Background. Despite great progress in studies on *Wolbachia* infection in insects, the knowledge about its relations with beetle species, populations and individuals, and the effects of bacteria on these hosts is still unsatisfactory. In this review we summarize the current state of knowledge about *Wolbachia* occurrence and interactions with Coleopteran hosts. **Methods.** An intensive search of the available literature resulted in the selection of 86 publications that describe the relevant details about *Wolbachia* presence among beetles. These publications were then examined with respect to the distribution and taxonomy of infected hosts and diversity of *Wolbachia* found in beetles. Sequences of *Wolbachia* genes (*16S rDNA*, *ftsZ*) were used for the phylogenetic analyses. **Results.** The collected publications revealed that *Wolbachia* has been confirmed in 204 beetle species and that the estimated average prevalence of this bacteria across beetle species is 38.3% and varies greatly across families and genera (0-88% infected members) and is much lower (c. 13%) in geographic studies. The majority of the examined and infected beetles were from Europe and East Asia. The most intensively studied have been two groups of herbivorous beetles: Curculionidae and Chrysomelidae. Coleoptera harbor *Wolbachia* belonging to three supergroups: F found in only 3 species, and A and B found in similar numbers of beetles (including some doubly infected); however the latter two were most prevalent in different families. 59% of species with precise data were found to be totally infected. Single infections were found in 69% of species and others were doubly- or multiply-infected. *Wolbachia* caused numerous effects on its beetle hosts, including selective sweep with host mtDNA (found in 3% of species), cytoplasmic incompatibility (detected in c. 6% of beetles) and other effects related to reproduction or development (like male-killing, possible parthenogenesis or haplodiploidy induction, and egg development). Phylogenetic reconstructions for *Wolbachia* genes rejected cospeciation between these bacteria and Coleoptera, with minor exceptions found in some Hydraenidae, Curculionidae and Chrysomelidae. In contrast, horizontal transmission of

bacteria has been suspected or proven in numerous cases (e.g. among beetles sharing habitats and/or host plants). **Discussion.** The present knowledge about *Wolbachia* infection across beetle species and populations is very uneven. Even the basic data about infection status in species and frequency of infected species across genera and families is very superficial, as only c. 0.15% of all beetle species have been tested so far. Future studies on *Wolbachia* diversity in Coleoptera should still be based on the Multi-locus Sequence Typing system, and next-generation sequencing technologies will be important for uncovering *Wolbachia* relations with host evolution and ecology, as well as with other, co-occurring endosymbiotic bacteria.

8 **Abstract**

9 **Background.** Despite great progress in studies on *Wolbachia* infection in insects, the knowledge
10 about its relations with beetle species, populations and individuals, and the effects of bacteria on
11 these hosts is still unsatisfactory. In this review we summarize the current state of knowledge
12 about *Wolbachia* occurrence and interactions with Coleopteran hosts.

13 **Methods.** An intensive search of the available literature resulted in the selection of 86
14 publications that describe the relevant details about *Wolbachia* presence among beetles. These
15 publications were then examined with respect to the distribution and taxonomy of infected hosts
16 and diversity of *Wolbachia* found in beetles. Sequences of *Wolbachia* genes (*16S rDNA*, *ftsZ*)
17 were used for the phylogenetic analyses.

18 **Results.** The collected publications revealed that *Wolbachia* has been confirmed in 204 beetle
19 species and that the estimated average prevalence of this bacteria across beetle species is 38.3%
20 and varies greatly across families and genera (0-88% infected members) and is much lower (c.
21 13%) in geographic studies. The majority of the examined and infected beetles were from Europe
22 and East Asia. The most intensively studied have been two groups of herbivorous beetles:
23 Curculionidae and Chrysomelidae. Coleoptera harbor *Wolbachia* belonging to three supergroups:
24 F found in only 3 species, and A and B found in similar numbers of beetles (including some
25 doubly infected); however the latter two were most prevalent in different families. 59% of species
26 with precise data were found to be totally infected. Single infections were found in 69% of
27 species and others were doubly- or multiply-infected. *Wolbachia* caused numerous effects on its
28 beetle hosts, including selective sweep with host mtDNA (found in 3% of species), cytoplasmic
29 incompatibility (detected in c. 6% of beetles) and other effects related to reproduction or

30 development (like male-killing, possible parthenogenesis or haplodiploidy induction, and egg
31 development). Phylogenetic reconstructions for *Wolbachia* genes rejected cospeciation between
32 these bacteria and Coleoptera, with minor exceptions found in some Hydraenidae, Curculionidae
33 and Chrysomelidae. In contrast, horizontal transmission of bacteria has been suspected or proven
34 in numerous cases (e.g. among beetles sharing habitats and/or host plants).

