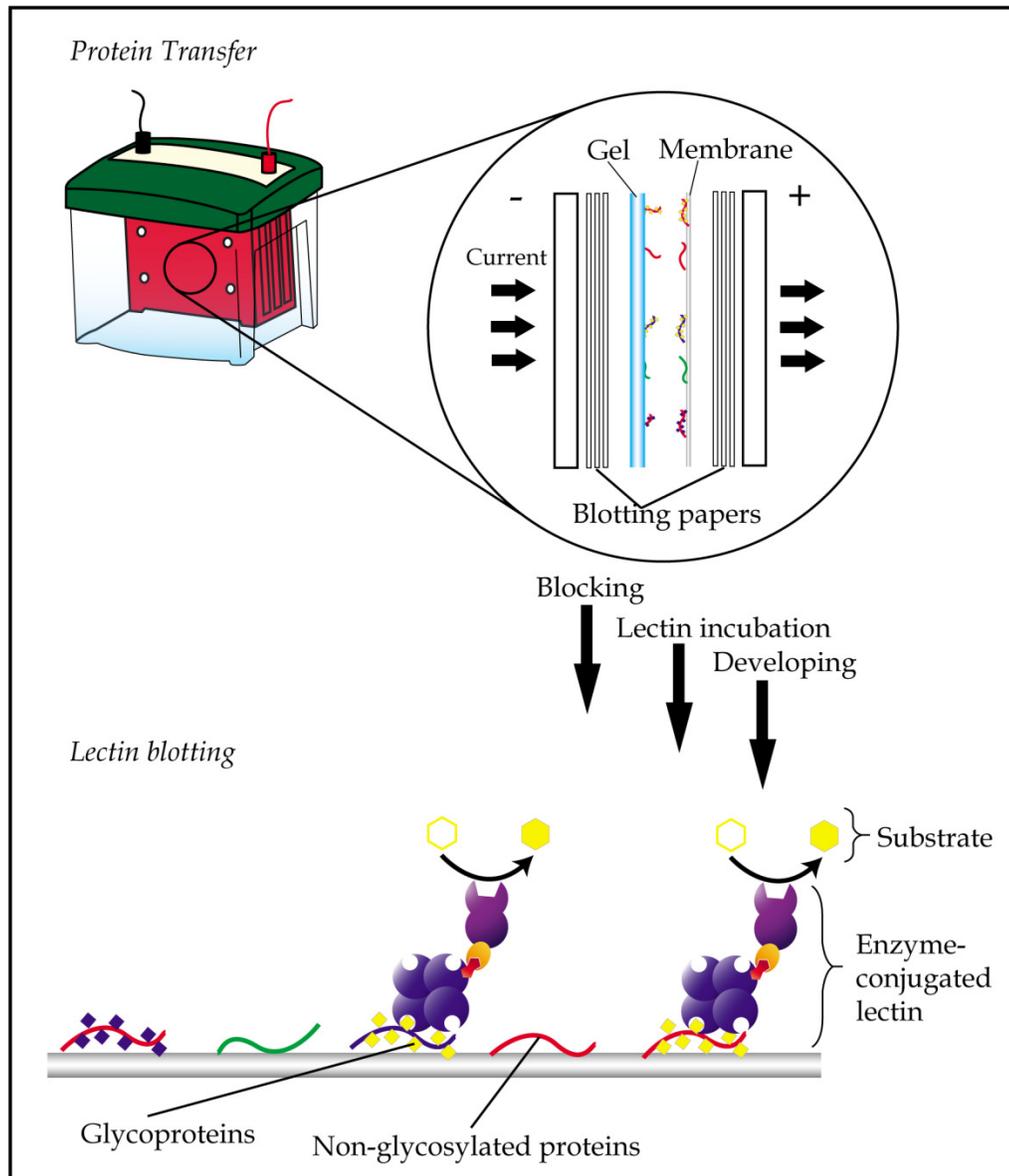

378 patients, relative to non-tumorous tissues, can be utilized as early stage markers for the bile  
379 duct cancer. Similarly, SNA has been proposed for use as a prognostic probe for invasive  
380 ductal carcinoma based on the different staining patterns that were generated compared to  
381 tissue sections of patients with stage 0 breast cancer, ductal carcinoma in situ (*Dos-Santos et*  
382 *al., 2014*). In another histochemical study, eight different lectins have been used to identify  
383 specific carbohydrates that may contribute to the progression of colorectal cancer  
384 (*Hagerbaumer et al., 2015*). The results showed changes in the binding patterns of five of  
385 the lectins during advancement of metastasis from adenoma to colorectal carcinoma.

