Nosema apis and *Nosema ceranae* are the two main microsporidian parasites causing nosematosis in honey bee *Apis mellifera*. The aim of the present study is to investigate the presence of *Nosema apis* and *Nosema ceranae* in the area of Bulgaria. The 16S (SSU) rDNA gene region was chosen for analysis. A duplex PCR assay was performed on 108 honey bee samples from three different parts of the country (South, North and West Bulgaria). The results showed that the samples from the northern part of the country were with the highest prevalence (77.2%) for *Nosema ceranae* while those from the mountainous parts (the Rodopa Mountains, South Bulgaria) were with the lowest rate (13.9%). Infection with *Nosema apis* alone and co-infection *N. apis/N. ceranae* were not detected in any samples. These findings suggest that *Nosema ceranae* is the dominant species in the Bulgarian honey bee. It is not known when the introduction of *Nosema ceranae* in Bulgaria has occurred, but like in the rest of the world, this species has become the dominant one in Bulgarian *Apis mellifera*. In conclusion, this is the first report for molecular detection of *Nosema* infection of honey bee in Bulgaria. The results showed that *N. ceranae* is the main *Nosema* species in Bulgaria.

19   **Abstract**

20   *Nosema apis* and *Nosema ceranae* are the two main microsporidian parasites causing

21   nosematosis in honey bee *Apis mellifera*. The aim of the present study is to investigate the

22   presence of *Nosema apis* and *Nosema ceranae* in the area of Bulgaria. The 16S (SSU) rDNA

23   gene region was chosen for analysis. A duplex PCR assay was performed on 108 honey bee

24   samples from three different parts of the country (South, North and West Bulgaria). The results

25   showed that the samples from the northern part of the country were with the highest prevalence

26   (77.2%) for *Nosema ceranae* while those from the mountainous parts (the Rodopa Mountains,

27   South Bulgaria) were with the lowest rate (13.9%). Infection with *Nosema apis* alone and co-

28   infection *N. apis/N. ceranae* were not detected in any samples. These findings suggest that

29   *Nosema ceranae* is the dominant species in the honey bee in Bulgaria. It is not known when the

30   introduction of *Nosema ceranae* in Bulgaria has occurred, but like in the rest of the world, this

31   species has become the dominant one in Bulgarian *Apis mellifera*.

32   In conclusion, this is the first report for molecular detection of *Nosema* infection of honey bee

33   in Bulgaria. The results showed that *N. ceranae* is the main *Nosema* species in Bulgaria.

34   **Introduction**

35   The Western honey bee (*Apis mellifera* L., Hymenoptera: Apidae) is a species of crucial

36   economic, agricultural and environmental importance. The biological significance of bees is

37   rooted in the fact that they are main pollinators in the natural environment (Barrios et al., 2016;

38   Ballantyn et al., 2017). About 80% of the pollination of entomophilous plants is carried out by

39   *Apis mellifera*. In all crops, active pollination significantly increases their yields (Partap, 2011).

40   On the other hand honey bees are a valuable economic asset due to the ensemble of their

41   products which includes honey, bee pollen, propolis, royal jelly, and bee venom, used by humans

42   for food and treatment (Pasupuleti et al., 2017; Sforcin et al., 2017).

43   Bulgaria has long-standing traditions in the production of honey and bee products, a

44   precondition for which is the varied and rich vegetation of the Balkan Peninsula suitable for the

45   production of honey and also the favorable natural, climatic and ecological conditions.

46   Honey bee colonies suffer from numerous pathogens. These include various bacteria, viruses,

47   fungi and endo- and ecto-parasites. Some of them, microsporidians, are obligate intracellular

48   parasites belonging to the kingdom Fungi (Keeling and McFadden, 1998; Hirt et al., 1999; Sina

49   et al., 2005*). Nosema* is a microsporidian genus causing an infection called Nosemosis of adult

50   honey bees (Klee et al., 2007). Only two main species of *Nosema* causing infection in *Apis*

51   *mellifera* have been recognized – *Nosema apis* (Zander, 1909) and *Nosema ceranae* (Fries et al.,

52   1996). It is well known that *N. apis* is specific for the Western honey bee, *Apis mellifer*a L.,

53   whilst the Eastern honey bee *Apis cerana* harbours *Nosema ceranae* (Fries et al., 1996).

