

# Regulation of $K_{Ca2.3}$ and endothelium-dependent hyperpolarization (EDH) in the rat middle cerebral artery: the role of lipoxygenase metabolites and isoprostanes

**Background and purpose:** In rat middle cerebral arteries, endothelium-dependent hyperpolarization (EDH) is mediated by activation of calcium-activated potassium ( $K_{Ca}$ ) channels specifically  $K_{Ca2.3}$  and  $K_{Ca3.1}$ . Lipoxygenase (LOX) products function as endothelium-derived hyperpolarizing factors (EDHFs) in rabbit arteries by stimulating  $K_{Ca2.3}$ . We investigated if LOX products contribute to EDH in rat cerebral arteries. **Methods:** Arachidonic acid (AA) metabolites produced in middle cerebral arteries were measured using HPLC and LC/MS. Vascular tension and membrane potential responses to SLIGRL were simultaneously recorded using wire myography and intracellular microelectrodes. **Results:** SLIGRL, an agonist at PAR2 receptors, caused EDH that was inhibited by a combination of  $K_{Ca2.3}$  and  $K_{Ca3.1}$  blockade. LOX- inhibition reduced EDH. Soluble epoxide hydrolase (sEH) inhibition enhanced the  $K_{Ca2.3}$  component of EDH. Following NO synthase (NOS) inhibition, the  $K_{Ca2.3}$  component of EDH was absent. Using HPLC, middle cerebral arteries metabolized  $^{14}C$ -AA to 15- and 12-LOX products under control conditions. With NOS inhibition, there was little change in LOX metabolites, but increased F-type isoprostanes. 8-iso-PGF<sub>2 $\alpha$</sub>  inhibited the  $K_{Ca2.3}$  component of EDH. **Conclusions:** LOX metabolites mediate EDH in rat middle cerebral arteries. Inhibition of sEH increases the  $K_{Ca2.3}$  component of EDH. Following NOS inhibition, loss of  $K_{Ca2.3}$  function is independent of changes in LOX production or sEH inhibition but due to increased isoprostane production and subsequent stimulation of TP receptors. These findings have important implications in diseases associated with loss of NO signalling such as stroke; where inhibition of sEH and/or isoprostane formation may of benefit.

15 **Running title: EDH, LOX and isoprostanes**

**Background and purpose.** In rat middle cerebral arteries, endothelium-dependent hyperpolarization (EDH) is mediated by activation of calcium-activated potassium ( $K_{Ca}$ ) channels specifically  $K_{Ca2.3}$  and  $K_{Ca3.1}$ . Lipoxygenase (LOX) products function as endothelium-derived hyperpolarizing factors (EDHFs) in rabbit arteries by stimulating  $K_{Ca2.3}$ . We investigated if LOX products contribute to EDH in rat cerebral arteries.

**Methods** Arachidonic acid (AA) metabolites produced in middle cerebral arteries were measured using HPLC and LC/MS. Vascular tension and membrane potential responses to SLIGRL were simultaneously recorded using wire myography and intracellular microelectrodes.

**Results** SLIGRL, an agonist at PAR2 receptors, caused EDH that was inhibited by a combination of  $K_{Ca2.3}$  and  $K_{Ca3.1}$  blockade. Non-selective LOX- inhibition reduced EDH, whereas inhibition of 12-LOX had no effect. Soluble epoxide hydrolase (sEH) inhibition enhanced the  $K_{Ca2.3}$  component of EDH. Following NO synthase (NOS) inhibition, the  $K_{Ca2.3}$  component of EDH was absent. Using HPLC, middle cerebral arteries metabolized  $^{14}C$ -AA to 15- and 12-LOX products under control conditions. With NOS inhibition, there was little change in LOX metabolites, but increased F-type isoprostanes. 8-iso-PGF $_{2\alpha}$  inhibited the  $K_{Ca2.3}$  component of EDH.

**Conclusions** LOX metabolites mediate EDH in rat middle cerebral arteries. Inhibition of sEH increases the  $K_{Ca2.3}$  component of EDH. Following NOS inhibition, loss of  $K_{Ca2.3}$  function is independent of changes in LOX production or sEH inhibition but due to increased isoprostane production and subsequent stimulation of TP receptors. These findings have important implications in diseases associated with loss of NO signaling such as stroke; where inhibition of sEH and/or isoprostane formation may of benefit.

## 42 Introduction

43 Endothelium dependent hyperpolarization (EDH) is an extremely important vasodilator pathway,  
 44 particularly in resistance size arteries, and has a major role in regulation of blood pressure; as  
 45 such the EDH pathway has become intensively studied and targeting this pathway could result in  
 46 new classes of antihypertensive and possibly antithrombotic therapies . The exact nature of EDH  
 47 is still unresolved but involves several different mechanisms that include release of diffusible  
 48 factors (endothelium derived hyperpolarizing factors; EDHFs), direct myo-endothelial cell  
 49 coupling via gap junctions and increases in extracellular potassium concentration in the myo-  
 50 endothelial space that all result in smooth muscle cell hyperpolarization. The relative  
 51 contribution of each mechanism varies between vascular beds and species .

52  
 53 Despite heterogeneity in the pathway, a feature of EDH responses in most vascular beds is the  
 54 critical role of endothelial cell calcium-activated potassium channels ( $K_{Ca}$ ). Blockade of both  
 55  $K_{Ca2.3}$  ( $SK_{Ca}$ ) and  $K_{Ca3.1}$  ( $IK_{Ca}$ ) is required to fully inhibit EDH responses . In contrast, in the rat  
 56 middle cerebral artery (MCA), inhibition of  $K_{Ca3.1}$  channels alone is sufficient to fully block the  
 57 EDH response obtained but only if NO synthase (NOS) is inhibited .  $K_{Ca2.3}$  channels are  
 58 expressed in the endothelium of MCA and contribute to EDH of smooth muscle cells (SMC) in  
 59 vessels that are able to synthesize NO .  $K_{Ca2.3}$  channel function is lost following inhibition of  
 60 NOS , but can be restored upon inhibition of the thromboxane prostanoid (TP) receptor and  
 61 associated subsequent Rho kinase mediated signalling .

62  
 63 In the MCA, EDH responses are also attenuated by inhibition of  $PLA_2$  suggesting a role for a  
 64 metabolite of arachidonic acid (AA). A similar inhibition of EDH by  $PLA_2$  inhibitors has also  
 65 been reported in peripheral arterial beds including mesenteric and coronary arteries . AA

metabolism is complex and produces a large number of biologically active metabolites that affect vascular tone . AA metabolites produced by the cyclooxygenase (COX), epoxigenase and lipoxygenase (LOX) pathways modulate  $K_{Ca}$ . The 12- and 15-LOX pathways of AA metabolism have been implicated in the EDH response . Metabolites of 15-LOX, 15-hydroxy-11,12-epoxyeicosatrienoic acid (HEETA) and its soluble epoxide hydrolase (sEH) metabolite, 11,12,15-trihydroxyeicosatrienoic acid (THETA), have been characterized as EDHFs in rabbit arteries where they stimulate  $K_{Ca2.3}$  channels . Rats express a LOX that has both 12- and 15-LOX activity . Therefore, it is possible that LOX metabolites acting on  $K_{Ca2.3}$  could also contribute EDH in the rat MCA.

NO can potentially interact with the synthesis of many AA metabolites by binding to the heme group of these enzymes . Therefore, TP receptor-mediated inhibition of  $K_{Ca2.3}$  following inhibition of NOS may be due to altered synthesis of AA metabolites such as thromboxane  $A_2$  ( $TxA_2$ ) or isoprostanes that stimulate the TP receptor. Alternately following inhibition of NOS, there may be a change in production of AA metabolites that normally stimulate  $K_{Ca2.3}$ .

