*Galianthe* (Rubiaceae) is a neotropical genus comprising 50 species divided into two subgenera, *Galianthe* subgen. *Galianthe*, with 39 species and *Galianthe* subgen. *Ebelia*, with 11 species. The diagnostic features of the genus are: usually erect habit with xylopodium, distylous flowers arranged in lax thyrsoid inflorescences, bifid stigmas, 2-carpellate and longitudinally dehiscent fruits, with dehiscent valves or indehiscent mericarps, plump seeds or complanate with a wing-like strophiole, and pollen with double reticulum, rarely with a simple reticulum. This study focused on two species that were originally described under *Diodia* due to the occurrence of fruits indehiscent mericarps: *Diodia palustris* and *D. spicata*. In the present study, classical taxonomy is combined with molecular analyses. As a result, we propose that both *Diodia* species belong to *Galianthe* subgen. *Ebelia*. The molecular position within *Galianthe*, based on ITS and ETS sequences, has been supported by the following morphological characters: thyrsoid, spiciform or cymoidal inflorescences, bifid stigmas, pollen grains with a double reticulum, and indehiscent mericarps. However, both species, unlike the remainder of the genus *Galianthe*, have homostylous flowers, so the presence of this type of flower significantly modifies the generic concept. In this framework, a third homostylous species, *Galianthe vasquezii*, from the Andean region is also described. Until now, this species remained cryptic under specimens of *Galianthe palustris*. It differs however from the latter by having longer calyx lobes, the presence of dispersed trichomes inside the corolla lobes (vs. glabrous), fruits that are acropetally dehiscent (vs. basipetally dehiscent), and its Andean geographical distribution (vs. Paranaense). Additionally, a lectotype has been chosen for *Diodia palustris*, *Borreria pterophora* has been placed under synonymy of *Galianthe palustris*, and *Galianthe boliviana* is reported for the first time from Peru. A key of all

*Galianthe* species with indehiscent mericarps is also provided.

**11 ABSTRACT**

**12** *Galianthe* (Rubiaceae) is a neotropical genus comprising 50 species divided into two subgenera,  
**13** *Galianthe* subgen. *Galianthe*, with 39 species and *Galianthe* subgen. *Ebelia*, with 11 species. The  
**14** diagnostic features of the genus are: usually erect habit with xylopodium, distylous flowers  
**15** arranged in lax thyrsoid inflorescences, bifid stigmas, 2-carpellate and longitudinally dehiscent  
**16** fruits, with dehiscent valves or indehiscent mericarps, plump seeds or complanate with a wing-  
**17** like strophiole, and pollen with double reticulum, rarely with a simple reticulum. This study  
**18** focused on two species that were originally described under *Diodia* due to the occurrence of  
**19** fruits indehiscent mericarps: *Diodia palustris* and *D. spicata*. In the present study, classical  
**20** taxonomy is combined with molecular analyses. As a result, we propose that both *Diodia* species  
**21** belong to *Galianthe* subgen. *Ebelia*. The molecular position within *Galianthe*, based on ITS and  
**22** ETS sequences, has been supported by the following morphological characters: thyrsoid,  
**23** spiciform or cymoidal inflorescences, bifid stigmas, pollen grains with a double reticulum, and  
**24** indehiscent mericarps. However, both species, unlike the remainder of the genus *Galianthe*, have  
**25** homostylous flowers, so the presence of this type of flower significantly modifies the generic  
**26** concept. In this framework, a third homostylous species, *Galianthe vasquezii*, from the Andean  
**27** region is also described. Until now, this species remained cryptic under specimens of *Galianthe*  
**28** *palustris*. It differs however from the latter by having longer calyx lobes, the presence of  
**29** dispersed trichomes inside the corolla lobes (vs. glabrous), fruits that are acropetally dehiscent  
**30** (vs. basipetally dehiscent), and its Andean geographical distribution (vs. Paranaense).  
**31** Additionally, a lectotype has been chosen for *Diodia palustris*, *Borreria pterophora* has been

placed under synonymy of *Galianthe palustris*, and *Galianthe boliviana* is reported for the first time from Peru. A key of all *Galianthe* species with indehiscent mericarps is also provided.

