Objectives: We aimed to evaluate the global scientific output of gene research of myocardial infarction and explore their hotspots and frontiers from 2001 to 2015, using bibliometric methods. **Methods:** Articles about the gene research of myocardial infarction between 2001 and 2015 were retrieved from the Web of Science Core Collection (WoSCC). We used the bibliometric method and Citespace V to analyze publication years, journals, countries, institutions, research areas, authors, research hotspots, and trends. We plotted the reference co-citation network, and we used key words to analyze the research hotspots and trends. **Results:** We identified 1853 publications on gene research of myocardial research from 2001 to 2015, and the annual publication number increased with time. Circulation published the highest number of articles. United States ranked highest in the countries with most publications, and the leading institute was Harvard University. Relevant publications were mainly in the field of Cardiovascular system cardiology. Keywords and references analysis indicated that gene expression, microRNA and young women were the research hotspots, whereas stem cell, chemokine, inflammation and cardiac repair were the frontiers. **Conclusions:** We depicted gene research of myocardial infarction overall by bibliometric analysis. Mesenchymal stem cells Therapy, MSCs-derived microRNA and genetic modified MSCs are the latest research frontiers. Related studies may pioneer the future direction of this filed in next few years. Further studies are needed.

Running head: Bibliometric Analysis about MI Genetics Research

23

24 **Abstract**

25 **Background:** We aimed to evaluate the global scientific output of gene research of myocardial
26 infarction and explore their hotspots and frontiers from 2001 to 2015, using bibliometric methods.

27 **Methods:** Articles about the gene research of myocardial infarction between 2001 and 2015 were
28 retrieved from the Web of Science Core Collection (WoSCC). We used the bibliometric method
29 and Citespace V to analyze publication years, journals, countries, institutions, research areas,
30 authors, research hotspots, and trends. We plotted the reference co-citation network, and we used
31 key words to analyze the research hotspots and trends.

32 **Results:** We identified 1853 publications on gene research of myocardial research from 2001 to
33 2015, and the annual publication number increased with time. Circulation published the highest
34 number of articles. United States ranked highest in the countries with most publications, and the
35 leading institute was Harvard University. Relevant publications were mainly in the field of
36 Cardiovascular system cardiology. Keywords and references analysis indicated that gene
37 expression, microRNA and young women were the research hotspots, whereas stem cell,
38 chemokine, inflammation and cardiac repair were the frontiers.

39 **Conclusions:** We depicted gene research of myocardial infarction overall by bibliometric analysis.
40 Mesenchymal stem cells Therapy, MSCs-derived microRNA and genetic modified MSCs are the
41 latest research frontiers. Related studies may pioneer the future direction of this filed in next few
42 years. Further studies are needed.

43

44

45 **Introduction**

46 Myocardial infarction (MI), a life-threatening condition, occurs when lack of blood flow,
 47 causing the irreversible death of heart muscle. The incidence of MI has significantly increased in
 48 the past few decades, and MI remains a leading cause of death worldwide. With the development
 49 of genetic technology, gene researches have widely launched in MI. Researchers explore the
 50 genetics about MI and apply gene therapy for better treatment efficacy. Many genes have been
 51 identified an association with MI, such as PCSK9, TCF21(Braitsch et al. 2013; Kathiresan &
 52 Myocardial Infarction Genetics 2008). Genome-wide association studies also have found 27
 53 genetic variants that are associated with an increasing risk of MI(O'Donnell & Nabel 2011).
 54 Although numerous papers focused on gene research of MI, there are limited attempts to analyze
 55 them systematically.