As changes in AA metabolism following inhibition of NOS could potentially affect  $K_{Ca2.3}$  function in the MCA, these studies were designed to identify the AA metabolites and determine if these metabolites contribute to EDH in the MCA. Second, we investigated the effect of NOS inhibition on AA metabolism and if any change in metabolite production contributes to the loss of  $K_{Ca2.3}$  function.

## Materials and Methods

Male Wistar or Sprague Dawley rats (200-300g, circa 8-10 weeks old) were humanely killed in accordance with local ethics committee guidelines. The brain was removed and immediately

placed in ice-cold Krebs' solution. Segments of the middle cerebral artery (~2mm long) were dissected and stored in ice-cold Krebs' for use (usually within 30 min but if first vessel failed to meet the exclusion criteria detailed below a second vessel would be mounted this was never >4 h), with similar size vessels used in all experimental groups.

#### *Simultaneous measurement of membrane potential and tension*

Smooth muscle membrane potential was measured simultaneously with vasomotor responses using isometric recording technique. Segments of MCA (internal diameter ~150  $\mu\text{m}$ ) were mounted in a Mulvany-Halpern myograph (model 400A, Danish Myotechnology) in Krebs' solution containing (mM): NaCl, 118.0, NaCO<sub>3</sub>, 24; KCl, 3.6; MgSO<sub>4</sub>·7H<sub>2</sub>O, 1.2; glucose, 11.0; CaCl<sub>2</sub>, 2.5; gassed with 21% O<sub>2</sub>, 5% CO<sub>2</sub>, balance N<sub>2</sub> and maintained at 37°C. After equilibration for 20 min, vessels were tensioned to 1-1.5mN (approximates wall tension at 60 mmHg). Smooth muscle tension was recorded with an isometric pressure transducer and Powerlab software (ADI, Australia). Vessel viability was assessed by adding exogenous K<sup>+</sup> (15-55 mM, total K<sup>+</sup> concentration); only vessels developing tension of  $\geq 3$  mN were used. Endothelial cell viability was assessed by the ability of an agonist of protease activated receptor 2, SLIGRL (serine, leucine, isoleucine, glycine, arginine, leucine; 20  $\mu\text{M}$ ) to relax spontaneous tone and to hyperpolarize the smooth muscle cell membrane by >15 mV. SLIGRL was chosen to stimulate the endothelium as more commonly used agonists such as ACh are unable to evoke an EDH response in the MCA and purinergic agonists that can stimulate EDH responses evoke constriction via smooth muscle cell action.

All endothelium-dependent responses to SLIGRL (20  $\mu\text{M}$ ) were obtained in resting vessels with no vasoconstrictor stimulus other than spontaneous tone unless stated otherwise. EDH of smooth muscle cells was assessed in the presence of the K<sub>Ca</sub> channel blockers, apamin (K<sub>Ca</sub>2.3, 50 nM),

114 TRAM-34 ( $K_{Ca3.1}$ , 1  $\mu$ M) and iberiotoxin ( $K_{Ca1.1}$ , 100 nM). The effect of  $K_{Ca}$  blockers on EDH  
 115 responses was also assessed after addition of three structurally distinct non-selective inhibitors of  
 116 LOX (ebselen, nordihydroguaiaretic acid (NGDA), both 1  $\mu$ M, and PD146176, 5  $\mu$ M), soluble  
 117 epoxide hydrolase (sEH) inhibitor tAUCB (10  $\mu$ M) and isoprostane isoPGF<sub>2 $\alpha$</sub>  (1  $\mu$ M). Isolated  
 118 EDH responses were obtained in the presence of the NO synthase inhibitor L-NAME (100  $\mu$ M).  
 119 In these experiments, the effect of the  $K_{Ca}$  channel blockers was assessed on EDH responses  
 120 induced by SLIGRL (20  $\mu$ M) in the presence of tAUCB or tempol (100  $\mu$ M). Papaverine (150  
 121  $\mu$ M) was added at the end of each experiment to assess overall tone and all relaxations are  
 122 expressed as a percentage of this maximal relaxation. All drugs were allowed to equilibrate for at  
 123 least 20 min before EDH responses were stimulated. In most experiments, smooth muscle  
 124 membrane potential ( $E_m$ ) and tension were measured simultaneously as previously described,  
 125 using glass microelectrodes (filled with 2 M KCl; tip resistance, 80-120 M $\Omega$ ) to measure  $E_m$ . In  
 126 experiments where vessels were able to synthesise NO we only reported EDH of the smooth  
 127 muscle cell layer as NO was able to evoke relaxation even if EDH was blocked.

#### 128 *Measurement of metabolites of $^{14}$ C-labelled AA*

129 Rat cerebral arteries were dissected, cleaned, cut into 2-3 mm rings, and incubated at 37°C with  
 130 indomethacin (10  $\mu$ M) and vehicle or indomethacin and L-NAME (100  $\mu$ M) in 2 ml of N-2-  
 131 hydroxyethylpiperazine-N'-2-ethanesulfonic acid (HEPES) buffer (mM): 10 HEPES, 150 NaCl, 5  
 132 KCl, 2 CaCl<sub>2</sub>, 1 MgCl<sub>2</sub>, 6 glucose, pH 7.4. After 10 min, [ $^{14}$ C]-AA (0.5  $\mu$ Ci, 10<sup>-7</sup> M) was added,  
 133 incubation was continued for 5 min, and then A23187 (10  $\mu$ M) was added. After 15 min, the  
 134 reaction was stopped with ethanol (15% final concentration). The incubation buffer was removed  
 135 and extracted using Bond Elute octadecylsilyl columns as previously described. The extracts of  
 136 the media were analyzed by reverse phase high-pressure liquid chromatography (HPLC) using a

137 Nucleosil C-18 (5 $\mu$ , 4.6 x 250 mm) column . Solvent system 1 was used to resolve lipoxxygenase  
 138 and epoxyxygenase metabolites and consisted of a 40 min linear gradient (flow rate=1 ml/min) from  
 139 50% solvent B (acetonitrile with 0.1% glacial acetic acid) in solvent A (deionized water) to 100%  
 140 solvent B. Column effluent was collected in 0.2 ml fractions, and the radioactivity was  
 141 determined. In a separate series of incubations, arterial rings were incubated with vehicle or L-  
 142 NAME (100  $\mu$ M) as described above. Following extraction of the media, prostaglandins and  
 143 isoprostanes were resolved using a Nucleosil C-18 column using solvent system 2. This solvent  
 144 system consisted of an 40 min isocratic elution with 31% solvent B (acetonitrile) in solvent A  
 145 (water containing 0.025 M phosphoric acid) followed by a 20 min linear gradient to 100% B and  
 146 a 10 min elution with 100% B. The column eluate was collected in 0.5 ml fractions and  
 147 radioactivity determined. Total radioactivity from a sample was normalized to tissue weight.  
 148 The extracts were analyzed using liquid chromatography-mass spectrometry (LC/MS) with an  
 149 Agilent Model 1100SL mass selective detector and electrospray ionization . Metabolites were  
 150 resolved using a Kromasil C-18 (5  $\mu$ m, 2 x 250 mm) column. Solvent system 3 consisted of a 10  
 151 min linear gradient from 15% solvent B (acetonitrile) in solvent A (water containing 0.005%  
 152 glacial acetic acid) to 60% solvent B in A, a 10 min linear gradient to 80% solvent B in A  
 153 followed by 5 min gradient to 100% B. The flow rate was 0.2 ml/min. The drying gas flow was  
 154 12 l/min. The nebulizer pressure was 35 psig, vaporizer temperature was 325°C and desolvation  
 155 temperature 350°C. The capillary voltage was 3 kV and fragmentor voltage was 120 V.  
 156 Detection was in the negative ion mode. For isoprostanes, the eluate was monitored at m/z 351  
 157 (M-H) for PGE<sub>2</sub>-type isoprostanes and m/z 353 for PGF<sub>2</sub>-type isoprostanes. Comparisons were  
 158 made with the elution times of known isoprostane standards.