## INTRODUCTION

*Galianthe* Griseb. is a neotropical genus belonging to tribe Spermacoceae (Groeninckx et al., 2009a). The genus was revised by Cabral (2002) and divided into two subgenera (Cabral & Bacigalupo, 1997): *Galianthe* subgen. *Galianthe*, from South America with 39 species, and *Galianthe* subgen. *Ebelia* (Rchb.) E.L. Cabral & Bacigalupo, with 11 Mesoamerican and South American species. Historically, *Galianthe* was associated with *Diodia* L., which has been described based on only *D. virginiana* L. The type species has a palustrine habit, pauciflorous axillary inflorescences, filiform corolla tube, bifid style with two long filiform stigmatic lobes, and indehiscent fruits. Later, others authors (i.e. Swartz 1788; Walter 1788, Candolle 1830, Small 1913) added other species into this genus with diverse kinds of habits and inflorescences, different floral morphology (e.g. distyly or homostyly, infundibuliform or campanulate corollas, bifid or bilobate stigma), and 2-carpellate schizocarpic fruits, being currently comprised by ca. 180 names (called *Diodia s. lat.*). Later, Bacigalupo & Cabral (1999) revised the genus *Diodia* and maintained only five species that were morphologically similar to the type species *D. virginiana* L. (description as above, and constituting *Diodia s. str.*). Species that did not match with these diagnostic features, were transferred to other genera as follows: eight species to *Borreria* subgen. *Dasycephala* (DC.) Bacigalupo & E.L. Cabral (Bacigalupo & Cabral, 1996), 12 species to *Hexasepalum* Bartl. ex DC. (Kirkbride 2014; Kirkbride & Delprete, 2015; Cabaña Fader et al., 2016), and 4 species to *Galianthe* subgen. *Ebelia* (Cabral & Bacigalupo, 1997). The four *Galianthe* species are distylous, *Diodia bogotensis* (Kunth) Cham. & Schltdl. [= *Galianthe bogotensis* (Kunth) E.L. Cabral & Bacigalupo]; *D. brasiliensis* Spreng. [= *G. brasiliensis* (Spreng.) E.L. Cabral & Bacigalupo]; *D. cymosa* Cham. [= *G. cymosa* (Cham.) E.L. Cabral & Bacigalupo], and *D. hispidula* A. Rich. ex DC. [= *G. hispidula* (A. Rich. ex DC.) E.L. Cabral & Bacigalupo]. The remaining species with an uncertain position (ca. 150 names) are currently under revision (Cabaña Fader com. pers.). In this sense, Bacigalupo and Cabral (1996, 1998) transferred these species to *Borreria* subgen. *Dasycephala* because of their homostylous flowers and indehiscent mericarps, while Delprete et al. (2005) and Delprete (2007), alluding to a broad concept, transferred the two species to *Spermacoce* mainly based on fruit characters. Dessein (2003) informally proposed to consider *Diodia spicata* as part of *Galianthe* based on molecular data (ITS intron), palynological data (double reticulum), and fruit morphology. The aim of this

work is to confirm the taxonomic position of *D. palustris* and *D. spicata* based on morphological and molecular data, and perform their formal combination in *Galianthe*. In addition, a third homostylous species (*Galianthe vasquezii* R.M Salas & J. Florentín) is described and illustrated based on specimens from Colombia and Peru (previously identified as *D. palustris*). Additionally, a lectotype has been chosen for *Diodia palustris* whereas *Borreria pterophora* has been placed under synonymy of *Galianthe palustris*. Moreover *Galianthe boliviana* E.L. Cabral is for the first time recorded in Peru. Finally, we provided a distribution map for the species investigated in this study, as well as a dichotomous key for all taxa with indehiscent mericarps.

## MATERIALS AND METHODS

### Morphological Study

This study is based on classical taxonomy techniques. Collections deposited at the BA, BHCB, CEPEC, CTES, ESA, FUEL, FPS, FURB, HAS, HOXA, HUT, IAC, IAN, IFFSC, IPA, K, LIL, MBM, MO, NY, P, PR, SI, SP, UB, UFRN, USB, US, USM and UEC herbaria were analysed. Furthermore, the databases of the ‘Catálogo de plantas e fungos do Brazil’ and ‘Missouri Botanical Garden’ were examined. In order to carry out scanning electron microscope (SEM) analyses, flowers were dehydrated using a graded series of ethanol solutions and afterwards critically point dried and sputter-coated with gold-palladium. SEM images were obtained with a JEOL 5800 LV scanning electron microscope. Pollen grains were acetolyzed according to Erdtman (1966) and mounted in glycerine jelly for analysis by light microscopy (LM). Conventional parameters (P = polar axis, E = equatorial axis) of at least 20 grains were measured under LM, and the exine was analyzed using SEM. Pollen terminology follows Punt *et al.* (2007). Species distribution maps were generated from distribution data that was present on the herbarium labels for each specimen and subsequently georeferenced using *Google Earth* (2015) and *DIVA-GIS* (2013).