386

### 387 **Lectin blotting**

388 Lectin blotting is an extension of western blotting that uses lectin instead of antibody to  
389 detect glycoconjugates (*Shan et al., 2001*). As in western blotting, samples are similarly  
390 resolved using polyacrylamide gel electrophoresis and transferred onto a polyvinylidene  
391 fluoride (PVDF) or nitrocellulose membrane but detected using glycan-specific lectin probes  
392 (*Figure 4*). Like histochemistry, visualization of the lectin complex is enabled via the use of  
393 conjugates such as enzymes, fluorescent dyes, biotin, digoxigenin, colloidal gold and  
394 radioactive isotopes. In lectin blotting, the concentrations of lectins used must be at optimal  
395 levels to reduce false-positive binding. Although a powerful tool, this technique is however  
396 not quite suitable for routine diagnostics.

397

398

399 **Figure 4** General workflow of lectin blotting. The method initially involves transferring of  
 400 proteins that are resolved by gel electrophoresis onto a PVDF or nitrocellulose membrane.  
 401 This is then followed by subjecting the membrane to washing, blocking and incubation with  
 402 lectins that are conjugated to an enzyme, a fluorescent dye, biotin, digoxigenin, colloidal gold  
 403 or radioactive isotopes. Comparative blotting of bodily fluids of cancer patients versus those  
 404 from cancer negative subjects may highlight presence of aberrantly glycosylated and/or  
 405 expressed glycoproteins.

406

407 In the past, lectin blotting studies have been especially useful in characterization of  
408 structures of glycans (*Akama and Fukuda, 2006*), detection and quantification of *N*- and *O*-  
409 glycosylated proteins (*Roth et al., 2012*) and detection of altered glycosylation following an  
410 abnormality in glycosylation pathways due to disease processes (*Kitamura et al., 2003*). In  
411 cancer biomarker studies, lectin blotting is often used for comprehensive profiling of  
412 glycosylated proteins in biofluids. For example, the CGB lectin has been extensively used to  
413 demonstrate altered abundances of various *O*-glycosylated proteins in serum and/or urine  
414 samples of cancer patients that were resolved by 2-DE and transferred onto nitrocellulose  
415 membrane. Cancers that have been investigated using the method include endometrial  
416 cancer, cervical cancer (*Abdul-Rahman et al., 2007*), breast cancer, nasopharyngeal  
417 carcinoma, bone cancer (*Mohamed et al., 2008*), ovarian cancer (*Mu et al., 2012*) and  
418 prostate cancer (*Jayapalan et al., 2012; Jayapalan et al., 2013*). Similar lectin blotting  
419 studies have also been applied on cell lines. Examples are the use of *Pinellia pedatisecta*  
420 agglutinin-based lectin blotting analysis to generate unique glycosylation fingerprints for  
421 leukemia and solid tumor cell lines (*Li et al., 2014*), and the utilization of ConA and CGB  
422 lectin to demonstrate altered released of *N*- and *O*-glycosylated proteins from murine 4T1  
423 mammary carcinoma cell line (*Phang et al., 2016*).