# 159 *Data analysis and statistical procedures*

160 Results are expressed as the mean  $\pm$  s.e.m. of  $n$  animals. Tension values are given in mN (always  
161 per 2 mm segment) and  $E_m$  as mV. Vasodilatation is expressed as percentage reduction of  
162 the total vascular tone (spontaneous tone plus vasoconstrictor response), quantified by  
163 relaxation with papaverine (150  $\mu$ M). Graphs were drawn and comparisons made using  
164 one-way ANOVA with Tukeys' post-test or Students' t-test, as appropriate (Prism,  
165 GraphPad).  $P \leq 0.05$  was considered significant.

166

# 167 *Drugs, chemicals, reagents and other materials*

168 Exogenous  $K^+$  was added as an isotonic physiological salt solution in which all the NaCl was  
169 replaced with an equivalent amount of KCl. Concentrations of  $K^+$  used are expressed as final bath  
170 concentration. Ebselen (2-Phenyl-1,2-benzisoselenazol-3(2H)-one), L-NAME ( $N^G$ -nitro-L-  
171 arginine methyl ester), Nordihydroguaiaretic acid (NDGA), papaverine HCl, PD 146176 (6,11-  
172 Dihydro[1]benzothiopyrano[4,3-b]indole), tempol (4-Hydroxy-2,2,6,6-tetramethylpiperidine 1-  
173 oxyl), TRAM-34 (1-[(2-Chlorophenyl)diphenylmethyl]-1H-pyrazole) and U46619 (9,11-  
174 Dideoxy-11 $\alpha$ ,9 $\alpha$ -epoxymethanoprostaglandin  $F_{2\alpha}$ ) were all obtained from Sigma (Poole, U.K.).  
175 Apamin and iberotoxin, from Latoxan (Valence, France). SLIGRL-NH<sub>2</sub> (serine, leucine,  
176 isoleucine, glycine, arginine, leucine) from Auspep (Parkville, Australia). 8-iso PGF<sub>2 $\alpha$</sub>  from  
177 Cayman-Europe (Tallinn, Estonia). tAUCB (*trans*-4-[4-(3-Adamantan-1-yl-ureido)-  
178 cyclohexyloxy]-benzoic acid) was a generous gift from Professor Bruce D. Hammock  
179 (University of California, Davis). All stock solutions (100 mM) were prepared in  
180 dimethylsulfoxide (DMSO) except L-NAME, apamin, iberiotoxin, papaverine and SLIGRL that

were dissolved in 0.9% NaCl and tempol which was dissolved in ultrapure water. Vehicle controls were performed when necessary.

#### Abbreviations

## Results

### *Effect of LOX and sEH inhibition on EDH.*

In our previous studies, control arteries that had not been treated with a NOS inhibitor demonstrate endothelium-dependent hyperpolarization (EDH) that has components from  $K_{Ca2.3}$ ,  $K_{Ca3.1}$  and  $K_{Ca1.1}$  channels. A similar pattern was seen in this study. Control EDH was significantly inhibited only by the combination of the  $K_{Ca3.1}$  inhibitor TRAM-34 and the  $K_{Ca2.3}$  inhibitor apamin; TRAM-34 alone had no significant inhibition alone (Figure 1B); apamin alone was not assessed in this study but our previous studies demonstrate alone it does not have a significant effect on EDH under these conditions (McNeish & Garland 2007; McNeish et al. 2006). The residual EDH was blocked by the inhibitor of  $K_{Ca1.1}$  ( $BK_{Ca}$ ), iberiotoxin.

SLIGRL (20 $\mu$ M) evoked EDH (30.0 $\pm$ 5.5 mV, n=4) that was significantly reduced by the LOX inhibitor nordihydroguaiaretic (NDGA, 1 $\mu$ M; 10.7 $\pm$ 2.3mV; n=4, P<0.05; Figure 1A, C). This hyperpolarization was further reduced by TRAM-34 (4.3 $\pm$ 2.4mV, n=5) but not by subsequent additions of apamin and iberiotoxin (Figure 1B). NDGA also abolished spontaneous tone (1.9 $\pm$ 0.6 Vs 0.2 $\pm$ 0.2 mN, pre- and post-NDGA, respectively, n=4, P<0.05). This relaxation was not associated with significant hyperpolarization (-44.6 $\pm$ 3.0 vs 51.9 $\pm$ 4.3mV, pre- and post-NDGA, respectively, n=4). A structurally distinct blocker of LOX, ebselen (10 $\mu$ M), had similar effects. Ebselen significantly inhibited EDH (28.8 $\pm$ 2.2mV, vs. 15.6 $\pm$ 2.9mV, pre- and post-ebselen, respectively; P<0.05, n=6; Figure 1C). Hyperpolarization that was resistant to ebselen was not significantly reduced by TRAM-34 (Figure 1C) or further addition of apamin but the subsequent addition of iberiotoxin reduced hyperpolarization further (figure 1D). Ebselen also reduced spontaneous tone (0.6  $\pm$  0.0 mN vs 0.3  $\pm$  0.1 mN, pre- and post-ebselen, respectively, n=6, P<0.05) that was not associated with significant hyperpolarization (-44.3 $\pm$ 1.0 vs 49.0 $\pm$ 3.3mV, pre- and post-ebselen, respectively, n=6). A third LOX inhibitor, PD146176 (5  $\mu$ M), also reduced EDH (27.5 $\pm$ 3.1 and 9.8 $\pm$ 2.6 mV pre- and post-PD146176 respectively, n=5, P<0.05). PD146176 also reduced spontaneous tone (1.5 $\pm$ 0.3 and 0.2 $\pm$ 0.1 mN pre- and post-PD146176 respectively, n=5, P<0.05) that was not associated with significant hyperpolarization (-52.1 $\pm$ 3.9 vs -58.7 $\pm$ 4.5 mV, pre- and post-PD146176, respectively, n=5). The similar effect of these three structurally different LOX inhibitors to inhibit EDH and abolish the K<sub>Ca</sub>2.3 component of this response indicates a role for LOX-derived AA metabolites in EDH.

Previous studies indicate that the LOX-derived HEETA is metabolized by sEH to THETA. Inhibition of sEH reduced HEETA metabolism and enhanced EDH to AA suggesting an important role for HEETA in mediating EDH. The inhibitor of sEH, tAUCB (10 $\mu$ M) did not

significantly effect EDH to SLIGRL in control vessels ( $33.5 \pm 5.4$  vs.  $30.8 \pm 6.0$  mV pre- and post-tAUCB, respectively  $n=5$ ). Following inhibition of  $K_{Ca3.1}$  and  $K_{Ca1.1}$  with the combination TRAM-34 and iberiotoxin, the residual hyperpolarization to SLIGRL ( $17.8 \pm 2.8$  mV,  $n=5$ ) is mediated solely by  $K_{Ca2.3}$ . Under these conditions, the  $K_{Ca2.3}$ -mediated hyperpolarization was significantly augmented by tAUCB ( $29.2 \pm 3.6$ ,  $P < 0.05$ ,  $n=6$ , Figure 2A, B). This augmented response is specific for  $K_{Ca2.3}$  since addition of apamin significantly inhibited EDH ( $7.0 \pm 2.0$  mV,  $P < 0.05$ , Figure 2A, B). Therefore, an epoxide-containing LOX metabolite of AA contributes to the  $K_{Ca2.3}$  component of EDH and is normally metabolized by sEH.