"The electronic version of this article in Portable Document Format (PDF) will represent a published work according to the International Code of Nomenclature for algae, fungi, and plants (ICN), and hence the new names contained in the electronic version are effectively published under that Code from the electronic edition alone. In addition, new names contained in this work which have been issued with identifiers by IPNI will eventually be made available to the Global Names Index. The IPNI LSIDs can be resolved and the associated information viewed through any standard web browser by appending the LSID contained in this publication to the prefix

95 "http://ipni.org/". The online version of this work is archived and available from the following  
96 digital repositories: PeerJ, PubMed Central, and CLOCKSS".

# 97 **Molecular study**

98 In total, 45 species (47 accessions) were included to infer the phylogenetic relationship of *Diodia*  
99 *palustris* and *D. spicata*. The ingroup contains species from the *Borreria*, *Carajasia* R.M. Salas,  
100 E.L. Cabral & Dessein, *Crusea* Cham. & Schltdl., *Diodia*, *Emmeorhiza* Pohl ex Endl., *Ernodea*  
101 Sw., *Galianthe*, *Hexasepalum*, *Mitracarpus* Zucc., *Psyllocarpus* Mart. & Zucc., *Richardia* L.,  
102 *Schwendenera* K. Schum., *Spermacoce*, and *Staelia* Cham. & Schltdl. genera, and *Bouvardia*  
103 *ternifolia* (Cav.) Schltdl. as the outgroup. Leaf samples of these studies were obtained from silica  
104 gel-dried material or herbarium materials. Forty-three species (44 accessions) were previously  
105 used by *Salas et al. (2015)*. Four accessions belonging to *D. palustris* has been added. All studied  
106 species with geographical information, collector, herbarium and GenBank accession numbers are  
107 provided in Appendix.

# 108 **Molecular Protocols**

109 Total genomic DNA was isolated from silica-dried leaf material using a modified CTAB protocol  
110 (*Doyle and Doyle 1987*). Nuclear ribosomal ETS and ITS fragments were amplified following  
111 *Baldwin and Markos (1998)* and *Negrón-Ortiz and Watson (2002)*, and *White et al. (1990)*,  
112 respectively. PCR reactions for both gene markers investigated in this study consisted of 2 min  
113 initial denaturation at 94 °C and 30 cycles of 30 s denaturation at 94 °C, 30 s primer annealing at  
114 primer specific temperature and 1 min extension at 72 °C. Primer annealing for ETS and ITS  
115 were at 47°C and 48°C respectively. Amplification reactions were carried out on a GeneAmp  
116 PCR system 9700 (Applied Biosystems). Purified amplification products were sent to Macrogen,  
117 Inc. (Seoul, South Korea) for sequencing. Sequences obtained in this study were deposited at  
118 GenBank [*Diodia palustris*, *Verdi et al. 1905*, ETS (MF166824), ITS (MF166826); *Miguel et al.*  
119 *19*, ETS (MF166825), ITS (MF166827)].

# 120 **Phylogenetic analyses**

121 Contiguous sequences were assembled using Geneious v7.0.6 (Biomatters, New Zealand).  
122 Automatic alignments were carried out with MAFFT (*Katoh et al., 2002*) Subsequent manual  
123 finetuning of the aligned dataset was done in Geneious v7.0.6. Congruency between the different  
124 datasets was inferred using different methods. First, a series of incongruence length difference

tests (ILD; Farris *et al.*, 1995) were carried out with PAUP\* v.4. 0b10 (Swofford, 2003) using the following parameters: simple taxon addition, TBR branch swapping and heuristic searches of 1000 repartitions of the data. Despite the well-known sensitivity of the ILD test (Barker and Lutzoni, 2002), the results of this test were compared in light of the resolution and support values of the obtained nuclear and nuclear ribosomal topologies. As a result, possible conflict between data matrices was visually inspected, searching for conflicting relationships within each topology that are strongly supported (hard vs. soft incongruence; Johnson and Soltis, 1998). Model selection for the Bayesian inference analysis was conducted with ModelTest 3.06 (Posada & Crandall 1998) under the Akaike Information Criterion (AIC). The GTR+G model was selected for both ITS and ETS. Bayesian analyses of the concatenated dataset were carried out with MrBayes 3.1 (Huelsenbeck & Ronquist 2001, Ronquist & Huelsenbeck 2003). Four chains (one cold, three heated), initiated from a random starting tree were run simultaneously for 10 million generations. Every 1000 generations, a tree was sampled from the chain for a total of 10,000 trees. Due to the burn-in, 50% of the sample points were discarded. Convergence of the chains was examined with TRACER 1.4 (Rambaut & Drummond 2007). This resulted in an effective sampling size (ESS) parameter exceeding 100, which assumes a sufficient sampling and acceptable mixing.