35 **Discussion.** The present knowledge about *Wolbachia* infection across beetle species and
36 populations is very uneven. Even the basic data about infection status in species and frequency of
37 infected species across genera and families is very superficial, as only c. 0.15% of all beetle
38 species have been tested so far. Future studies on *Wolbachia* diversity in Coleoptera should still
39 be based on the Multi-locus Sequence Typing system, and next-generation sequencing
40 technologies will be important for uncovering *Wolbachia* relations with host evolution and
41 ecology, as well as with other, co-occurring endosymbiotic bacteria.

42 **Short title** *Wolbachia* among Coleoptera: a review

43 **Introduction**

44 The relations between the intracellular α -proteobacterium *Wolbachia pipientis* Hertig
45 1936 (hereafter *Wolbachia*) and its hosts from various groups of arthropods and nematodes have
46 been the object of much research and numerous publications (O'Neill et al., 1992; Werren et al.,
47 1995a; Weinert et al. 2015). The majority of these studies have focused on verifying
48 endosymbiotic bacteria occurrence and diversity in various hosts at different levels: i) among
49 selected species sharing a geographic area (e.g. O'Neill et al., 1992; Werren et al., 1995a, 2000),
50 ii) among species inhabiting the same environment or that are ecologically-associated (e.g.
51 Stahlhut et al., 2010), iii) among species from particular taxonomic groups (e.g. Czarnetzki et al.,
52 2004; Lachowska et al., 2010; Sontowski et al., 2015), and iv) within populations of selected taxa
53 (e.g. Stenberg et al., 2004; Mazur et al., 2016). Another branch of research on the relations
54 between *Wolbachia* and its hosts has focused on host species phylogenetics or population
55 genetics, which is in some cases related to population differentiation and speciation (e.g. Kubisz
56 et al., 2012; Montagna et al., 2014). In this research, *Wolbachia* is sometimes treated as an
57 additional “marker” – a source of genetic data about the eco-evolutionary relations of its hosts. A

58 third type of *Wolbachia* studies has concerned the direct or indirect effects of the infection on
59 host fitness, development or survival at the individual and population levels (e.g. Weeks 2002;
60 O'Neill 2007). Moreover, in a separate branch of research (or in conjunction with the
61 abovementioned types of studies), *Wolbachia* is often examined directly, mainly with respect to
62 strain diversity, distribution and relations with other strains or different co-existing bacteria
63 (Baldo et al., 2007). All these branches of research have substantially extended the knowledge
64 about the relations between the most widespread intracellular endosymbiont – *Wolbachia* and its
65 various hosts. Moreover, these studies have been expanded to encompass other bacteria with
66 similar biologies and effects on hosts (like *Cardinium*, *Spiroplasma*, *Rickettsia*) (Zchori-Fein &
67 Perlman 2004; Goto et al., 2006; Duron et al., 2008; Weinert et al. 2015); however, a great
68 majority of studies are still conducted on *Wolbachia* (Zug & Hammerstein, 2012). Recently, the
69 various *Wolbachia* supergroups have been proposed to belong to several “*Candidatus Wolbachia*”
70 species (Ramírez-Puebla et al., 2015); however, this approach has been criticized (Lindsey et al.,
71 2016). Due to the uncertain species status of the “*Candidatus Wolbachia*” and because all
72 previous studies considered these presumed different species as distant supergroups, in this
73 review we have followed the previous *Wolbachia* taxonomy.