56 There are several bibliometric studies focused on cardiovascular diseases research. Mark et al
 57 performed a global bibliometric analysis from 1999 to 2008 to evaluate trends disaggregated by
 58 country(Huffman et al. 2013). Publications has increased substantially in the past decade, but the
 59 low-income countries with higher disease burdens still had a lower output. Bloomfield and Al-
 60 Kindi confirmed this phenomenon separately by the bibliometric analysis from 52 African
 61 countries and the Middle East(Al-Kindi et al. 2015; Bloomfield et al. 2015). Shuaib and et al.
 62 focused on the citation frequency of top 100 cited cardiovascular articles(Shuaib et al. 2015).
 63 However, a global bibliometric analysis of the gene research of MI has not yet been performed.
 64 Bibliometric analysis is a widely used quantitative method to examine the knowledge structure
 65 and development in research fields(Guler et al. 2016). CiteSpace V is one of bibliometric

visualization tools for visualizing and analyzing emerging trends and transition patterns in scientific literature, which is developed by Chaomei Chen in 2004(Chen 2004; Chen 2006; Chen et al. 2010; Synnestvedt et al. 2005). Now it has been widely used to evaluate the productivity of institutions, countries and authors; identify international collaborations and geographic distributions; and explore research hotspots and frontiers in specified fields(Chen et al. 2014). In the present study, we performed a bibliometric analysis of articles on the gene research of MI indexed from 2001 to 2015, by using CiteSpace V to explore the research trend and hot spots.

Materials & Methods

We performed online retrieval from the Web of Science Core Collection (WoSCC) of Thomson Reuters on Oct 1, 2016. We used the key words “myocardial infarction” and “gene” to retrieve research articles or reviews between 2001 and 2015. We collected the following basic info for each article: authors, title, abstract, institution, country/region, journal, keywords, and references. The search queries were listed below in Supplementary Table 1.

Articles or reviews that meet the following criteria were included: (1) The time span is between 2001 and 2015. (2) Articles indexed in WoSCC. (3) Articles on gene research of MI, including original research and reviews. (4) Articles with basic info. The following document were excluded: (1) Meeting abstracts, proceedings, corrected articles, and repeated articles. (2) Unpublished Documents without enough information for further analysis.

The downloaded data were analyzed based on Web of Science database literature analysis report and export information function. Then we used CiteSpace V (64 bits) to analyze publication outputs and construct knowledge maps. In addition, we also used software VOSviewer (version

1.6.6) for better network visualizations in some cases(Ozsoy & Demir 2017; van Eck & Waltman 2010). In this paper, Individual network was derived from the 50 most cited articles published in a one-year time slice. TFIDF weighting was used to analyze the content of each cluster(Merigo & Montserrat 2010). Finally, we also applied burst detection to investigate the growth rate of citations or keywords(Lee et al. 2016).

Results

Based on the selection criteria, 1,853 publications about gene research of MI were indexed in WOSCC from 2001 to 2015, and were included in the study. Much of publications were research articles (1799, 97.1%), followed by review articles (54, 2.9%). English (98.4%) is primary language used by scholars, while the remaining 1.6% of the publications were written in Russian, Spanish, German and Portuguese. The number of publications (Supplementary Table 2) showed a gradually increased trend over time which rose from 82 in 2001 to 164 in 2015 and peaked in 2015.

More than 494 scholarly journals have published articles on MI research. The 10 most active journals are presented in Supplementary Table 3. They published 444 articles and accounted for 24.0% of all articles included in this study. Circulation published the highest number of articles (66, 3.616%), followed by Atherosclerosis (60, 3.238%), Plos One (48, 2.590%), American Journal of Physiology Heart and Circulatory Physiology and Journal of Molecular (42, 2.267%) and Cellular Cardiology (42, 2.267%).

The 1,853 articles originated from 69 countries and territories (Table 1, Figure 1). The top 10 countries are composed of six European countries, two Asian countries and two North American

countries which accounted for 94.87% of the total number of publications. USA, China, Japan, Germany and Italy were the most productive countries.

The 1,853 articles were published by more than 500 research institutions (Table 1, Figure 2). The top 10 institutions with the greatest outputs in this area totally published 351 articles, accounting for 18.94% of publications. The first major research echelon was led by Harvard University, followed by Karolinska Institutet, University of Washington, University of Toronto, and Leiden University.

Gene research of MI were distributed in more than 60 special research areas. Supplementary Table 4 shows the top 10 research areas from 2001 to 2015. Cardiovascular System Cardiology accounted for the largest number of publications (45.278%), followed by research experimental medicine (11.387%), genetics heredity (10.362%), cell biology (9.498%), and hematology (8.852%).