## RESULTS

### Phylogenetic results

The ingroup contains 14 genera represented by 45 species of the *Spermacoce* clade. Of these, *Diodia spicata* and *D. palustris* are analysed for the first time in this context. ITS and ETS datasets were analysed both separately and combined. Because topology of each gene marker is very similar, we only present the results of the combined analysis (Fig. 1). Current results indicate that most clades coincide with most currently accepted genera (e.g. *Crusea*, *Emmeorrhiza*, *Ernodea*, *Diodia s.s.* (sensu Bacigalupo & Cabral, 1999), *Mitracarpus*, *Psyllocarpus*, *Richardia* and *Staelia*). *Spermacoce*, *Borreria* and *Hexasepalum* however, appear unresolved or as polyphyletic genera being present in several different parts of the tree. In regard of the species studied, we found that *G. spicata* and *G. palustris* fall intermingled among the *Galianthe* species. The *Galianthe* clade, including both former *Diodia* species, is strongly supported (Bayesian Posterior Probability (BBP): 100). The genus is divided into two strongly supported subclades, one subclade consists of *G. grandifolia* E.L. Cabral, *G. eupatorioides*

(Cham. & Schltdl.) E.L. Cabral, and *G. peruviana* (Pers.) E.L. Cabral (BBP: 100), all from *G.* subgen. *Galianthe*. The other subclade (BBP: 99) comprises *G. spicata*, *G. palustris*, and *G. brasiliensis* (type species of *Galianthe* subgen. *Ebelia*). The clade of *Galianthe* and *Carajasia* is only moderately supported (BBP: 79). The genera *Galianthe* and *Carajasia* share the occurrence of pollen grains with a double reticulum, mostly associated with the distyly and bifid stigma. The *Galianthe*-*Carajasia* clade forms an unsupported trichotomy with *Schwendenera* (also distylous) and the remaining genera of the *Spermacoce* clade (all homostylous species never associated to double reticulum pollen grains). Interestingly, all clades that coincide with generic concepts are strongly supported [e.g. *Psyllocarpus* (BBP:99), *Spermacoce* s.s. (BBP:100), *Richardia* (BBP:100), *Borreria* s.s. (BBP:100), *Mitracarpus* (BBP:97), *Hexasepalum* s.s., *Staelia* (BBP:99), *Diodia* s.s. (BBP:100), *Borreria latifolia* group (BBP:100), and *Crusea* (BBP:100)]. The species assigned to *Borreria* (sensu Bacigalupo & Cabral, 1996) are divided into two clades that are intermingled with other morphologically well-defined genera. One of these clades, further referred to as the *Borreria latifolia* group, comprises *Borreria alata*, *B. schumannii*, and *B. latifolia* (BBP:100). The other clade comprises five *Borreria* species from North and South America (*B. capitata*, *B. multibracteata*, *B. tenella*, *B. dasycephala*, and *B. verticillata*), as well as the African *Spermacoce dibrachiata* (BBP: 100). *Spermacoce* is divided into two unrelated branches, of which one clade comprises the type species *S. tenuior*, other American species with similar flower morphology (*S. eryngioides*, *S. prostrata*, *S. incognita*, *S. confusa*, and *S. glabra*, all with stamens and style included), and the Australian *S. breviflora* (support 100). As mentioned above, the other species of *Spermacoce* (*S. dibrachiata*) falls among the species of *Borreria*. *Hexasepalum* species are also divided into two clades, one of them is well supported (BBP: 99) and contain *H. angustifolium* Bart. ex DC. (type species), *H. apiculatum* and *H. teres*. The other, only represented by *H. sarmentosum* appears as sister species of the *Ernodea* (BBP: 100). The genus *Ernodea*, represented by *E. taylori* and *E. littoralis*, constitutes a strongly supported clade (BBP: 100). The results explained above allow us to support the following taxonomic changes.