74 In summary, *Wolbachia* has been detected in 10-70% of examined hosts (Hilgenboecker et
75 al., 2008; Zug & Hammerstein, 2012), depending on the geographical, ecological or taxonomical
76 association of the selected species. Moreover, more detailed studies, at the population level, have
77 shown that infection is not as straightforward as was assumed in the early stages of *Wolbachia*
78 research. More and more species have been found to be only partially infected, e.g. in only some
79 parts of their ranges or infection was associated with only some phylogenetic lineages (usually
80 correlated with the distribution of mitochondrial lineages) (Clark et al., 2001; Roehrdanz et al.,
81 2006). Furthermore, examples of multiply infected species and individuals have been reported,
82 which has important consequences for the understanding of some of the effects of *Wolbachia*
83 infection (Malloch et al., 2000; Gurfield, 2016). *Wolbachia* is known to have numerous effects on
84 its hosts, among which the most interesting and important are those that disturb host
85 reproduction, such as cytoplasmic incompatibility, thelytokous parthenogenesis, feminization of
86 genetic males, male-killing, increased mating success of infected males via sperm competition
87 and the host's complete dependence on bacteria for egg production (for reviews see Werren,
88 1997; Werren & O'Neill, 1997 and Stouthamer et al., 1999). Some of these effects are responsible
89 for diversification of host populations and consequently *Wolbachia* have probably been involved

90 in speciation (e.g. by the selective sweep of mtDNA or the whole genome of the infected host
91 with the genome of bacteria; Keller et al., 2004; Mazur et al., 2016). This could be another major
92 factor, additional to those already known, responsible for radiation of insects and particularly
93 beetles.

94 There are several reviews summarizing the state of knowledge on *Wolbachia* infection
95 among various taxonomic groups of nematodes and arthropods. Over the last years, such reviews
96 have been prepared for the following groups: filarial nematodes (Filarioidea) (Taylor & Hoerauf,
97 1999; Casiraghi et al., 2001), crustaceans (Crustacea) (Cordaux et al., 2001), spiders (Araneae)
98 (Goodacre et al., 2006; Yun et al., 2010), mites (Acari) (Chasirini et al., 2015), springtails
99 (Collembola) (Czarnetzki et al., 2004), Heteropteran Bugs (Heteroptera) (Kikuchi et al., 2003),
100 ants (Formicidae) (Russell, 2012), wasps (Hymenoptera: Apocrita) (Schoemaker et al., 2002) and
101 butterflies (Lepidoptera) (Tagami et al., 2004). Surprisingly, there is no such review for beetles
102 (Coleoptera), which include large number of diversified taxa, known from various habitats, and
103 whose members belong to all major trophic guilds of animals. Some groups of beetles have been
104 examined with respect to *Wolbachia* infection, but usually only with a limited coverage of species
105 (e.g. weevils, Curculionidae, Lachowska et al., 2010; leaf beetles; Chrysomelidae, Clark et
106 al., 2001, Jäckel et al., 2013; jewel beetles; Buprestidae, Sontowski et al., 2015 and minute moss
107 beetles, Hydraenidae, Sontowski et al., 2015).

108 In this review we have summarized the current state of knowledge on the relations
109 between beetles and *Wolbachia* by referring to all the abovementioned aspects of research.
110 Moreover, we have highlighted future research directions concerning *Wolbachia* relationships
111 with their diverse Coleopteran hosts.

112 **Survey Methodology**

113 We searched the scientific literature with Web of Knowledge databases, using the
114 following combination of keywords linked by AND (the Boolean search term to stipulate that the
115 record should contain this AND the next term): “*Wolbachia*” AND “Coleoptera” and
116 “*Wolbachia*” AND “beetles”. Our final literature search for this analysis was conducted on
117 December 22, 2017. This produced 322 results. Each result was inspected to determine whether
118 or not it contained information on the subject matter. Articles that had no relevance (e.g. any
119 reports that were not about *Wolbachia*-Coleoptera relations, including those that only had some
120 references to either beetles or bacteria in the citations) were excluded. After the removal of

121 duplicates, 65 were excluded from the remaining articles ($n = 234$) for not being direct reports
122 about *Wolbachia*-Coleoptera relations, 44 were excluded because they examined other hosts and
123 only referred to publications on Coleoptera, and 44 others were excluded because they referred to
124 data already presented in previous publications on Coleoptera. The use of two alternative and
125 comprehensive scientific collections should have reduced any biases. Each document was read
126 critically for the information that it contained on *Wolbachia*-Coleoptera relations, with special
127 reference to answering the study questions listed below. Figure 1 shows a flow diagram for the
128 systematic review following Prisma guidelines (Moher et al., 2009).