The 1853 articles were written by more than 11225 authors. The top 10 authors publishing articles were listed in Supplementary Table 5. Hamsten Anders from Karolinska Institutet, Psaty BM and Schunkert H published the most articles (25 records) and accounted for 1.349 % of all published articles. We also analyzed author citations, by using Citespace V, and constructed co-citation maps to evaluate the scientific relevance of publications. As shown in Figure 3, the largest nodes were Pfeffer MA (179 citations), Ridker PM (143 citations), Frangogiannis NG (125 citations) and Libby P (119 citations), indicating their important role in MI research. Additionally, there were 7 large citation clusters in Figure 3.

In the present study, we used CiteSpace V to construct a knowledge map of keyword co-occurrence with 147 nodes and 947 links (Figure 4) and identified the top 20 keywords in

publications from 2001 to 2015 (Supplementary Table 6), according to frequency and citation counts. The top keywords were ‘myocardial infarction’, ‘coronary artery disease’, ‘heart failure’, ‘expression’, ‘polymorphism’, ‘atherosclerosis’, and ‘gene expression’.

We used CiteSpace V to detect burst keywords. Burst keywords are considered as indicators of research frontiers or emerging trends over time. Figure 5 shows the top 20 keywords with the strongest citation bursts. The strongest ones include cytokine, angiotensin converting enzyme, genetics, mutation and mesenchymal stem cell. The recent burst of keywords were microRNA, mesenchymal stem cell, oxidative stress and gene therapy.

We constructed a co-cited reference map and explored changes associated with the key clusters of articles. The network contains 491 nodes and 1374 links. The Modularity Q was 0.7863 and the Mean Silhouette was 0.3218 (Figure 6). There were initially 71 clusters, and we filtered out small clusters with low silhouette. To learn more about the development of a cluster in a certain period, we also construct a reference co-citation time-view map (Figure 7). According to the citation frequency and centrality, we selected hotspot references in each period of time.

Discussion

When considered with the impact of a journal, we found that the top 10 active journals all had an IF >3.0, and more than 33.3% (3/10) of the top 10 active journals had an IF >10 which account for 7% of the total number of included publications, including Circulation (IF₂₀₁₅=17.047), Journal of the American College of Cardiology (IF₂₀₁₅=17.759) and Circulation Research (IF₂₀₁₅=11.551). When compared with the high-IF rate of all MI articles (7.5%), gene research of MI was still intensively published in high-IF journals.

The United States was the leading country in gene research of MI over the past 15 years, and China was the only developing country in the leading group, demonstrating its significant progress in the life sciences during the past 15 years. Our study is not the first investigation showing the pioneer countries in scientific output. These results were roughly consistent with previous cardiovascular disease bibliometric studies(Huffman et al. 2013). A 2017 study showed that the USA has the highest number of strong citation links with other countries, and China has highest growth(Gal et al. 2017). Although the number of publications from Latin America, Africa, and the Middle East increased in the past decade, these low- and middle-income countries with higher disease burdens still lag behinds developed countries, which are needed more target research investments and international collaboration(Al-Kindi et al. 2015; Bloomfield et al. 2015; Colantonio et al. 2015; Jahangir et al. 2011).

In Figure 3, the color of nodes indicated how new the associated reference was. Cool colors referred to old researches, warm colors new researches(Chen et al. 2012). Consequently, Ridker PM (in the bottom) and Pfeffer MA (in the top) represents the basis of MI research. The former concentrates on clinical associations, such as hyperhomocysteinemia, atherosclerosis and so on(Libby et al. 2011; Zee et al. 2007). The latter hammers focus on the pathophysiology, such as changes of the renal function(Verma et al. 2007). In the middle of Figure 3, warm-color nodes and linkages, leaded by Frangogiannis NG and Libby P, indicated that transcriptome was new directions(Fiedler et al. 2011; Ounzain et al. 2015). Young women label appeared twice in warm-color clusters, contacting closely with genotype, which may have indicated young MI women may be associated with genetics variants. Some articles found that young women with acute myocardial infarction have more comorbidity and higher in-hospital mortality than young men(Gupta et al. 2014). Young women with MI more often have a family history of premature MI, which was

addressed in a study of 398 families in which 62 vascular biology genes were evaluated. Single nucleotide polymorphisms in several thrombospondin genes were significantly associated with familial premature MI(Topol et al. 2001).