## TAXONOMIC TREATMENT

### *Description of the new species*

***Galianthe vasquezii*** R. M. Salas & J. Florentín, *sp. nov.* TYPE. PERU: Pasco, Oxapampa, Parque Nacional Yanachaga-Chemillen, Quebrada Yanachaga, 2250 m, 10°24'S, 75°28'W, 14 Jun 2003, R. Vásquez M. 28284 (holotype: HOXA!; isotypes MO!, HUT, USM).

187 **Description**

188 Herb decumbent or prostrate, stems quadrangular, angle strongly alate, with scabridous papillae,  
 189 more densely disposed near nodes. Leaves sessile or pseudopetiolate, pseudopetiole up to 4 mm  
 190 long, blades elliptic or obovate, apex acute, base attenuate,  $12-32 \times 5-17$  mm, plicate-nervose,  
 191 adaxially glabrous or puberulous, abaxially scabridous on nerves, margin scabridous, with 3-5  
 192 secondary nerves; stipular sheath 3.2-5.6 mm long, with 7-9 linear fimbriae, glabrous, fimbriae  
 193 3.5-6.8 mm long. Inflorescences thyrsoid, partial inflorescences subglomeriform, multiflorous.  
 194 Flower pedicellate; pedicel 1-2 mm long; calyx (3-) 4-lobed, hypanthium 1.1-1.3 mm long,  
 195 glabrous or glabrescent, lobes narrowly triangular, 1-1.4 mm long, glabrous, apex acute; corolla  
 196 infundibuliform, 3-lobed, 1.75-2.1 mm long, white; lobes ovate, internally with hairs scattered at  
 197 base, tube internally with some dispersed hairs near its base and externally glabrous, straight;  
 198 stamens subincluded, anther 0.4-0.6 mm long, oblong, filament fixed immediately below  
 199 interlobular sinuses; pollen grains 7-8 zonocolpate, oblate-spheroidal to prolate spheroidal, small,  
 200  $P = 31 \mu\text{m}$ ,  $E = 29 \mu\text{m}$ , colpi long, endoaperture an endocingulum, exine semitectate, reticulate,  
 201 muri nanospinose,  $0.18-0.3 \mu\text{m}$  long; style bifid, 1.5-1.8 mm long, stigmatic branches ca. 0.2 mm  
 202 long, with conspicuous papillae. Fruit a capsule, cordate or deltoid in outline,  $1.8-2 \times 1.6-1.9$   
 203 mm, glabrous, with two indehiscent mericarps which split from the base upwards, each valve  
 204 remains temporary attached in upper half, at maturity caduceus, seed  $1.8-2 \times 0.8-1$  mm, ovoid,  
 205 ventral face longitudinally furrowed, partially covered by the strophiole; exotesta reticulate-  
 206 foveate. Fig. 2, 3

207 **Distribution**—Andes of Peru and Colombia.

208 **Observations**—All specimens of the *G. vasquezii* were previously identified as *Galianthe*  
 209 *palustris*. However, it differs from *G. palustris*, in having calyx lobes 1-1.4 mm long, with acute  
 210 apex (vs. calyx lobes 0.4-0.6 mm long, obtuse), corolla 1.75-2.1 mm long, lobes internally with  
 211 hairs scattered at base, tube internally with some dispersed hairs near its base (vs. corolla 1-1.5  
 212 mm long, internally glabrous), pollen grains with reticulate exine, muri nanospinose (vs. pollen  
 213 grains with bireticulate exine, supracreticulum psilate and incomplete, infrareticulum  
 214 nanospinose), fruit 1.8-2. mm long, deltoid in outline, acropetally dehiscent (vs. fruit 1.1-1.5 mm  
 215 long, oblong or obovate in outline, basipetally dehiscent), and seeds 1.8-2 mm long (vs. seeds 1-  
 216 1.42 mm long).

217 **Ecology**—*Galianthe vasquezii* grows in Montane Forest of Peru and Colombia, which represents  
218 a severely fragmented type of vegetation. It grows between 1800 and 2500 m altitude.

219 **Conservation status**—The extent of occurrence (EOO) was calculated to be 397 km<sup>2</sup> (cell sized 2  
220 km). Following the IUCN criteria (IUCN, 2001), this species should be considered as endangered  
221 [EN B1 ab (ii, iii)], due to the continuing decline in area and quality of its habitat.