#### *Effect of tAUCB and superoxide scavenging on EDH responses in the presence of L-NAME.*

In the presence of the NOS inhibitor L-NAME, inhibition of  $K_{Ca3.1}$  alone abolishes EDH. The absence of a  $K_{Ca2.3}$  component reflects activation of TP receptors. Similarly, in this study, the isolated EDH-mediated response obtained in the presence of L-NAME (hyperpolarization of  $23.1 \pm 4.6$  mV and relaxation of  $74.3 \pm 5.3\%$ ,  $n=8$ ) was significantly attenuated by TRAM-34 alone (hyperpolarization of  $6.5 \pm 1.5$  mV and relaxation of  $25.0 \pm 4.2\%$ ,  $n=5$ ; Figure 2C). Application of tAUCB to TRAM-34-treated arteries failed to recover the EDH response (hyperpolarization of  $4.2 \pm 2.4$  mV and relaxation of  $23.7 \pm 2.7\%$ ,  $n=5$ ; Figure 2C). In the combined presence of L-NAME and tempol, a cell permeable superoxide scavenger, isolated EDH responses to SLIGRL were significantly inhibited only by the combination of TRAM-34 and apamin. Further inhibition of  $K_{Ca1.1}$  with iberiotoxin abolished the residual EDH response (Figure 2D). Thus, tempol restored the  $K_{Ca2.3}$  component to the EDH whereas inhibition of sEH failed to restore this component of EDH.

#### *AA metabolism of the rat middle cerebral artery.*

Since LOX metabolites mediate a component of EDH, we investigated the metabolism of  $^{14}\text{C}$ -AA by cerebral arteries. In arteries treated with the COX inhibitor, indomethacin, to facilitate the identification of LOX metabolites, the products of AA metabolism were resolved by reverse phase HPLC using solvent system 1.  $^{14}\text{C}$ -Labelled metabolites co-migrated with the LOX products THETAs, HEETAs, 15-HETE and 12-HETE (Figure 3A). There were virtually no AA metabolites eluting with the EETs indicating that it is unlikely that the middle cerebral artery produces cytochrome P450 epoxygenase products. In the presence of the NOS inhibitor L-NAME, there was a significant change in the profile of AA metabolism. Metabolites co-migrating with 12-HETE and 15-HETE were markedly increased whereas the metabolites co-migrating with the THETAs and HEETAs increased slightly (Figure 3B). Arteries were also incubated in the presence and absence of L-NAME and the metabolites resolved by reverse phase HPLC using solvent system 2 that resolves COX metabolites and isoprostanes. Indomethacin was not present in these incubations. Metabolites comigrating with 6-keto  $\text{PGF}_{1\alpha}$ , 8-iso- $\text{PGF}_2$  and 12-HETE were detected (Figure 4). A  $^{14}\text{C}$ -metabolite comigrating with  $\text{TxB}_2$  was not observed. Following L-NAME treatment, there was also a marked increase in polar metabolites eluting in fractions 5-10 and possibly 8-iso- $\text{PGF}_2$ , eluting in fractions 33-34 (Figure 4). Isoprostane synthesis was confirmed by LC/MS analysis. Extracts were purified by reverse phase HPLC using solvent system 3 and the eluate monitored by selected ion monitoring of  $m/z$  351 for  $\text{PGE}_2$ -type isoprostanes and  $m/z$  353 for  $\text{PGF}_2$ -type isoprostanes (Figure 5). The production of 8-iso- $\text{PGE}_2$  was similar in control and L-NAME-treated arteries (380 and 335 ng/ml, respectively; Figure 5A), whereas 8-iso- $\text{PGF}_2$  production increased 3-fold with L-NAME treatment (179 and 583 ng/ml, respectively; Figure 5B). In addition, several unidentified  $\text{PGF}_2$ -type isoprostanes were produced by cerebral arteries and were increased by L-NAME (Figure 5B).

## 280 *Effect of 8-isoprostane $F_2$ on EDH*

281 Since cerebral arteries synthesize isoprostanes, and L-NAME increased their production, we  
 282 investigated the effects of 8-iso-PGF<sub>2</sub> on vascular tone and EDH. 8-iso-PGF<sub>2</sub> caused  
 283 concentration-dependent contraction of cerebral arteries that was fully inhibited by the TP  
 284 receptor antagonist SQ 29,548 (10μM, Figure 6A).

285

286 In control vessels, exogenous application of 8-iso-PGF<sub>2</sub> (1 μM) caused significant depolarization  
 287 and constriction (Em -49.9±2.5 Vs -40.7±2.5 mV and tension 1.0±0.2 Vs 3.9±0.3 mN pre- and  
 288 post-8-iso-PGF<sub>2</sub>, respectively, n=9, P<0.05) but did not significantly affect SLIGRL-induced  
 289 EDH (28.0±2.7 vs. 23.7± 2.3mV, pre- and post-8-iso-PGF<sub>2</sub> respectively, n=9; Figure 6B, C). In  
 290 the presence of 8-iso-PGF<sub>2</sub>, EDH was significantly inhibited by TRAM-34 alone (13.6±2.8 mV,  
 291 P<0.05, n=5; Figure 6BC) whereas apamin alone had no effect (25.5±5.9mV, n=4; Figure 6C);  
 292 nor did it have any additional affect in combination with TRAM-34 (9.6±1.1mV, n=9; Figure  
 293 6C). The residual hyperpolarization was blocked by addition of iberiotoxin (3.2± 0.8mV, n=7;  
 294 Figure 6C).

295

## 296 **Discussion**

297 This study is the first to demonstrate that a LOX metabolite(s) of AA, contributes to endothelium-  
 298 dependent hyperpolarization (EDH) in the rat middle cerebral artery and thus may be the, as yet,  
 299 unidentified AA metabolite involved in EDH responses in the middle cerebral artery. Following  
 300 inhibition of NOS with L-NAME, the profile of AA metabolism is altered. There is no change in  
 301 production of LOX products; however, L-NAME increased 8-iso-PGF<sub>2</sub> production and the  
 302 production of other iso-PGF<sub>2</sub> isomers. We suggest that the increase in isoprostane formation  
 303 causes the TP receptor-dependent loss of K<sub>Ca</sub>2.3-mediated component of EDH, a phenomenon we  
 304 had previously attributed to TxA<sub>2</sub>.

305

306 The findings that 15-LOX metabolites, namely HEETA and THETA, contribute to the EDH  
307 response in rabbit arteries lead us to investigate whether these metabolites contributed to EDH in  
308 the rat middle cerebral artery. This was of particular interest as EDH responses in this artery have  
309 a component dependent upon an unidentified AA metabolite . Analysis of AA metabolism by the  
310 middle cerebral artery indicates LOX products are generated whereas epoxygenase metabolites  
311 such as EETs are not. In control arteries, EDH induced by SLIGRL-NH<sub>2</sub> is significantly  
312 attenuated by three structurally distinct inhibitors of LOX enzymes. These findings clearly  
313 indicate that EDH in this artery is mediated, at least in part, by LOX metabolites.

314

315 K<sub>Ca</sub> channels mediate the EDH responses to LOX metabolites; the most likely candidates are  
316 either 12-HETE, a 12-LOX metabolite, or HEETA and THETA, 15-LOX metabolites . These  
317 metabolites are all produced by the rat middle cerebral artery consistent with the expression of a  
318 12/15-LOX. Interestingly, 12-HETE (30 nM) had no effect on membrane potential or tone in  
319 cerebral arteries (data not shown). Therefore, the 15-LOX products, HEETA or THETA, are most  
320 likely the AA metabolites that contribute to EDH responses in this artery.