The topics involved in gene research of MI can be delineated in the keywords assigned to each article. Keywords provide a reasonable description of research hotspots, whereas burst words represent new research frontiers(Chen et al. 2014). Adjacent keywords are often assigned to the same articles. For example, in Supplementary Table 6, ‘coronary artery disease’, ‘atherosclerosis’, ‘myocardial infarction’, and ‘heart failure’ are closely related to coronary artery disease, and are different pathophysiology stages of CHD. Gene expression is the synthesis process of gene product which leads to the appearance in the phenotype. There are many gene products being associated with MI, such as microRNA, SDF1 and so on(Boon & Dimmeler 2015; Bromage et al. 2014). Burst words can be detected by CiteSpace, which represent words that are cited frequently in a period of time. As shown in Figure 5, the top 4 burst keywords were as follow, mesenchymal stem cell, oxidative stress, injury, and microRNA. Combined with those keywords with red lines in Figure 4 for further analysis, mesenchymal stem cells (MSCs) transplantation, microRNA and cardiac repair are forefronts of research in recent years. MSCs is a kind of non-hematopoietic stem cell with low immunogenicity, which has become the main cell for MI regenerative therapy(Chou et al. 2014). Many studies showed that MSCs transplantation therapy could have infarct-limiting and cardiac repair effects after MI by revitalizing the cardiac stem cell and revascularization(Russo et al. 2014; Shafei et al. 2017). Paracrine effect of MSCs could be mediated by extracellular vesicles, such as MSCs-derived exosomal microRNA(Huang et al. 2015; Wen et al. 2012). Genetic modified MSCs has been a therapeutic hotspot target for MI, which can promote secretion of paracrine factors to enhance the therapeutic effect(Karpov et al. 2017).

As is shown in Figure 6 and Supplementary Table 7, Cluster 0, 1, 4, and 5 play an important role. Cluster 0 (basic-fibroblast growth factor | gene expression profiles) was the largest while Cluster 1 (system biology / cell survival) and Cluster 4 (inflammation / young women) have the most burst cited-articles. The nodes and linkages of Cluster 2 (Chemokine / atherogenesis) and Cluster 5 (cardiac repair) are painted on warm color, and indicated they are the latest research, which is better visualized in Figure 7. Besides the same warm colors, Cluster 2 and Cluster 5 have related overlapping each other, indicating relevance from aspect of literature metrology. Upregulation of chemokines is a hallmark of the inflammatory following MI(Cavalera & Frangogiannis 2014). Some researchers have suggested that chemokines may be potential therapeutic targets to promote wholesome cardiac repair in MI patients(Cavalera & Frangogiannis 2014). It just so happens that “young women” appear once again in the Cluster 4 echoing with the previous keywords analysis, hint a hotspot in the gene research of MI(Spatz et al. 2015).

There are some limitations in our bibliometric study. The primary source of input data for CiteSpace is the WoSCC, which is more advanced at getting detailed data (e.g. journal sources, author, country and institution information). So, our analysis was performed only with publications in the WoSCC without using multiple search engines (Pubmed, Ovid, Scopus And Google Scholar et al. are not included). In addition, a linguistic bias may exist because most publications in the WoSCC were in English.

Conclusions

In summary, we depicted the scientific output of gene research of myocardial infarction by bibliometric analysis overall. Mesenchymal stem cells Therapy, MSCs-derived microRNA and

genetic modified MSCs are the latest research frontiers. Related studies may pioneer the future direction of this field in next few years. Further studies are needed.

Figure 1

Map of countries and territories of groups that published articles on the gene research of myocardial infarction during 2001-2015.