222 **Additional Specimens Examined**—COLOMBIA: Antioquia, Monte del Diablo, 21 Jul. 1944,  
223 *Bro. Daniel* 3303 (US); Rio Negro, 16 Dec. 1933, *Bro. Daniel* 165 (US). PERU: Distrito

246 **Description**

247 Herb stoloniferous, sometimes with ascendant stems. Stems quadrangular, angle strongly winged,  
 248 wing with long and slightly recurved fimbriae, or with scabridous and retrorse papillae, especially  
 249 near foliar nodes. Leaves subsessile or pseudopetiolate; pseudopetiole 1-4 mm long; blades  
 250 elliptic or obovate, rarely orbicular, 22-30 mm × 10-18.6 mm, apex obtuse, acute or acuminate,  
 251 base attenuate, plicate-nervose, with 3-4 secondary nerves, adaxially glabrous or scaberulous,  
 252 margin scaberulous, abaxially scabridous only on nerves; stipular sheath 3-4 mm long, basally  
 253 alate, 7-9 fimbriate, fimbriae linear, glabrous, 5-8 mm long. Inflorescences thyrsoïd, partial  
 254 inflorescences congested and multiflorous, sometimes arranged on pleiochasium. Flowers shortly  
 255 pedicellate; pedicel 0.5-1 mm long; calyx 2(-3)-lobed, hypanthium glabrous, lobes triangular,  
 256 apex obtuse, succulent, 0.4-0.6 mm long; corolla 2-3-lobed, infundibuliform, white, 1-1.5 mm  
 257 long, tube internally and externally glabrous, scarcely papillate on apex of the dorsal face of  
 258 lobes; stamens 2-3, anthers 0.2-0.34 mm long, oblong, dorsal surface with a bullate connective,  
 259 immediately above the insertion of the filament; pollen grains 6-7(-8) zonocolporate, oblate-  
 260 spheroidal, small, P= 24 µm, E= 25.3µm, long colpi, endoaperture an endocingulum, exine  
 261 bireticulate, supracreticulum incomplete, muri psilate, infrareticulum complete, muri nanospinose,  
 262 0,15-0,28 µm long; style bifid, 1-1.5 mm long, stigmatic branches 0.2-0.46 mm long, notoriously  
 263 papillate. Fruit a capsule, which separates from the apex downwards into two indehiscent  
 264 mericarps, both mericarps remain basally united to the pedicel, tardily deciduous, oblong or ovate  
 265 in outline, glabrous; seeds 1-1.42 × 0.7-0.8 mm, ovate or obpiriforme in outline, ventral surface  
 266 with a longitudinal furrow covered by a persistent strophiole; exotesta reticulate-foveate. Fig. 3

267 **Distribution**—Brazil (Bahia, Minas Gerais, Paraná, Rio de Janeiro, Rio Grande do Sul, Santa  
 268 Catarina, and São Paulo), and Argentina, Misiones province.

269 **Ecology**—*Galianthe palustris* is a heliophilous plant that inhabits in swampy areas near lotic  
 270 water bodies, especially along main rivers and their tributaries.

271 **Additional Specimens Examined**—ARGENTINA. Misiones: San Pedro, Parque Provincial

**Taxonomic notes**—Until the present, *Borreria pterophora* has been considered as an imperfectly  
known but valid name, which is at present day also registered as an endemism of Rio de Janeiro  
state, Brazil (BFG, 2015), however the examination of the holotype deposited at PR revealed us  
that is a new synonym of *Galianthe palustris*.