129 We examined the collected data on various aspects of *Wolbachia* infection in Coleoptera
130 with respect to the following: the i) characteristics of the publications (to determine the scope and
131 progress of studies on *Wolbachia*) ($n=86$), ii) geographic distribution of infected beetle species
132 and populations ($n=84$), iii) sampling design (how many sites and individuals were examined)
133 ($n=63$), iv) characteristics of the markers (genes) used for genotyping the bacteria ($n=82$) and
134 their hosts ($n=34$), v) numbers and frequencies of species found to be infected in particular beetle
135 families and genera ($n=58$), vi) supergroup prevalence in examined taxonomic groups ($n=43$),
136 vii) strain distribution and diversity in populations and individuals ($n=30$), viii) effects of
137 *Wolbachia* on its beetle hosts ($n=39$). Statistical analyses (Spearman correlation for number of
138 publication across years and for the number of examined and number of infected species, Chi²
139 test for frequency of supergroups and infected taxa in particular taxonomic groups, Chi² ANOVA
140 for comparison of single/double/multiple infected taxa, Kruskal-Wallis Z test for infection
141 frequency in Chrysomelidae and Curculionidae) were done in Statistica 11 (Statsoft).

142 Finally, we downloaded from GenBank (<https://www.ncbi.nlm.nih.gov/genbank/>) and the
143 *Wolbachia* MLST database (<https://pubmlst.org/wolbachia/>) all available sequences of *Wolbachia*
144 genes found in any species of beetle. We restricted further analyses to the most widely used
145 bacteria genes, i.e. *16S rDNA* and cell division protein gene *ftsZ*. Because of the different lengths
146 and spans of available sequences, the long parts of the 3' and 5' ends of each gene were trimmed,
147 which resulted in alignments of length 663 bp for *16S rDNA* and 241 bp for *ftsZ*. The length of
148 the *ftsZ* alignment was particularly short as two different sets of primers have been used for its
149 amplification, and its amplicons only overlapped across a relatively short part of the gene.
150 Phylogenetic trees were only reconstructed for unique gene variants found in particular host taxa.
151 Trees were inferred using Maximum Likelihood (ML) implemented in IQ-TREE web server
152 <http://www.iqtree.org/> (Trifinopoulos et al., 2016) under the following settings Auto selection of

153 substitution model, ultrafast bootstrap approximation (UFBoot) (Minh et al., 2013) with 10000
154 iterations, maximum correlation coefficient = 0.99, single branch test with use of the approximate
155 Likelihood-Ratio Test (SH-aLRT) (Anisimova & Gascuel, 2006; Guindon et al., 2010) and other
156 default options.

157 The nomenclature of host taxa and their systematic positions throughout the paper follow
158 the articles from which the data was derived.

159 **Characterization of *Wolbachia* infection among Coleoptera**

160 *Publications*

161 The final list of publications concerning data about *Wolbachia* infection in Coleoptera
162 comprised 86 papers (Supplementary Table 1). The oldest articles with relevant information about
163 *Wolbachia* infection in beetles were published in 1992 (Campbell et al., 1992; O'Neill et al.,
164 1992), and the number of articles since then has increased significantly year by year (Spearman
165 correlation = 0.841; Fig. 2). The majority of these articles (60%) concerned infection in only
166 single beetle species, whereas 19% discussed infection in multiple species belonging to the same
167 genus, 6% – multiple species from the same family, 6% – various species of Coleoptera et al.,
168 and a further 9% – studies on geographic groups of insects that included some, usually random
169 species of beetles (O'Neill et al., 1992; Werren et al., 1995, 2000; Weinert et al. 2015).