424 Another use of lectin blotting is as a means of validation of tumor-specific glycosylation.  
425 Based on earlier results that showed elevated levels of mRNA of specific  
426 glycosyltransferases in endometroid ovarian cancer tissue relative to normal ovary, *Abbott et*  
427 *al. (2010)* have selected three different lectins (*Phaseolus vulgaris* erythroagglutinin, *Aleuria*  
428 *aurantia* lectin and *Datura stramonium* lectin) with distinctive affinities for the respective  
429 products of the enzymes to validate glycosylation changes of glycoproteins that are expressed

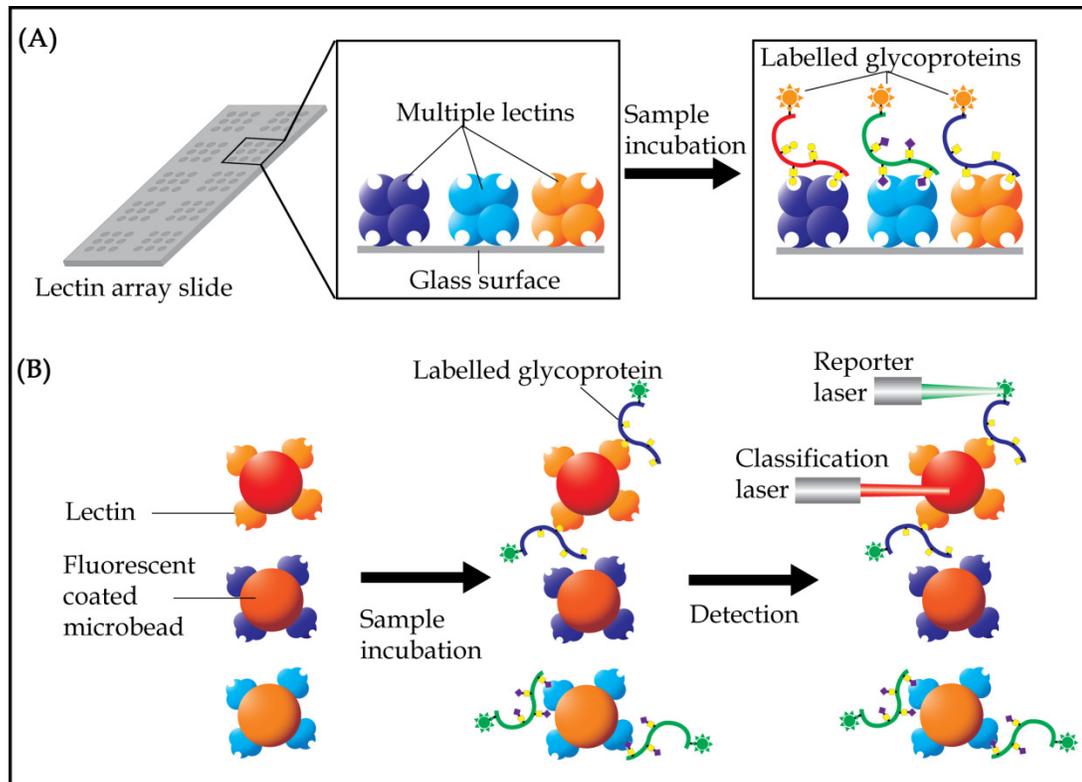

430 in the ovarian cancer tissues. By extracting intact glycoproteins from the ovarian tissues  
431 before isolating the lectin-reactive proteins, the researchers were able to identify a total of 47  
432 potential tumor-specific lectin-reactive markers. In another study, *Qiu et al. (2008)*, using  
433 biotinylated AAL and SNA lectin-blot detection method, were able to validate the  
434 differential *N*-linked glycan patterns that are related to the levels of sialylation and  
435 fucosylation of complement C3 in colorectal cancer patients, compared to those with  
436 adenoma and normal subjects. Similarly, *Park et al., (2012)* have validated earlier findings  
437 of aberration of fucose residues in haptoglobin  $\beta$  chain that is associated with progression of  
438 colon cancer by generating comparable results using *Lotus tetragonolobus* and *Aspergillus*  
439 *oryzae* lectins as detection probes in lectin blotting experiments.