54   However, many recent investigations have revealed that *N. ceranae* is not restricted only to *A.*

55   *cerana*, but it transferred to *A. mellifera*, and even became a dominant species in many parts in

56   the world (Klee et al., 2007; Paxton et al., 2007; Chen et al., 2008; Invernizzi et al., 2009;

57   Tapaszti et al., 2009; Stevanovic et al., 2010; Gajger et al., 2010; Ansari et al., 2017; Papini et al.,

58   2017). The exact time and transmission route of transfer of *N. ceranae* from *A. cerana* to *A.*

59   *mellifera* is not known . It is possible that during the last decades, the rapid, long-distance

60   dissemination of *N. ceranae* is likely due to the transport of infected honey bees and/or by the

61   increased mobility of people, goods and livestock. Recently, a so called "Colony Collapse

62   Disorder" (CCD) disease has been described in the United States (Chen et al., 2008) and Europe

63   (Topolska et al., 2008). The *Nosema ceranae* was suspected to one of the contributor to this

64   illness, especially winter colony loses (Klee et al., 2007).

65   There are two main techniques for identifying *Nosema* species – microscopic and molecular.

66   The microscopic methods such as Light microscopy, Giemsa and Toluidine staining, and

67   Transmission electron microscopy were introduced first (Fries et al., 2013); but they are still a

68   valuable, relatively cheap and simple method for screening and identification of *Nosema*

69   infection. According to Ptaszyńska et al. (2014), *N. ceranae* spores seem to be more sculptured

70   with deeper ornamentation than those of *N. apis*. Despite the fact that *N. apis* and *N. ceranae*

71   spores are morphologically different, in case of low rate of infection or presence of vegetative

72   forms of *Nosema,* differentiation between spores of *N. apis* and *N. ceranae* is very difficult This

73 requires the search for methods that are more sensitive. Therefore, various molecular methods

74 have been developed. Those include mainly PCR techniques (conventional or duplex PCR, PCR-

75 RFLP, qPCR) (Fries et al., 2013) involving usually a wide range of species-specific PCR primers

76 (Martín-Hernández et al., 2007; Klee et al. 2007; Chen et al. 2008).

77   Until now, there has been no data regarding the distribution of *N. apis* and *N. ceranae*

78 throughout Bulgaria as well as information if *N. ceranae* has become a dominant species,

79 although Nosema infection for the surrounding Balkan countries is well studied (Stevanovic et

80 al., 2010; Whitaker et al., 2010; Hatjina et al., 2011).

81   The main goal of the current study is to investigate and determine the presence and

82 distribution of the two different *Nosema* spp. in the Bulgarian honey bee.

83 **Materials and Methods**

84   **Sample collection**. A total of 108 honey bee samples were collected from three different parts

85 in the country: Rousse district (North Bulgaria, N=44), Sofia district (West Bulgaria, N=28) and

86 Smolyan district (South Bulgaria, N=36), (Table 1, Fig. 1) in April-May 2017. There is no bias

87 concerning the obtained honey bee samples. The first two regions are characterized by their low-

88 lying and generally flat plains, while the last region is situated in the Rodopa Mountains.

89 Sampling was done according to the guidelines of the Office International des Epizooties (2008).

90 None of the honey bee colonies were treated against *Nosema* infection for at least 6 months. In

91 each hive, five adult worker honey bees were randomly selected at the entrance of the hive or on

92 frames away from the brood nest. The honey bees were placed in a falcon tube, put in a cooler

93 bag and stored at – 20 °C prior to analysis.

94   **DNA extraction**. Briefly, prior to DNA extraction, the abdomen of a single bee was cut off

95 with scissors, mechanically homogenized with a cell lysis buffer and centrifuged for 1 min at 15

96 000 rpm. Total DNA was isolated by using GeneMATRIX Tissue and Bacterial DNA purification

97 Kit (Cat. No. E3551-01, EURx Ltd., Poland) according to the manufacturer instructions. Shortly,

98 the pellet was resuspended in a cell lysis buffer (a component of a DNA purification kit);

99 proteinase K was added and incubated overnight at 56 °C. The extracted DNA was resuspended

100 in 50 µL of elution buffer. The DNA concentration was determined spectrophotometrically and

101 the quality of the DNA samples was examined on 1% agarose gel electrophoresis stained with

102 Greensafe premium (Cat. No. MB13201, Nzytech, Portugal). The purified DNA was stored at –

103 20 °C until PCR assay.

104 **Gene selection and PCR amplification**. The small subunit (16S) ribosomal RNA gene was

105 chosen for molecular identification of *Nosema ceranae* and *Nosema apis*. A fragment of this gene

106 was amplified in both *Nosema* species using primers designed by Martín-Hernández et al. (2007).