### 349 **Description**

Herb or subshrub 80-140 cm alt., erect, stems simple to much branched. Stems quadrangular, fistulose, glabrous, angle weakly alate or without wings, glabrous. Leaves pseudopetiolate, pseudopetiole 0.5-2 mm long, blades elliptic or narrowly elliptic, papery or subcoriaceous when dry, adaxially glabrescent or scabridous, abaxially glabrous, only scabridous on nerves, base acute or cuneate, apex acute or acuminate, 30-110 × 10-33 mm; 5-7 secondary nerves, visible on both faces; stipular sheath 1.5-3 mm long, margin truncate or scarcely triangular, pilose, with 5-7 fimbriae, fimbriae 2-7 mm long, with some antrorse hairs. Inflorescences spiciform, partial inflorescences glomeriform, axillary, (5)10-25 per flowering branch, with 3-20 flowers, bracts foliaceous, decreasing in size towards the apex, sometimes up to the same size than the partial inflorescence. Flowers homostylous, calyx 4-lobed, hypanthium obconic, 0.55-6 mm long, puberulous, lobes 0.2-0.3 mm long, unequal, subtriangular, apex acute, margin ciliate; corolla subtubular, slightly expanded to the apex, 1-1.2 mm long, white or greenish white, sometimes with apex of lobes lilac, glabrescent outside, with a ring of moniliform hairs near insertion of the filaments, tube 0.5-0.7 mm long, lobes ovate, apex acute, internally with some scattered hairs, externally pilose and papillose, especially at the apex, 0.2-0.5 mm long, anthers 0.2-0.25 mm long, oblong, sometimes with a theca visibly smaller than the other, filament 0.15 mm long; pollen grains 7-zonocolpate, prolato-spheroidal, small, P= 30.3 µm, E= 28 µm, colpi long, endoaperture an endocingulum, tectum bireticulate, microreticulate, supracreticulum psilate, infrareticulum with muri nanospinose or psilate; stigma bifid, divided up to the half of its length, with papillae only in the internal face of the stigmatic branches, scarcely exerted. Fruit a capsule, 1.2-1.4 × 1-1.2 mm, longitudinally separated from the pedicel upwards up to median portion of the fruit, both mericarps remain attached to each other at the upper part, mericarps indehiscent, subglobose, ventral face flat, slightly laterally compressed, dorsal face pubescent, hispidulous or

373 glabrescent; seeds  $0.8-1 \times 0.35-0.45$  mm, oblong or ovate in outline, plane-convex, ventral face  
374 with a ample groove, dark brown or nigrescent; exotesta reticulate-foveate, cells polygonal,  
375 almost isodiametric. Fig. 4, 5

376 **Distribution**—Brazil (Amazonas, Roraima, Rondônia, Para, Mato Grosso), Colombia (Chocó),  
377 French Guiana, Panamá, Suriname, and Venezuela (Amazonas y Anzoátegui).

378 **Ecology**—*Galianthe spicata* grows inside or edges of humid forests.

379 **Additional Specimens Examined**—BRAZIL: Amazonas, vicinity of Camp Tucano, Rio Tucano,

412 ***First record from Peru***

413 ***Galianthe boliviana*** E.L. Cabral, *Brittonia* 57(2): 142, f. 1. 2005. TYPE. BOLIVIA: La Paz:  
 414 Inquisivi, Cerro Aguada, 2500-2800 m, 22 Nov 1991, *M. Lewis 40645* (holotype: LPB0000936!;  
 415 isotype MO!).

416 ***Distribution***—Sub-Andean foothills of Bolivia and Peru. *Galianthe boliviana* grows mainly on  
 417 eroded slopes between 1800 and 3150 m of altitude, especially in open forest of *Alnus acuminata*  
 418 Kunth. of Yungas at 2800-3000 m of altitude.

419 ***Taxonomic notes***—*Galianthe boliviana* is similar to *Galianthe dichasia* and *G. cymosa* in having  
 420 cymoidal inflorescences with subglomeriform partial inflorescence, but differs from these in  
 421 possessing stems 20-30 cm tall, with smooth, glabrous, and narrowly winged angles.

422 ***Additional Specimens Examined***—PERU: Cusco, Quispicanchis, Marcapata, 176 km from  
 423 Cusco on road to Maldonado, Marcapata to Cocha, 8 Mar. 1991, 13°25'S 070°54'W, 3150 m,  
 424 *Percy Núñez V. & C. Paycarmayta 13140* (MO).

425 Key to *Galianthe* species with indehiscent mericarps (modified from Cabral & Bacigalupo, 1997)

- 426 1. Stipular sheath tubular, prolonged above the insertion of the corresponding pairs of  
 427 leaves.....2
- 428 1'. Stipular sheath truncate, never surpassing the insertion of the corresponding pairs of  
 429 leaves.....3
- 430 2. Stipular sheath pilose; stems with strongly alate angles; Brazil.....
- 431 .....*G. vaginata* E.L. Cabral &
- 432 Bacigalupo

433	2'. Stipular sheath glabrous; stems without wings.	
434	Brazil.....	<i>G. polygonoides</i> E.L. Cabral & Bacigalupo
435	3. Leaves only with one nerve visible on abaxial face.....	4
436	3'. Leaves plicate nervose.....	7
437	4. Inflorescences pauciflorous, in lax cymoid, partial inflorescences 1-florous. Ecuador,