170 Most studies were done on Curculionidae (34) and Chrysomelidae (34), following
171 Tenebrionidae (9), Coccinellidae (10) and Sylvanidae (3) (Supplementary Table 1). The members
172 of all other families were investigated in only 1-2 studies. Consequently, 2.5 and 1.6
173 Curculionidae and Chrysomelidae species were respectively examined per article. All species of
174 Hydraenidae and Buprestidae were included in only single articles (Sontowski et al., 2015),
175 whereas limited numbers of species of Coccinellidae and Tenebrionidae were examined in several
176 articles (Hurst et al., 1999; Fialho & Stevens 1996, 1997, 2000; Majerus et al., 2000; et al.,
177 Weinert et al., 2007; Elnagdy et al., 2013; Ming et al., 2015; Goodacre et al., 2015; Kageyama et
178 al., 2015; Li et al., 2015; Li et al., 2016; Dudek et al., 2017). *Wolbachia* infection was only
179 studied more than once in 20 species.

180 *Sampling design*

181 The majority of species investigated with respect to *Wolbachia* infection were from
182 Europe, and a relatively high number of species were from Asia and both Americas, whereas only

183 ten infected species were from Africa, and three from Australia-Oceania (Fig. 3). A number of
184 publications describing *Wolbachia* infection in Coleoptera had similar geographic coverages (Fig.
185 3).

186 Studies were done on samples collected from an average of 5.2 sites and concerned on
187 average 53.0 specimens, or if excluding the most widely studied families Curculionidae and
188 Chrysomelidae, 6.0 sites and 65.1 individuals (Fig. 4). For Curculionidae and Chrysomelidae,
189 these numbers were on average 4.4 and 6.0 sites, respectively, and 40.7 and 70.2 individuals,
190 respectively (Fig. 4). The numbers of sites and individuals examined in particular groups were
191 insignificantly different, with the exception of the numbers of examined individuals in
192 Curculionidae and Chrysomelidae (Fig. 4).

193 *Examined genetic markers*

194 The most often used *Wolbachia* gene for studies on Coleoptera was *ftsZ*, followed by
195 *hcpA*, *wsp* and *16S rDNA* (Fig. 5). Most studies using *hcpA* also used other MLST genes,
196 including *ftsZ*. On the other hand, many species were only investigated with either *16S rDNA* or
197 *wsp* or *ftsZ* alone. Single studies used *groEL* (*Monochamus alternatus*, Aikawa et al., 2009;
198 *Tribolium madens*, Fialho & Stevens, 2000) or *ITS* genes (*Tribolium madens*, Fialho & Stevens,
199 2000). So far, only five studies have used next-generation sequencing technology (Illumina or
200 454) to detect *Wolbachia*; two used *16S rDNA* for metabarcoding of microbiota (*Sitona obsoletus*,
201 *Steriphus variabilis*, White et al., 2015; *Aleochara bilineata* and *Aleochara bipustulata*, Bili et al.,
202 2016; *Hylobius abietis*, Berasategui et al., 2016; *Brontispa longissimi*, Takano et al., 2017;
203 *Harmonia axyridis*, Dudek et al., 2017) and one used shotgun genomic sequencing (*Amara*
204 *alpine*, Heintzman et al., 2014). For genotyping of hosts, 52.4% of studies utilized fragments of
205 *COI* from mtDNA (usually a barcode fragment of this gene). Fewer studies (23.1%) analyzed
206 *rDNA* (usually *ITS1* and/or *ITS2* spacers), *EF1 α* (14.0%), *Wingless* (2.2%), *Histone H3* (2.2%)
207 and microsatellites (6.1%). In *Wolbachia*-related studies, host genes have been used for several
208 purposes like i) using host DNA as a control for genetic material quality, ii) barcoding for host
209 species identification, iii) phylogenetics, phylogeography and population genetics, iv) estimating
210 co-evolutionary relations between the bacteria and host, and v) detecting some of the effects of
211 *Wolbachia* on its hosts (like linkage disequilibrium, selective sweep, cytoplasmic
212 incompatibility).