321

322 HEETA and THETA stimulate hyperpolarization of rabbit arteries by direct stimulation of  
323 K<sub>Ca2.3</sub> . As HEETA is rapidly metabolized by sEH to THETA, it is difficult to distinguish  
324 between the activities of these two eicosanoids. In order to ascertain which of these metabolites  
325 contributes to EDH, we used a selective sEH inhibitor tAUCB ; tAUCB does not affect total  
326 EDH but selectively augments the K<sub>Ca2.3</sub> component of EDH. As inhibition of sEH prevents the  
327 rapid breakdown of HEETA to THETA, it is likely that the HEETA, not THETA, is the 15-LOX  
328 product involved in EDH. In rabbit arteries, both these LOX products directly stimulate K<sub>Ca2.3</sub>  
329 located on the SMC layer and thus act as diffusible EDHFs. However, such an action is unlikely

in the rat middle cerebral artery as  $K_{Ca2.3}$  are expressed solely on the endothelium . Thus, it is more likely that HEETA contribute to EDH by acting as an intracellular or autocrine modulators of endothelial  $K_{Ca2.3}$ , as proposed for other AA metabolites involved in EDH responses such as EETs . More recently, metabolites of AA have also been shown to have effects on transient receptor potential channels evoking subsequent  $K_{Ca}$  channel activation and dilation .

Under the experimental conditions described above, the middle cerebral artery produces NO and the  $K_{Ca2.3}$  channel contributes to EDH. However, under conditions where NOS is blocked to observe the EDH response in isolation, the  $K_{Ca2.3}$  channel component of hyperpolarization is lost and only  $K_{Ca3.1}$  channels contribute to the EDH response . The loss of the  $K_{Ca2.3}$  channel component involves stimulation of TP receptors . Since LOX products appear to selectively augment  $K_{Ca2.3}$  channels, we postulated that TP-mediated inhibition of this channel may be due to a reduction in LOX metabolites. However, following NOS inhibition, there was actually an increase in the AA metabolites corresponding to HEETA, THETA and HETEs. Inhibition of sEH (a treatment that would be expected to protect HEETA production and thus  $K_{Ca2.3}$  channel activation) failed to restore  $K_{Ca2.3}$  channel function when NOS was inhibited. Therefore, loss of  $K_{Ca2.3}$  function following NOS inhibition does not involve decreased production of LOX metabolites. This finding supports a previous study that demonstrated inhibition of LOX has no effect on EDH responses following inhibition of NOS .

A potential explanation for the loss of  $K_{Ca2.3}$  channel function following NOS inhibition, despite increased production of LOX metabolites, is that TP mediated signaling mechanisms overcome the actions of LOX metabolites. TP receptor stimulation inhibits  $K_{Ca2.3}$ -mediated responses in control arteries able to synthesize NO by a Rho kinase dependent mechanism . Therefore, we wished to confirm that synthesis of the endogenous activator of TP receptors,  $TxA_2$ , is increased

following NOS synthase inhibition, as previously suggested . Surprisingly, we did not detect TxA<sub>2</sub> production with, or without, NOS inhibition. However, following NOS inhibition there was an increase in production of isoprostanes which also stimulate TP receptors .

The most likely source of isoprostanes is the non-enzymatic reaction of either free or esterified AA with reactive oxygen species such as superoxide . Due to our sampling technique of measuring isoprostanes in the incubation medium it is likely that we were measuring isoprostanes produced from free AA, (although we cannot eliminate the possibility that esterified isoprostanes were also released into the medium); however the endothelium is the mostly likely source of the isoprostanes as it is the major source of AA metabolites in vascular tissues . Interestingly, superoxide production is high in the cerebral vasculature when compared to systemic vessels due to increased expression of NADPH oxidase . As NO reacts rapidly with superoxide, it is conceivable NOS inhibition in the middle cerebral artery increases free superoxide produced from NADPH oxidase and therefore isoprostane synthesis leading to stimulation of TP receptors and loss of K<sub>Ca</sub>2.3 function. The superoxide scavenger tempol prevented loss of K<sub>Ca</sub>2.3 function following inhibition of NOS supporting this hypothesis. Furthermore, using LC/MS, we detected increased production of 8-iso-PGF<sub>2</sub> and several as yet unidentified PGF<sub>2</sub>-type isoprostanes following NOS inhibition. While the source of superoxide was not investigated in this study a similar increase in isoprostane production following inhibition of NOS has been observed kidneys where it was reversed by tempol and knock out of gp91 phox , we thus speculate that a similar NADPH dependent mechanism is responsible for increased isoprostane production cerebral arteries. In arteries not treated with a NOS inhibitor, exogenous 8-iso-PGF<sub>2</sub> constricted the middle cerebral artery via a TP receptor dependent mechanism and mimicked the ability of other TP receptor agonists to inhibit the K<sub>Ca</sub>2.3 component of EDH. Thus, increased production

of 8-iso-PGF<sub>2</sub> following NOS inhibition is likely to cause the loss of the K<sub>Ca</sub>2.3 component of EDH.

The data are summarized in Figure 7, they indicate the novel finding that LOX metabolites of AA, most likely HEETA, contribute to EDH in the middle cerebral artery and that inhibition of sEH with the selective inhibitor tAUCB increases the K<sub>Ca</sub>2.3 component of hyperpolarization. However, the loss of K<sub>Ca</sub>2.3 function following inhibition of NOS is not restored by tAUCB treatment. Instead, NOS inhibition increases F-type isoprostane production resulting in TP receptor stimulation (Figure 7), the loss of K<sub>Ca</sub>2.3 responses and elimination of the effect of HEETA. These findings may have important implications in diseases associated with loss of NO signaling such as stroke and coronary artery disease where increased isoprostane production has been detected . This pathway may be related to the severity of the disease . Our data indicate that inhibition of sEH may not be an effective treatment for cerebrovascular disease but prevention of isoprostane formation may be beneficial.

536 **Figure 1:** Effect of lipoxygenase inhibition on endothelium-dependent hyperpolarization (EDH)  
 537 evoked by SLIGRL (20 $\mu$ M) in rat middle cerebral arteries that are able to synthesize NO. (A) An  
 538 original, representative trace showing control EDH (upper panel) and the effect of the non-  
 539 selective lipoxygenase inhibitor NDGA (1  $\mu$ M) on EDH (lower panel). Also shown are Bar  
 540 graphs showing (B) control EDH and the effect of lipoxygenase inhibitors NDGA (C) and  
 541 ebselen (1 $\mu$ M) (D) as well as the effect subsequent inhibition of K<sub>Ca</sub>3.1 (TRAM-34) K<sub>Ca</sub>2.1  
 542 (apamin) and K<sub>Ca</sub>1.1 (iberiotoxin) on EDH. Control EDH was only inhibited following inhibition  
 543 of K<sub>Ca</sub>2.3 and K<sub>Ca</sub>3.1 in the combined presence of apamin and TRAM-34, respectively. NDGA  
 544 and ebselen significantly inhibited EDH, the residual hyperpolarization was inhibited by TRAM-  
 545 34 alone, subsequent addition of apamin and IbTx had no significant additional effect. \*P<0.05  
 546 indicates a significant difference from control.

**Figure 2:** The effect of the sEH inhibitor tAUCB on the  $K_{Ca2.3}$  component of endothelium-dependent hyperpolarization (EDH) in rat middle cerebral arteries able to synthesize NO. (A) Original traces of  $K_{Ca2.3}$ -mediated hyperpolarization obtained in the presence of: the  $K_{Ca3.1}$  inhibitor TRAM-34 and  $K_{Ca1.1}$  inhibitor iberiotoxin (upper trace), the subsequent addition of tAUCB (middle trace) and the combination of tAUCB and the  $K_{Ca2.3}$  inhibitor, apamin. (B) Bar graph showing control EDH,  $K_{Ca2.3}$  dependent EDH in the presence and absence of tAUCB and further addition of apamin. The  $K_{Ca2.3}$ -dependent hyperpolarization was significantly smaller than control EDH and was potentiated by tAUCB this hyperpolarization was completely abolished by apamin indicating that it was mediated solely by  $K_{Ca2.3}$ . (C) Bar Graph showing the SLIGRL-induced EDH mediated hyperpolarization (left panel) and relaxation (right panel) in the presence of the NOS inhibitor L-NAME. TRAM-34 significantly attenuated EDH responses and the subsequent addition of t-AUCB had no further effect. Under these conditions, there is no contribution from  $K_{Ca2.3}$  channels and tAUCB failed to restore the function of this channel. (D) Bar graphs showing the SLIGRL-induced EDH mediated hyperpolarization (left panel) and relaxation (right panel) in the presence tempol and the NOS inhibitor L-NAME. Tempol restored a  $K_{Ca2.3}$  component to the EDH response and also revealed a  $K_{Ca1.1}$  component (n=5). \*P<0.05 indicates a significant difference from control,  $\Psi$ P<0.05 indicates a significant difference from TRAM-34 + IbTx ( $K_{Ca2.3}$  hyperpolarization).