440

#### 441 **Lectin array**

442 Lectin array is a technique that was developed for rapid and sensitive analysis of glycans in a  
443 high-throughput manner. The technique uses multiple lectins, which are mostly plant-  
444 derived, that are immobilized onto a solid support at a high spatial density to detect different  
445 carbohydrate content of glycoproteins or glycolipids in a single sample (*Hu and Wong, 2009*;  
446 *Hirabayashi et al., 2011*). Display of the lectins in an array format enables observation of  
447 the distinct binding interactions simultaneously, which then provides a unique method for  
448 rapid characterization of carbohydrates on glycoconjugates (**Figure 5**, panel A). A glass slide  
449 is the most common material used as solid support for the array application. Lectins are  
450 coated on the glass surface either by covalent interaction or physical adsorption. Glass slides  
451 are usually pre-treated with chemical derivatives such as *N*-hydroxy succinimidyl esters (*Hsu*  
452 *and Mahal, 2006*), epoxides (*Kuno et al., 2005*), biotin, streptavidin (*Angeloni et al., 2005*),

453 and 3D hydrogels (*Charles et al., 2004*). Each droplet of lectin is printed onto the glass slide  
 454 and arranged according to a specific grid map using an array printer. The printed slide is  
 455 held in place by a multi-well gasket, which allows samples to be loaded into each well.  
 456

457

458 **Figure 5 Basic concept of lectin array technology.** (A) Multiple lectins are printed onto a  
 459 slide, which is organized in a grid, single lectin per spot, format. Samples, which are usually  
 460 pre-labelled with either fluorophore or chromophore, are then allowed to interact with the  
 461 lectins. Lectin spots, which contain the labelled glycoproteins, will illuminate under an  
 462 appropriate scanner. (B) In lectin bead array analysis, different fluorescent colored beads,  
 463 each corresponding to a single lectin, are often used. The conjugated beads are then allowed  
 464 to interact with samples and the unbound materials being washed out. The beads are then  
 465 passed through a detector with two laser sources, with the classification laser identifying the  
 466 specific beads, whilst the reporter laser quantifying presence of the labelled samples.

467

468 By using an array of 45 different lectins to determine predictive biomarkers of colorectal  
469 cancer, *Nakajima et al. (2015)* were able to identify 12 lectins that showed increase binding,  
470 whilst 11 more lectins demonstrated low binding of glycoproteins in the colorectal cancer  
471 tissues compared to normal epithelia. Amongst the lectins, *Agaricus bisporus* lectin which  
472 was selected for further validation by the researchers, showed strong potential to be used as a  
473 new predictive biomarker for distant recurrence of curatively resected colorectal cancer. A  
474 similar approach performed on tissue extracts of gastric cancer demonstrated high  
475 interactions of 13 lectins with tissue glycoproteins, whilst 11 others showed low interaction  
476 (*Futsukaichi et al., 2015*). In both these studies, the altered interaction of lectins only  
477 reflected the general presence of glycoproteins that were differently glycosylated without  
478 providing any information on the precise glycoproteins that are affected.

479 In an earlier study, *Wu et al. (2012)* have used lectin array to screen for altered  
480 fucosylated proteins in serum samples of patients with ovarian cancer. Based on the results,  
481 the researchers then immobilized the lectins that showed differential interactions and used it  
482 as affinity chromatography to isolate serum glycoproteins with aberrant glycan structures and  
483 determine their protein identities. This strategy has led to the identification of four serum  
484 glycoproteins with altered fucose residues. Recently, a different lectin array strategy was  
485 also developed to serve as an analytical technique for determination of differences in  
486 glycosylation of proteins that are isolated from serum samples (*Sunderic et al., 2016*). In this  
487 study, the glycan content of serum alpha-2-macroglobulin, which was isolated from serum  
488 samples of patients with colorectal cancer, was studied using the lectin array. From a set of  
489 14 fluorescent labelled lectins that were used in the analysis, statistically significant

490 differences between two groups of patients with colorectal cancer and cancer negative  
491 individuals were found for five of the lectins. When taken together, the results generally  
492 showed that the alpha-2-macroglobulin of patients with colorectal cancer have higher content  
493 of  $\alpha$ 2,6 sialic acid, GlcNAc and mannose residues, and tri-/tetraantennary complex type high-  
494 mannose *N*-glycans.