213 *Taxonomic coverage*

214 The beetles examined with respect to *Wolbachia* infection belong to 23 families
215 (Micromalthidae, Gyrinidae, Haliplidae, Noteridae, Dytiscidae, Carabidae, Staphyllinidae,
216 Hydrophilidae, Hydraenidae, Anobiidae, Dermestidae, Buprestidae, Byturidae, Cleridae,
217 Lampyridae, Coccinellidae, Tenebrionidae, Scarabeidae, Meloidae, Sylvanidae, Cerambycidae,
218 Chrysomelidae, Curculionidae). In total 204 beetle species were found to harbor *Wolbachia*
219 infection; however, the distribution of infected species among families varied markedly. The
220 highest numbers of infected beetle species were found for the Curculionidae (81 species),
221 Chrysomelidae (49 species), Hydraenidae (14 species), Buprestidae (13 species), Coccinellidae
222 (12 species) and Dytiscidae (8 species) (Fig. 6). In all other families only 1-3 species were
223 reported to harbor *Wolbachia* (Supplementary Table 1). However, these numbers are biased by
224 the low number of articles (studies) dealing with members of particular beetle families (see
225 above).

226 Considering infection across beetle genera, the most richly infected genera were *Altica*
227 (Chrysomelidae, 17 species), *Naupactus* (Curculionidae, 11 species), *Hydraena* (Hydraenidae, 8
228 species) and *Agrius* (Buprestidae, 6 species) (Supplementary Table 1). In total, 49 genera were
229 found to have infected members (Supplementary Table 1, Table 1). The infection in Coleoptera
230 was estimated at 38.3% of examined species; however, the proportion of infected species varied
231 greatly between families and genera. At the family level the infection frequency was from 10.5%
232 (Tenebrionidae) to 100% (Noteridae) (Goodacre et al., 2015, Sontowski et al., 2015); however
233 when considering only families for which more than 30 species were investigated (e.g. Clark et
234 al., 2001; Lachowska-Cierlik et al.; 2010, Rodriguer et al.; 2010a, Kondo et al.; 2011, Jäckel et
235 al., 2013; Sontowski et al.; 2015, Kawasaki et al., 2016), infection was found in up to 63% of
236 species (Hydraenidae) (Table 1). At lower taxonomic levels, *Wolbachia* was found in 25% of
237 Diabroticite (Chrysomelidae; Clark et al., 2001), 14.3-16.7% of Bruchina (Chrysomelidae;
238 Kondo et al., 2011), 34.8% of Scolytinae (Curculionidae, Kawasaki et al., 2016) and 16.7% of
239 Curculioninii (Toju et al., 2013). Among 54 genera in which *Wolbachia* infection was examined
240 for at least 2 species, 12 genera were completely uninfected, while 6 genera were completely
241 infected (Table 1). If considering only genera with at least 5 verified species, *Wolbachia* was
242 found in 0% (*Acmaeodera*; Buprestidae; Sontowski et al., 2015) to 88% of species (*Altica*,
243 Chrysomelidae; Jäckel et al., 2013). There was only a marginally negative and insignificant
244 correlation between the number of examined and number of infected species ($R=-0.078$). If
245 considering only the most widely examined families, Chrysomelidae and Curculionidae, the

246 difference in infection frequency between these two groups was insignificant ($Z=-1.656$,
247 $P=0.098$). Geographic studies on *Wolbachia* prevalence in insects have found much lower
248 frequencies of infection in Coleoptera species: the bacterium was found in only 10.5% of beetles
249 from Panama and 13.5% of beetles from North America (Werren et al., 1995a, 2000).