566 **Figure 3:** Effect of the NOS inhibitor L-NAME on arachidonic acid metabolism by rat cerebral  
 567 arteries. Arteries were incubated with  $^{14}\text{C}$ -AA and indomethacin in the absence (A) and presence  
 568 of L-NAME (B). Metabolites were extracted and separated by reverse-phase HPLC, solvent  
 569 system1. Migration times of known standards are shown on each chromatogram. CPM, counts  
 570 per minute, THETA, trihydroxyeicosatrienoic acid; HEETA, hydroxyepoxyeicosatrienoic acid;  
 571 HETE, hydroxyeicosatetraenoic acid; 14,15-EET, 14,15-epoxyeicosatrienoic acid; AA,  
 572 arachidonic acid.  
 573

574 **Figure 4:** Effect of L-NAME on arachidonic acid metabolism by rat cerebral arteries. Arteries  
 575 were incubated with  $^{14}\text{C}$ -labeled arachidonic acid in the absence (Control, solid line) and presence  
 576 of L-NAME (100 mM) (dotted line). Metabolites were extracted and separated by reverse-phase  
 577 HPLC, solvent system 2. Migration times of known standards are shown on each chromatogram.  
 578 CPM, counts per minute, PG, prostaglandin; TX, thromboxane; HETE, hydroxyeicosatetraenoic  
 579 acid; AA, arachidonic acid.

580

581 **Figure 5:** Effect of L-NAME on iso PGE<sub>2</sub> and iso PGF<sub>2</sub> production of rat cerebral arteries.  
 582 Arteries were incubated with AA and indomethacin in the absence and presence of L-NAME.  
 583 Metabolites were extracted and analyzed by liquid chromatography-mass spectrometry. Selected  
 584 ion chromatogram *m/z* 351 (iso PGE<sub>2</sub>) (C) and *m/z* 353 (iso PGF<sub>2</sub>) (D). Migration times of known  
 585 standards are shown on each chromatogram. \*indicates a marked change in production following  
 586 treatment with L-NAME.  
 587

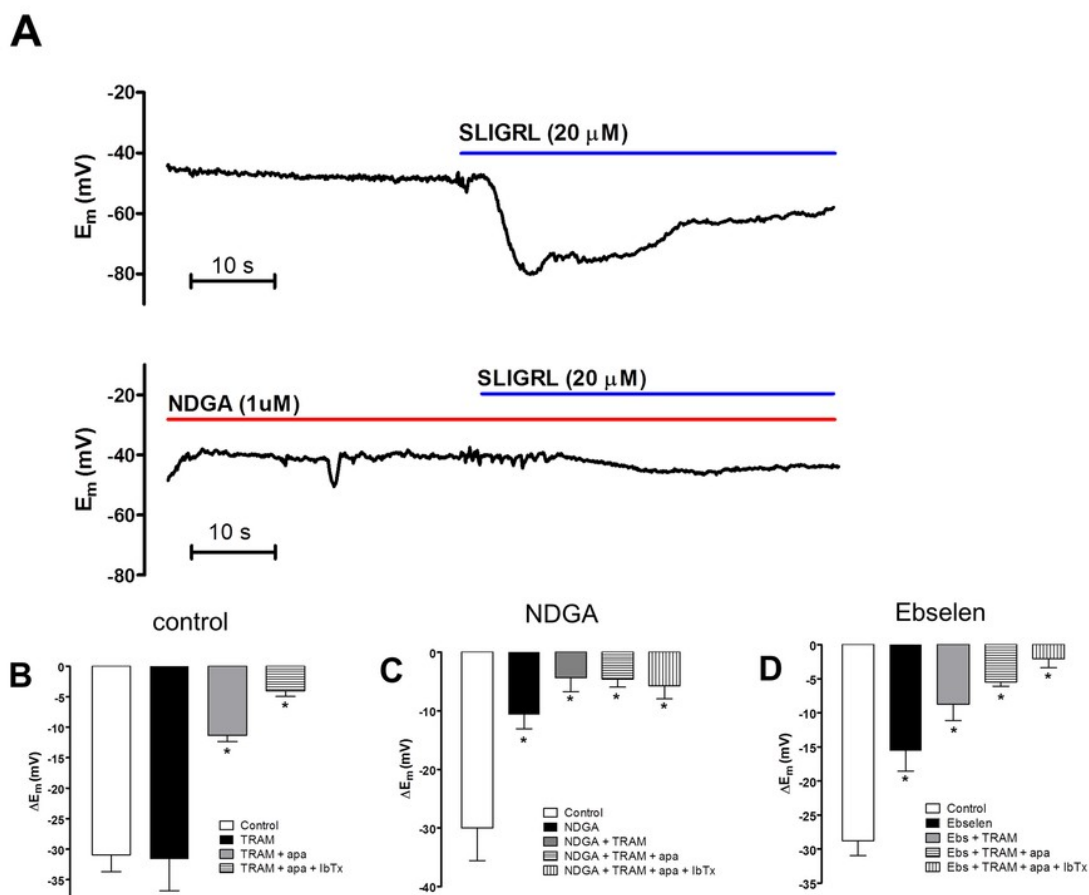

**Figure 6:** Effect of isoprostane  $F_{2\alpha}$  (8-iso PGF) on middle cerebral arteries. (A) Concentration-response curve showing constriction produced by 8-iso PGF in rat middle cerebral arteries that were able to synthesize NO. This constriction was completely blocked by the selective TP antagonist SQ 29,543. (B) Original traces showing the effect of pre-incubation of 8-iso PGF<sub>2</sub> on EDH evoked by SLIGRL (20 $\mu$ M) in rat middle cerebral arteries that were able to synthesize NO. 8-iso PGF<sub>2</sub> did not significantly affect control EDH (upper panel) but subsequent inhibition of KCa<sub>2.3</sub> (TRAM-34; 1  $\mu$ M) virtually abolished EDH (lower panel) the vessel viability was assessed by addition of 15mM K<sup>+</sup> which evokes endothelium-independent hyperpolarization and relaxation (C) Bar graph showing the effect of 8-iso PGF on EDH. Control EDH is unaffected by 8-iso PGF, TRAM-34 alone significantly inhibited EDH and apamin is without effect. The combination of apamin and TRAM-34 had no further effect to TRAM-34 alone. The data shows that 8-iso PGF<sub>2</sub> inhibits the K<sub>Ca2.3</sub> component of EDH normally seen under these conditions. \*P<0.05 indicates a significant difference from control.  $\Psi$ P<0.05 indicates a significant difference from 8-iso-PGF<sub>2 $\alpha$</sub> .