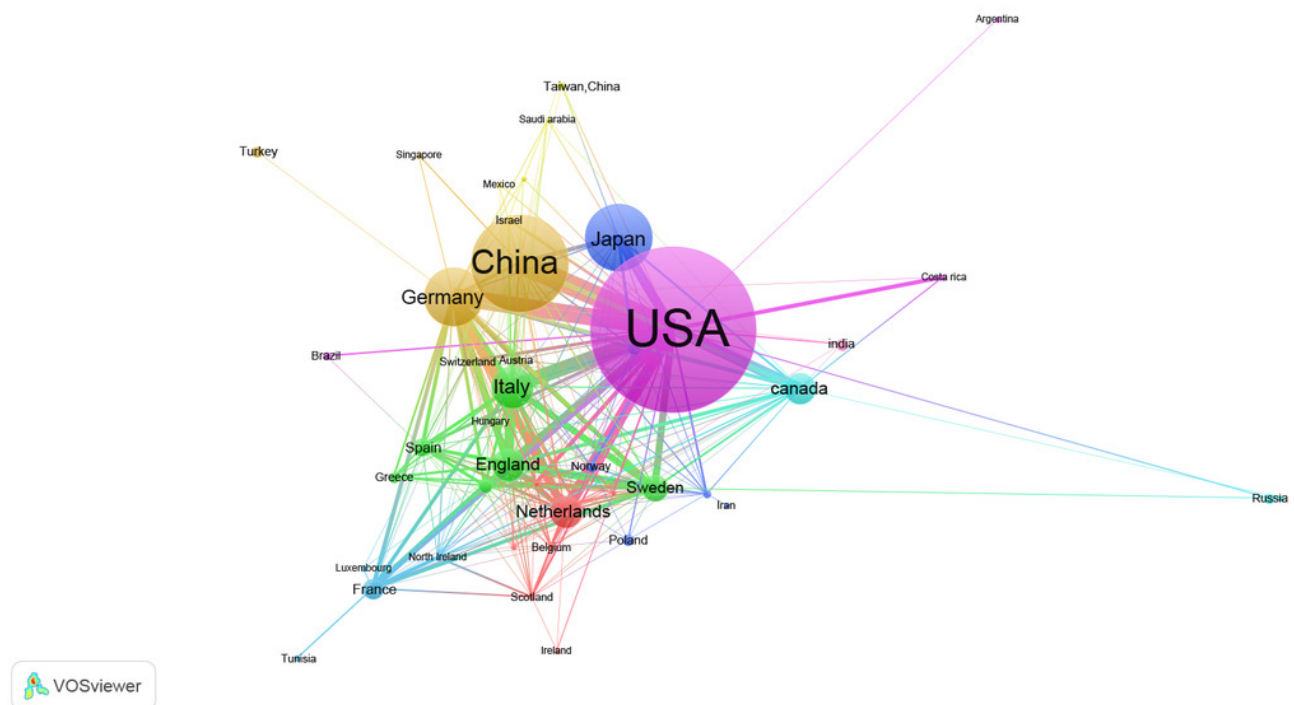

Figure 2

Institutions that published articles on the gene research of myocardial infarction during 2001-2015.

Figure 3

Co-citation map of authors who published articles on the gene research of myocardial infarction during 2001–2015

Keywords networks based on articles on the gene research of myocardial infarction during 2001-2015

Figure 5

Top 20 keywords with the strongest citation bursts on the gene research of myocardial infarction during 2001–2015

Top 20 Keywords with the Strongest Citation Bursts

Keywords	Year	Strength	Begin	End	2001-2015
cytokine	2001	13.4142	2002	2006	
angiotensin converting enzyme	2001	13.0615	2001	2006	
genetics	2001	11.665	2006	2009	
mutation	2001	10.4072	2001	2004	
mesenchymal stem cell	2001	9.8746	2011	2015	
injury	2001	9.8208	2012	2015	
endothelial growth factor	2001	9.7786	2008	2010	
oxidative stress	2001	9.5117	2012	2015	
microRNA	2001	9.1851	2013	2015	
haplotype	2001	9.0539	2006	2009	
congestive heart failure	2001	9.0239	2003	2005	
stem cell	2001	8.908	2010	2012	
cardiac function	2001	8.888	2010	2015	
rat	2001	8.3051	2001	2005	
infarction	2001	8.1902	2001	2005	
remodeling	2001	8.1658	2005	2007	
gene therapy	2001	7.9672	2011	2013	
nitric oxide synthase	2001	7.6665	2006	2007	
gene	2001	7.5736	2001	2003	
angiotensin ii	2001	7.4706	2003	2005