250 *Wolbachia* diversity

251 Among the various beetle species, *Wolbachia* strains belonged to three supergroups (A, B
252 and F). However, they occurred at very different proportions in different groups of beetles, and
253 these differences were significant ($\text{Chi}^2=98.78$, $P=0.000$). Overall, the proportion of beetle
254 species found to be infected with *Wolbachia* strains belonging to supergroups A or B was similar,
255 with approx. 12% of all species harboring either supergroup (either as single infections in
256 different species or populations or as multiple infections within individuals) (Fig. 7), whereas
257 supergroup F was found in only 3 beetle species: *Agrius araxenus* and *Lamprodila mirifica* (both
258 Buprestidae; Sontowski et al., 2015) and *Rhinocyllus conicus* (Curculionidae; Campbell et al.,
259 1992). In the four groups of beetles with the highest numbers of examined and infected species,
260 the distributions of supergroups varied: in Buprestidae, a similar numbers of species were
261 infected by supergroups A and B (all singly infected), with a relatively high proportion of F
262 infected species (Sontowski et al., 2015). In contrast, in Hydraenida, supergroup A dominated
263 over supergroup B (Sontowski et al., 2015). This was also the case in Chrysomelidae, with some
264 species infected by both strains (Kondo et al., 2011.; Jäckel et al., 2013; Kolasa et al., 2017). The
265 most varied infections were observed in Curculionidae, with supergroup B dominating, a
266 presence of taxa infected by both A and B supergroups, and a single species infected by F
267 supergroup (Lachowska-Cierlik et al.; 2010, Rodriguer et al., 2010a; Kawasaki et al., 2016) (Fig.
268 7). Considering the frequency of infected specimens in the examined beetle species represented
269 by the available data ($N=106$), 63 species were reported to be totally infected (all individuals
270 possessed *Wolbachia*), whereas 43 species had this bacterium in only some individuals (if
271 exclude Chrysomelidae and Curculionidae: 8 and 15 species, respectively) (Fig. 8). The same
272 calculated for Chrysomelidae resulted in 17 and 10 species, respectively, and for Curculionidae in
273 38 and 18 species, respectively (Fig. 8). These differences between these values (between these
274 groups of species) were significant ($\text{Chi}^2=72.03$, $P=0.000$). A single *Wolbachia* strain was
275 observed in 43 species (species with available data $N = 62$), whereas two strains were reported in
276 10 species (*Byturus tomentosus*, Malloch et al., 2000; *Altica quercetorum*, Jäckel et al., 2013;
277 *Callosobruchus chinensis*, Okayama et al., 2016; *Chelymopha alternans*, Keller et al., 2004;

278 *Crioceris quaterdecimpunctata* and *Crioceris quinquepunctata*, Kolasa et al., 2017; *Adalia*
279 *bipunctata*, Majerus et al., 2000; *Polydrusus inustus*, Kajtoch et al., 2012; *Cyanapion afer* and *C.*
280 *spencii*, Kajtoch et al., 2017) and multiple infection in a further 9 species (*Callosobruchus*
281 *chinensis*, Kondo et al., 2002; *Diabrotica barberi*, Roehrdanz & Levine, 2007; *Conotrachelus*
282 *nenuphar*, Zhang et al., 2010; *Pityogenes chalcographus*, Arthofer et al., 2009; *Xyleborus dispar*
283 and *Xylosandrus germanus*, Kawasaki et al., 2016) (Fig. 8). In Chrysomelidae (N=22) these
284 numbers were 12, 5 and 5, respectively and in Curculionidae (N=37), 30, 3 and 4, respectively
285 (Fig. 8). The numbers of single, double and multiple infected individuals in these groups of
286 beetles differed insignificantly (Chi^2 ANOVA=2.364, P=0.307).