**Figure 7:** Schematic diagram showing the role of LOX products on EDH responses in the middle cerebral artery and the proposed effect that inhibition of NOS and the resultant increase in isoprostane production has on the EDH response. **(1)** Under conditions where middle cerebral arteries can synthesize NO, metabolism of AA by LOX produces HEETA which is metabolized by sEH to THETA both can activate  $K_{Ca2.3}$  channels; as tAUCB augments the  $K_{Ca2.3}$  response HEETA is likely to be the metabolite involved **(2)**. Under these conditions the EDH response also involves activation of  $K_{Ca3.1}$  and  $K_{Ca1.1}$  channels to produce smooth muscle cell hyperpolarization and relaxation **(3)**. When NO is synthesized **(4)** it rapidly reacts with superoxide production of isoprostanes, when NOS is inhibited **(5)** this inhibitory effect of NO on isoprostane production is reduced (N.B. endothelial cells are the major source of vascular AA metabolites but it is possible NO prevents isoprostane production in SMCs), the subsequent stimulation of the TP receptor **(6)** inhibits the  $K_{Ca2.3}$  component of EDH as we have previously reported (McNeish & Garland 2007, McNeish et al. 2012). Solid lines/arrows represent known pathways, dashed lines indicate possible/unconfirmed, pathways green arrows are stimulatory pathways, red lines/text represent inhibitory pathways/blocking agents. EC, endothelial cell; SMC, smooth muscle cell

# Figure 1

Effect of lipoxygenase inhibition on endothelium-dependent hyperpolarization (EDH) evoked by SLIGRL (20 $\mu$ M) in rat middle cerebral arteries that are able to synthesize NO

A) An original, representative trace showing control EDH (upper panel) and the effect of the non-selective lipoxygenase inhibitor NDGA (1  $\mu$ M) on EDH (lower panel). Also shown are Bar graphs showing (B) control EDH and the effect of lipoxygenase inhibitors NDGA (C) and ebselen (1 $\mu$ M) (D) as well as the effect subsequent inhibition of KCa3.1 (TRAM-34) KCa2.1 (apamin) and KCa1.1 (iberiotoxin) on EDH. Control EDH was only inhibited following inhibition of KCa2.3 and KCa3.1 in the combined presence of apamin and TRAM-34, respectively. NDGA and ebselen significantly inhibited EDH, the residual hyperpolarization was inhibited by TRAM-34 alone, subsequent addition of apamin and IbTx had no significant additional effect. \*P<0.05 indicates a significant difference from control.

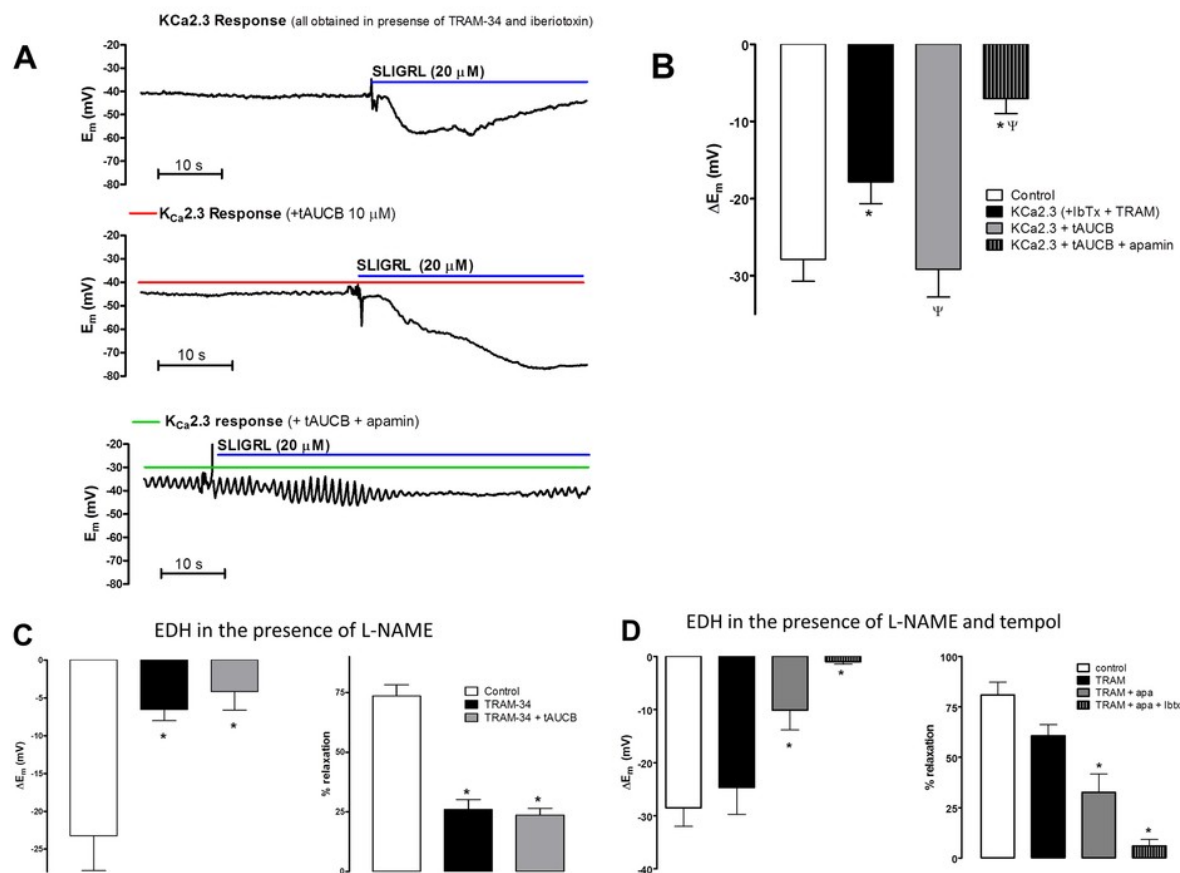

## Figure 2

The effect of the sEH inhibitor tAUCB on the  $K_{Ca2.3}$  component of endothelium-dependent hyperpolarization (EDH) in rat middle cerebral arteries able to synthesize NO.

(A) Original traces of  $K_{Ca2.3}$ -mediated hyperpolarization obtained in the presence of: the  $K_{Ca3.1}$  inhibitor TRAM-34 and  $K_{Ca1.1}$  inhibitor iberiotoxin (upper trace), the subsequent addition of tAUCB (middle trace) and the combination of tAUCB and the  $K_{Ca2.3}$  inhibitor, apamin. (B) Bar graph showing control EDH,  $K_{Ca2.3}$  dependent EDH in the presence and absence of tAUCB and further addition of apamin. The  $K_{Ca2.3}$ -dependent hyperpolarization was significantly smaller than control EDH and was potentiated by tAUCB this hyperpolarization was completely abolished by apamin indicating that it was mediated solely by  $KCa2.3$ . (C) Bar Graph showing the SLIGRL-induced EDH mediated hyperpolarization (left panel) and relaxation (right panel) in the presence of the NOS inhibitor L-NAME. TRAM-34 significantly attenuated EDH responses and the subsequent addition of t-AUCB had no further effect. Under these conditions, there is no contribution from  $K_{Ca2.3}$  channels and tAUCB failed to restore the function of this channel. (D) Bar graphs showing the SLIGRL-induced EDH mediated hyperpolarization (left panel) and relaxation (right panel) in the presence tempol and the NOS inhibitor L-NAME. Tempol restored a  $KCa2.3$  component to the EDH response and also revealed a  $KCa1.1$  component ( $n=5$ ). \* $P<0.05$  indicates a significant difference from control,  $P<0.05$  indicates a significant difference from TRAM-34 + IbTx ( $KCa2.3$  hyperpolarization).