107 321APIS-FOR (5'-GGGGGCATGTCTTTGACGTACTATGTA-3'; 321APIS - REV (5'-

108 GGGGGGCGTTTAAAATGGAAACAACTATG-3') for Nosema apis and 218MITOC - FOR

109 (5'-CGGCGACGATGTGATATGAAAATATTAA-3'); 218MITOC - REV (5'-

110 CCCGGTCATTCTCAAACAAAAACCG- 3') for *N. ceranae*.

111 Both primer sets were used together for performing a duplex PCR for identification and

112 discrimination of *Nosema* species.

113 The expected number of the amplified products in *N. ceranae* using the 218MITOC primers

114 can be either 218 or 219 depending on the sequences for *N. cerana*e available in the GenBank

115 database (http://www.ncbi.nlm.nih.gov/) (Martín-Hernández et al., 2007). In the case of *N. apis*,

116 the expected size of the amplicon using the 321APIS primers was 321 bp. In addition, a negative

117 control was included for all PCR reactions. As a positive control, cytochrome c-oxidase gene

118 (*CoI*2) of *Apis mellifera* was used in all studied samples. The sequence of primers used for

119 positive control was CoI2-F (5'-CCTGATATAGCATTTCCTCG-3') and CoI2-R (5'-

120 TGTGAATGATCTAAAGGTGG-3') designed on the base of the known mitochondrial genome

121 of *A. m. ligustica* (Acc. No. L06178, Crozier and Crozier, 1993). The PCR mixtures contained 25

122 µL of NZYTaq 2× Colourless Master Mix (Cat. No. MB04002, Nzytech, Portugal), 0.4 µM of

123 each species-specific primer (FOR/REV), 1 µL of template DNA and PCR water (Cat. No.

124 E0211-01, EURx Ltd., Poland) in a total volume of 50 µL. All PCR reactions were carried out

125 using a Little Genius thermocycler (BIOER Technology Co., Ltd) under the following conditions:

126 initial denaturation at 94 ºC for 5 min; 30 cycles (denaturation at 94 ºC for 30 s; primer annealing

127 at 50 ºC for 30 s; extension at 72 ºC for 1 min) and final extension at 72 ºC for 10 min. PCR

128 products were visualized on a 2 % agarose gel with Greensafe premium (Cat. No. MB13201,

129 Nzytech, Portugal). The fragment size was determined using Gene-Ruler™ 100 bp Ladder Plus

130 (Cat. No. SM0323, ThermoFisher Scientific Inc.).

131 **Sequence analysis**

132 The successfully amplified products for *Nosema* (20 samples) were purified by a PCR

133 purification kit (Gene Matrix, PCR clean-up kit, EURx, Poland) and sequenced in both directions

134 by a PlateSeq kit (Eurofins Genomics Ebersberg, Germany). The obtained sequences were

135 deposited in GenBank under accession no.: MG657260.

136 **Results**

137 Duplex PCR with species-specific primers (321APIS-FOR/REV and 218MITOC-FOR/REV)

138 produced PCR products in 57 samples out of 108 analyzed (52.8% successful amplifications),

139 while 51 samples failed to produce a PCR product (47.2%). There were no PCR products in the

140 negative controls. The results from the obtained sequences support identity only to *Nosema*

141 *ceranae* species.

142 From all investigated samples only *Nosema ceranae* infection was detected. The highest level

143 of infection was observed in North Bulgaria. From all 44 investigated samples, 34 (77.2%) were

144 *Nosema* positive (Table 1). In the west part of the country (Sofia district), *Nosema* positive

145 samples were detected in 18 from all 28 studied samples (64.3%). The lowest level of infections

146 was found in the honey bee samples from the mountainous part of the country (Smolyan district,

147   the Rodopa Mountains). From all 36 investigated samples, only 5 (13.9%) were *Nosema* positive.

148   Surprisingly, in all the studied samples from three different regions of the country only *Nosema*

149   *ceranae* was found. The presence of *Nosema apis* as well as co-infections *N. apis/N. ceranae*

150   were not detected (Table 1). Moreover, the honey bee samples from the flat part of the country

151   (Sofia and Rousse districts) had a higher prevalence of *N. ceranae* infection as compared with

152   samples obtained from the mountainous part (Smolyan district).