495 Since its inception, the technology of lectin array has been through several modifications  
496 to improve detectability of glycoproteins in biological samples. The array may involve prior  
497 pre-capturing of a glycoprotein of interest using antibody, and the subsequent detection of  
498 glycans using pre-labelled lectins (*Kuno et al., 2011; Li et al., 2011*). This approach allows  
499 detection of the total glycan content of a specific glycoprotein and also reduces the need for  
500 prior glycoprotein purification. Lectin array is not limited to glass slide as its solid support.  
501 *Wang et al. (2014)* have used fluorescent dyes coated microbeads, which allows multiplex  
502 detection in a single reaction vessel that greatly improves detection sensitivity compared to  
503 the standard lectin arrays. More recently, an alternative approach which involves printing of  
504 purified samples onto a chip surface has also been reported (*Sunderic et al., 2016*).

505 Lectin array analysis can also be performed on magnetic beads (*Figure 5*, panel B).  
506 Known as lectin magnetic bead array, the technique was first introduced as a robust and high-  
507 throughput pipeline for glycoproteomics-biomarker discovery in 2010 (*Loo et al., 2010*).  
508 The method is based on use of multiple lectins that are conjugated to magnetic beads to  
509 isolate glycan specific proteins. These lectin-conjugated beads are incubated with protein  
510 samples, washed and the bound glycoproteins are then eluted in appropriate buffers for  
511 subsequent proteomics analysis. By coupling a mass spectrometer to the one-step  
512 glycoprotein separation and isolation procedure, profiling of glycan-specific proteins may be

513 achieved without much loss of proteins. This increases the probability of identification of  
514 proteins of lower abundances that have biomarker potentials. Nevertheless, a few  
515 methodological concerns need to be carefully considered when using the lectin bead array.  
516 These include surface functionality and diameter of the beads, conditions of buffers and  
517 duration of trypsin digestion protocols for optimal isolation of lectin-binding proteins. In this  
518 technique, understanding of the specificities of lectins is also imperative as most glycosylated  
519 proteins are expected to have multiple glycosylation sites for interaction with the lectins.

520 Using a panel of 20 lectins in a magnetic bead array that was coupled to a tandem mass  
521 spectrometer, *Shah et al. (2015)* have demonstrated unique lectin-glycoprotein interactions in  
522 serum samples that may be used to distinguish three groups of subjects comprising healthy  
523 volunteers, patients with Barrett's esophagus and patients with esophageal adenocarcinoma.  
524 Their results demonstrated the possibility of using apolipoprotein B-100 to distinguish  
525 healthy volunteers from patients with Barrett's esophagus. The use of *Narcissus*  
526 *pseudonarcissus* lectin in the assay was able to differentiate differently glycosylated  
527 apolipoprotein B-100 in the two groups of subjects. On the other hand, patients with  
528 Barrett's esophagus were markedly distinguishable from those with esophageal  
529 adenocarcinoma via differences in the glycosylation of AAL-reactive complement  
530 component C9, whilst PHA-reactive gelsolin was shown to have potential in differentiating  
531 healthy subjects from patients with esophageal adenocarcinoma.

532

533 **Challenges and future directions**

534 Development and progression of cancer are associated with altered glycosylation and  
 535 aberrantly expressed glycoproteins. Hence, the use of lectin-based assays and strategies that  
 536 are discussed in this review article, together with the emergence of proteomics technology,  
 537 has led to identification of hundreds of putative glycopeptide biomarkers that can be utilized  
 538 in clinical practice. A summary on the advantages and disadvantages of these lectin-based  
 539 techniques is shown in [Table 4](#). However, the translation of biomarkers from discovery to  
 540 clinically approved tests is still much to be desired. This is mainly attributed to the lack of  
 541 follow-up characterization and validation investigations of the potential biomarkers, which is  
 542 an absolute requirement to ensure that the discovery phase experiments are not flawed and  
 543 that detection of the biomarkers is reproducible, specific and sensitive ([Diamandis, 2012](#);  
 544 [Drucker and Krapfenbauer, 2013](#)). A potential glycopeptide biomarker has to be validated  
 545 using hundreds of specimens to become clinically approved tests. Hence, this is certainly not  
 546 possible in cases of rare cancers.