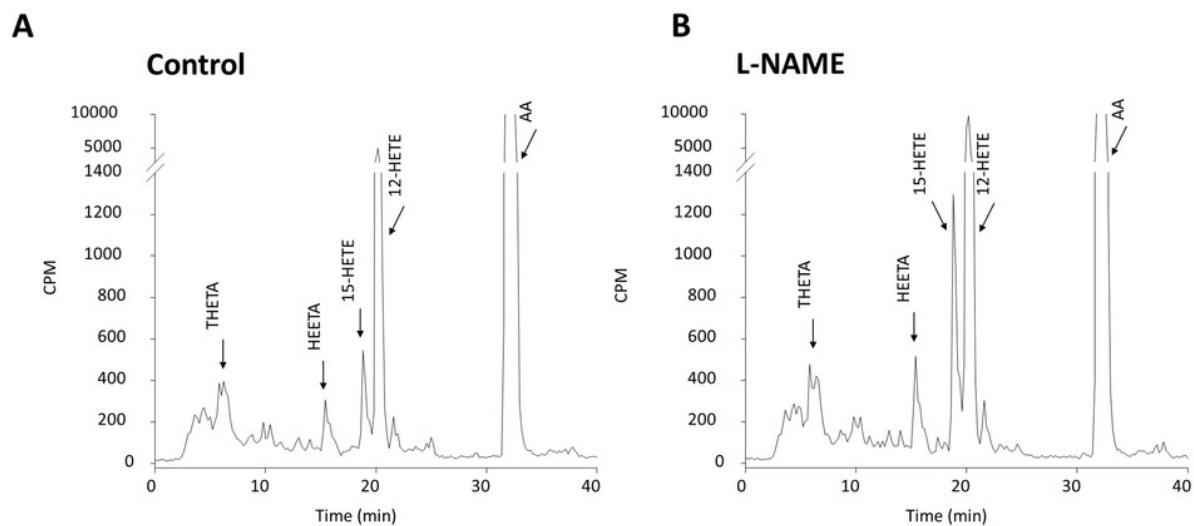

# Figure 3

Effect of the NOS inhibitor L-NAME on arachidonic acid metabolism by rat cerebral arteries

Arteries were incubated with  $^{14}\text{C}$ -AA and indomethacin in the absence (A) and presence of L-NAME (B). Metabolites were extracted and separated by reverse-phase HPLC, solvent system1. Migration times of known standards are shown on each chromatogram. CPM, counts per minute, THETA, trihydroxyecosatrienoic acid; HEETA, hydroxyepoxyecosatrienoic acid; HETE, hydroxyecosatetraenoic acid; 14,15-EET, 14,15-epoxyecosatrienoic acid; AA, arachidonic acid.

# Figure 4

## Effect of L-NAME on arachidonic acid metabolism by rat cerebral arteries

Arteries were incubated with  $^{14}\text{C}$ -labeled arachidonic acid in the absence (Control, solid line) and presence of L-NAME (100 mM) (dotted line). Metabolites were extracted and separated by reverse-phase HPLC, solvent system 2. Migration times of known standards are shown on each chromatogram. CPM, counts per minute, PG, prostaglandin; TX, thromboxane; HETE, hydroxyeicosatetraenoic acid; AA, arachidonic acid.

# Figure 5

Effect of L-NAME on iso PGE<sub>2</sub> and iso PGF<sub>2</sub> production of rat cerebral arteries

Arteries were incubated with AA and indomethacin in the absence and presence of L-NAME.

Metabolites were extracted and analyzed by liquid chromatography-mass spectrometry.

Selected ion chromatogram m/z 351 (iso PGE<sub>2</sub>) (A) and m/z 353 (iso PGF<sub>2</sub>) (B). Migration times of known standards are shown on each chromatogram. \*indicates a marked change in production following treatment with L-NAME.

**A**  $m/z$  351 (iso  $\text{PGE}_2$ )

**B**  $m/z$  353 (iso  $\text{PGF}_2$ )

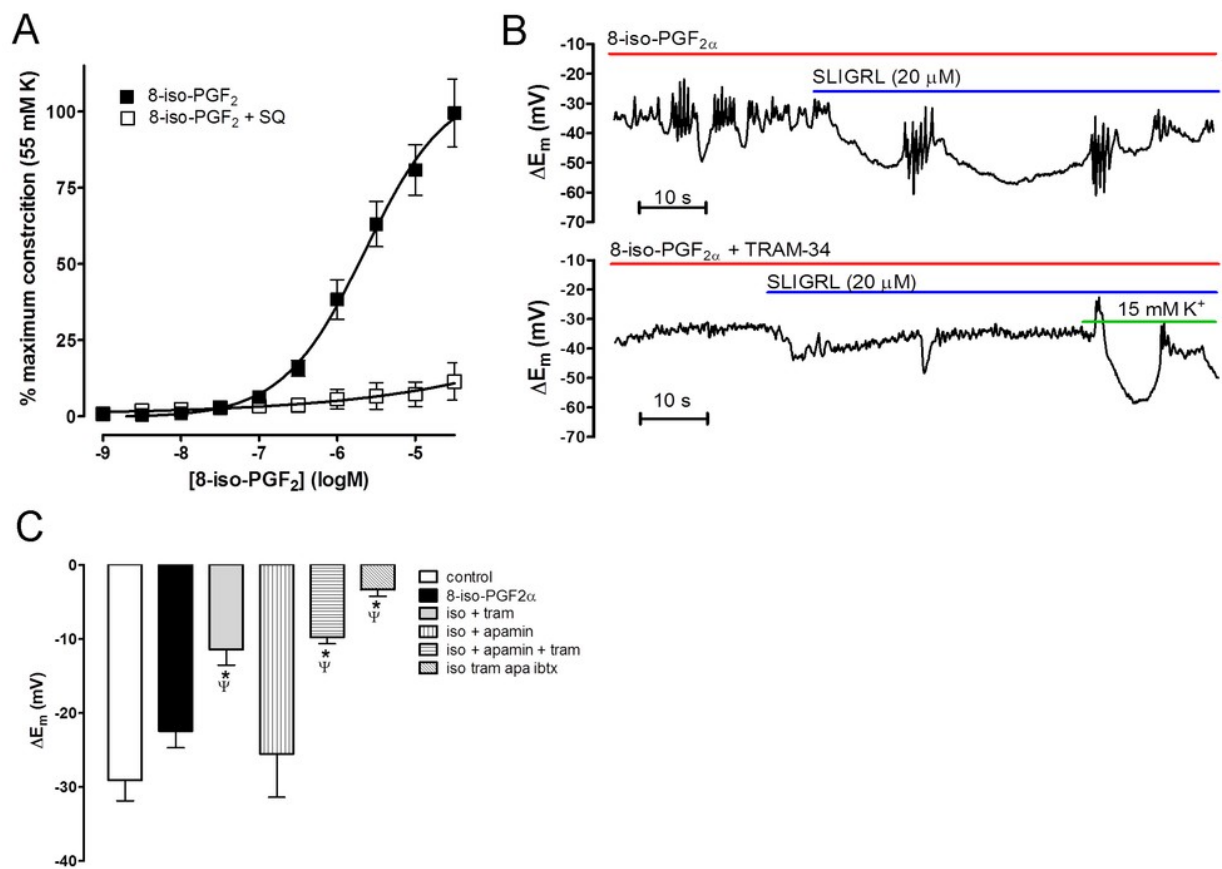

# Figure 6

Effect of isoprostone  $F_{2\alpha}$  (8-iso PGF) on middle cerebral arteries

(A) Concentration-response curve showing constriction produced by 8-iso PGF in rat middle cerebral arteries that were able to synthesize NO. This constriction was completely blocked by the selective TP antagonist SQ 29,543. (B) Original traces showing the effect of pre-incubation of 8-iso PGF<sub>2</sub> on EDH evoked by SLIGRL (20 $\mu$ M) in rat middle cerebral arteries that were able to synthesize NO. 8-iso PGF<sub>2</sub> did not significantly affect control EDH (upper panel) but subsequent inhibition of KCa<sub>2.3</sub> (TRAM-34; 1  $\mu$ M) virtually abolished EDH (lower panel) the vessel viability was assessed by addition of 15mM K<sup>+</sup> which evokes endothelium-independent hyperpolarization and relaxation (C) Bar graph showing the effect of 8-iso PGF on EDH.