- 483 13'. Stems much branched; fruit turbinate, 5 mm long;  
 484 Brazil.....  
 485 .....*G. humilis* E.L. Cabral & Bacigalupo

## 486 DISCUSSION

487 *Galianthe palustris* and *G. spicata* share the same taxonomic and nomenclatural history. First,  
 488 they were described under *Diodia*, later they were added to genus *Borreria* (Bacigalupo &  
 489 Cabral, 1996, 1998) due to the presence of homostylous flowers and type of fruit. Later they  
 490 were, transferred to the genus *Spermacoce* (Delprete et al., 2005; Delprete, 2007). In 1998,  
 491 Bacigalupo & Cabral (1998) observed that *G. palustris* (then still *Borreria palustris*) is  
 492 characterized by a thyrsoid inflorescence that is similar to that of *Galianthe*. Despite this  
 493 remarkable observation, the authors decided to transfer the species to genus *Borreria*. Nearly a  
 494 decade later, Delprete et al. (2005) and Delprete (2007) transferred both species to *Spermacoce* in  
 495 an attempt to create a broad genus concept for *Spermacoce*.

Despite overall molecular evidence, *Galianthe spicata* and *G. palustris* also share similar morphological characteristics with the other *Galianthe* species (e.g. spiciform and thyrsoid inflorescences, a bifid stigma and pollen grains with a double reticulum). This last character appears in most species of *Galianthe*, except for *G. bogotensis* (Kunth) E.L. Cabral & Bacigalupo, *G. dichotoma* (Willd. ex Roem. & Schult.) E. L. Cabral & Bacigalupo, and the new species *G. vasquezii*, which have simple reticulum. Pire (1997) hypothesized that in a genus mainly represented by species with double reticulum pollen grains, the simple reticulum is the result of the absence of an infrareticulum persisting only a supareticulum.

Current molecular data indicates that the phylogenetic position of *Diodia palustris* (*Galianthe palustris*) and *D. spicata* (*G. spicata*) make *Galianthe* paraphyletic. The *Galianthe* clade, including both former *Diodia* species, is strongly supported and has two molecularly well-defined clades. The [*Diodia palustris* + *D. spicata*] + *G. brasiliensis* clade is composed only by species with capsules separating into two indehiscent mericarps and which is a diagnostic character of *Galianthe* subgen. *Ebelia*. The sister clade, [*G. eupatorioides* + *G. grandifolia*] + *G. peruviana*, includes species of *Galianthe* subgen. *Galianthe*, and is characterized by fruits with dehiscent valves. Both morphological and molecular data support the transfer of two former *Diodia* species to *Galianthe*, and more specifically in subgen. *Ebelia*. Additionally, and according to present sampling, the two subgenera described by Cabral & Bacigalupo (1997) seem to be monophyletic. The transfer of *Diodia spicata* to *Galianthe* was originally proposed by Dessein (2003), based on fruit, polynological and molecular features.

Even though morphological and molecular data show that three species share several characteristics with *Galianthe* subgen. *Ebelia*, there is a significant difference with the other species of the subgenus. The three species, unlike the remainder, have homostylous flowers. As a result, these results demonstrate the presence of a new floral trait in *Galianthe* and therefore strongly modify the generic concept of the genus.

According to Groeninckx et al. (2009), distyly is often related with double reticulum pollen grains in the tribe Spermacoce. Nevertheless, in the genus *Galianthe* there are some exceptions to this generalization (e.g. *G. bogotensis* (distyly and simple reticulum), *G. spicata* and *G. vasquezii* (homostyly and double reticulum), and *G. palustris* (homostyly and simple reticulum). Cabral & Bacigalupo (1997) mentioned that *G. dichotoma* presents an intermediate state between distyly/homostyly and pollen with simple reticulum. The authors defined this phenomenon as an “unclear dimorphism” (in Spanish “dimorfismo poco manifiesto”). Future studies are necessary in order to clearly define the floral morphs that are present in these species.

# ACKNOWLEDGMENTS

We thank the herbarium curators for providing material, especially James Solomon from MO and Rocio Rojas from HOXA. We also thank HOXA's staff; Rodolfo Vasquez and Thania Carhuaricra for sending us images of *Galianthe vasquezii*'s. We also thank Pedro Cuaranta for his help in the illustration of the new species. The second author thanks Beatriz Galati for the selfless assistance in the observation in MEB (UBA) of the pollen grains, and reproductive structures of *Galianthe palustris* and *G. spicata*. The third author thanks Charlotte Taylor for the invaluable collaboration.