153   **Discussion**

154   In the current study, we have presented for the first time molecular identification of two

155   *Nosema* spp. and their distribution in Bulgaria. The results indicate the presence of *N. ceranae* in

156   57 of 108 investigated samples, which suggests the dominance of *N. ceranae* in all investigated

157   regions. The results of many studies from the Balkan countries have indicated that *N. ceranae*

158   displaces *N. apis* (Stevanovic et al., 2010; Whitaker et al., 2010; Hatjina et al., 2011; Gajger et

159   al., 2010) (Fig. 1). One reasonable question is why this introduced parasite (*N. ceranae*) has become

160   in a short time the dominant species worldwide? Concerning the virulence of the two *Nosema* spp.,

161   the results are contradictory. It is an interesting fact that in many European countries numerous

162   studies report that *N. ceranae* is more virulent and thus possesses a competitive advantage in

163   compared to *N. apis* (Klee et al., 2007; Paxton et al., 2007; Forsgren and Fries, 2010). Contrary to

164   this, more recent research, performed mainly in the USA, does not support these observations (Huang

165   et al., 2015; Milbrath et al., 2015). These studies suggest that the US honey bees may be less

166   susceptible to *N. ceranae* infections than European bees or that the US isolates of the pathogen are

167   less infective and less virulent than European isolates.

168   These findings are a suitable way to explain our results. We found that *N. ceranae* infection

169   prevailed in honey bee colonies from the flat part of the country (Rousse and Sofia district), while in

170   the mountainous part (Smolyan district, the Rodopa Mountains) the prevalence was the lowest (Table

171   1). Different subspecies of *Apis mellifera* are raised in the flat and in mountainous regions. *A. m.*

172   *macedonica* is considered to be a native honey bee for Bulgaria (Ruttner, 1988). More than three

173   decades ago, *A. m. ligustica*, *A. m. carnica* and *A. m. caucasica* were introduced and were reared in

174   Bulgaria (Bouga et al., 2011). These subspecies are disseminated mainly in the flat regions of the

175   country. On the other hand, in Bulgaria exists a local honey bee subspecies called *A. m. rodopica*,

176   geographically distributed only in the Rodopa Mountains massive (Petrov, 1995; Bouga et al., 2011;

177   Ivanova et al., 2012; Nikolova and Ivanova, 2012). Our previous investigation on mitochondrial

178   heredity have revealed that *A. m. rodopica* is a distinct subspecies concerning malfunction of COI

179   protein in compared to other honey bee subspecies reread in Bulgaria (Radoslavov et al., 2017).

180   According to Petrov (2010), *A. m. rodopica* possesses a lot of advantages in compared to the

181   introduced subspecies – good adaptation to the specific local climatic conditions, resistance numerous

182   diseases etc. These findings might explain the differences in the prevalence of *N. ceranae* in the

183   different areas since different subspecies of bees are reared in each area. Another fact, which may

184   explain the low rate of infection of *A. m. rodopica*, is the long geographical isolation of this

185   subspecies. Moreover, the beekeepers in this region are encouraged to raise this local honey bee and

186   even not to allow genetic introgression with other subspecies in Bulgaria.

187   Another fact which may explain the high rate of infestation with *N. ceranae* in honey bee colonies

188   from the plain regions in compared to the mountainous regions of the country is the different climatic

189   conditions in these places. The Rodopa Mountains climate is rather colder than the other two

190   investigated regions. This determine the later development of honey bee colonies (May-August).

191   Moreover, malfunction of COI protein in *A. m. rodopica* may associated with lower mitochondrial

192   respiration metabolism, which may determinate and lower activity of honey bees. Many papers have

193   discussed that warmer climatic conditions favored prevalence of *N. ceranae* (Tapaszty et al., 2009;

194   Stevanovic et al., 2011), whereas *N. apis* remains more prevalent in colder climates (Budge et al.,

195   2010; Gisder et al., 2010; Natsopoulou et al., 2015).

196   **Conclusion**

197   This is the first report of the distribution of *N. ceranae* of honey bee colonies in Bulgaria. We

198   found that *N. ceranae* is the dominant species in the Bulgarian honey bee. A local honey bee *A. m.*

199   *rodopica* reared in the Rodopa Mountains seems to be more resistant in compared to the introduced

200   species. Because of this, local honey bees should be kept as a part of the genetic diversity and the

201   related conservation activities.

Distribution of N. ceranae in three different regions in Bulgaria.

1   **Table 1**. Distribution of *N. ceranae* in three different regions in Bulgaria.

Region	No. of collected samples	No. of *Nosema* positive samples	% of *Nosema* positive samples	*N. ceranae*	*N. apis*	Co-infection
Smolyan (SB)	36	5	13.9	5	-	-
Sofia (WB)	28	18	64.3	18	-	-
Russe (NB)	44	34	77.2	34	-	-
Total	**108**	**57**	**52.8**	**57**	-	-

3   **Abbreviations**: SB – South Bulgaria; WB – West Bulgaria; NB – North Bulgaria

Figure 1

Map showing sampling locations in Bulgaria.

Nosema species distribution are represented in all Balkan countries.