547

548 **Table 4** Advantages and disadvantages of lectin-based techniques in cancer biomarker  
 549 discovery research.

Techniques	Advantages	Disadvantages
<b>Lectin affinity chromatography</b>	<ul style="list-style-type: none"> <li>• Does not require purified glycoproteins or glycans</li> <li>• Detailed analysis of glycan</li> <li>• High affinity</li> </ul>	<ul style="list-style-type: none"> <li>• Requires large amounts of samples</li> <li>• Time-consuming</li> <li>• Allows for individual samples only</li> <li>• Co-elution of other proteins</li> </ul>
<b>Enzyme-linked lectin assay (ELLA)</b>	<ul style="list-style-type: none"> <li>• Relatively high-throughput</li> <li>• Quantitative</li> <li>• Easy to perform</li> <li>• Very cost effective</li> <li>• Requires minute amounts of samples</li> <li>• In case of hybrid ELLA, prior</li> </ul>	<ul style="list-style-type: none"> <li>• Glycoproteins that are detected may not be identifiable unless it is coupled with further proteomics analysis or antibody detection.</li> <li>• In case of hybrid ELLA, non-specific direct interaction of</li> </ul>

	purification of a glycoprotein is not required	lectin to antibodies may occur
<b>Lectin histochemistry</b>	<ul style="list-style-type: none"> <li>•Simple</li> <li>•Rapid</li> <li>•Allows lectin multiplexing with the use of fluorescent tags</li> </ul>	<ul style="list-style-type: none"> <li>•Require purified glycans or glycoproteins as standard</li> <li>•Requires skills for tissue preparation</li> <li>•Requires use of multiple lectins/antibodies to provide further confirmation</li> <li>•Certain fixatives or components may reduce sensitivity</li> </ul>
<b>Lectin blotting</b>	<ul style="list-style-type: none"> <li>•Visualization of small amounts of proteins</li> <li>•Easy to detect</li> <li>•High specificity and sensitivity</li> <li>•Reliable and reproducible</li> <li>•Convenient method of screening of complex protein samples</li> </ul>	<ul style="list-style-type: none"> <li>•Choice of membrane may affect protein binding capacity and chemical stability</li> </ul>
<b>Lectin array</b>	<ul style="list-style-type: none"> <li>•Does not require purified glycoproteins or glycans</li> <li>•Rapid</li> <li>•Highly sensitive</li> <li>•High-throughput</li> <li>•Allows multiplexing</li> <li>•Requires small amounts of samples</li> </ul>	<ul style="list-style-type: none"> <li>•Requires extensive optimization</li> <li>•Possible non-specific interaction</li> </ul>

In some cases, validation may not be successful with the use of a single cancer biomarker in a single assay. One solution is to explore the simultaneously use of several different biomarkers for development of a highly specific and sensitive assay (*Pang et al., 2010*). Hence, there is an urgent need to consolidate data on availability of all putative glycopeptide biomarkers that have been unmasked from the discovery phase studies for every different application in every cancer. In addition, new high throughput assays for simultaneous detection of multiple biomarkers are also required. The recent technological advances in chip-based protein microarray technology (*Sauer, 2017*) may provide with the solution, and

560 therefore ought to be explored for simultaneous validation analysis of the different  
561 biomarkers in a single experiment.

562 In many other cases, identification of the potential glycopeptide biomarkers using lectin-  
563 based strategies may involve complex separation techniques such as 2-DE, which is  
564 laborious and expensive for large scale validation studies. 2-DE comes with the advantage of  
565 knowing the actual experimental molecular weight of a glycopeptide biomarker, which is not  
566 possibly attained from liquid-based separation methods. This is important as many tumor  
567 associated glycopeptides are known to be truncated products of native glycoproteins (*Pinho  
568 and Reis, 2015*). For these potential biomarkers, validation experiments would need to  
569 involve a different indirect high-throughput technique using both lectin as well as an  
570 antibody that is capable of differentiating truncated glycopeptides from their native  
571 glycoprotein structures. However, such antibodies are usually not available commercially,  
572 and generating them is time consuming, costly and involves substantial laboratory work.