287 *Effects on hosts*

288 *Wolbachia* affected beetle hosts in several ways. Linkage disequilibrium and/or selective
289 sweep between bacteria and host genomes (usually with host mtDNA) were detected in 6 species
290 (3% or 9% if excluding Chrysomelidae and Curculionidae): 2 (4%) Chrysomelidae (*Altica lythri*,
291 Jäckel et al., 2013; *Apthona nigriscutis*, Roehrdanz et al., 2006) and 4 (5%) Curculionidae
292 (*Eusomus ovulum*, Mazur et al., 2016; *Naupactus cervinus*, Rodriguero et al., 2010b, *Polydrusus*
293 *inustus*, *Polydrusus pilifer*, Kajtoch et al., 2012). Cytoplasmic incompatibility was detected or
294 suspected but unconfirmed in 12 (6% or 18% if excluding Chrysomelidae and Curculionidae)
295 Coleoptera: 6 (13%) Chrysomelidae (*Chelymorpha alternans*, Keller et al., 2004, *Diabrotica*
296 *barberi*, Roehrdanz & Levine 2007, et al., *Diabrotica virgifera virgifera*, Giordano et al., 1997;
297 *Callosobruchus chinensis*, Kondo et al., 2002; *Callosobruchus analis*, Numajiri et al., 2017;
298 *Brontispa longissimi*, Takano et al., 2017), 3 (4 %) of Curculionidae (*Cossomus sp.*, Zhang et al.,
299 2010; *Hypothenemus hampei*, Mariño et al., 2017, *Xylosandrus germanus*, Kawasaki et al., 2016),
300 1 of Sylvanidae (*Oryzaephilus surinamensis*, Sharaf et al., 2010) and 1 of Tenebrionidae
301 (*Tribolium confusum*, Li et al., 2016, Ming et al., 2015). Horizontal transfer of *Wolbachia* was
302 detected or suspected in 26 species of Coleoptera (13% or 39% if excluding Chrysomelidae and
303 Curculionidae) – 16 (33%) species of Chrysomelidae (several species of *Altica*, Jäckel et al.,
304 2013, *Crioceris quaterdecimpunctata* and *Crioceris quinquepunctata*, Kolasa et al., 2017) and 10
305 (14%) species of Curculionidae (members of *Euwallacea*, *Xyleborus*, *Xylosandrus*, *Xyleborinus*
306 *schaufussi* and *Taphrorychus bicolor*, Kawasaki et al., 2016, *Polydrusus* and *Parafoucartia*
307 *squamulata*, Kajtoch et al., 2012; *Sitophilus oryzae* and *S. zaemais*, Carvalho et al., 2014). Other
308 effects of *Wolbachia* on beetles included the following: i) transfer of bacteria genes to the
309 autosomes of the host (so far detected only for *Monochamus alternatus*, Cerambycidae, Aikawa

310 et al., 2009 and *Callosobruchus chinensis*, Chrysomelidae, Nikoh et al., 2008); ii) coexistence of
311 *Wolbachia* with *Rickettsia* (*Calvia quattuordecimguttata*, *Coccidula rufa*, *Coccinella*
312 *septempunctata*, *Halyzia sedecimguttata*, *Rhizobius litura*, Weinert et al., 2007; *Sitona obsoletus*,
313 White et al., 2015; *Micromalthus debilis*, Perotti et al., 2016) in the host or with *Spiroplasma*
314 (*Chilocorus bipustulatus*, Weinert et al., 2007; *Aleochara bipustulata*, Bili et al., 2016) or with
315 both (*Adalia bipunctata*, Majerus et al., 2000, *Harmonia axyridis*, Dudek et al., 2017; *Curculio*
316 *sikkimensis*, Toju & Fukatsu, 2011; *Aleochara bilineata*, Bili et al., 2016); iii) induction and
317 reinforcement of parthenogenesis, however this effect had weak support and had other possible
318 alternative explanations (numerous species of Naupactini, Rodriguer et al., 2010a and *Eusomus*
319 *ovulum*, Mazur et al., 2016; all Curculionidae; *Micromalthus debilis*, Perotti et al., 2016); iv)
320 possible induction of haplodiploidy (*Euwallacea interjectus*, *Euwallacea validus*, Curculionidae,
321 Kawasaki et al., 2016); v) male-killing (*Tribolium madens*, Tenebrionidae, Fialho & Stevens,
322 2000); vi) necessity of infection for egg development (*Otiiorhynchus sulcatus*, Curculionidae, Son
323 et al., 2008; *Coccotrypes dactyliperda*, Zchori-Fein et al., 2006); vii) populations evolving
324 towards endosymbiont loss and repeated intraspecific horizontal transfer of *Wolbachia*
325 (*Pityogenes chalcographus*, Curculionidae, Arthofer et al., 2009), viii) fitness decline in infected
326 beetles (*Callosobruchus analis*, Numajiri et al., 2017), ix) modification of sperm (*Chelymopha*
327 *alternans*, Clark et al., 2008), x) down-regulation of defense genes in host plants (*Diabrotica*
328 *virgifera virgifera* on maize, Barr et al., 2010).

329 *Phylogenetic relations*

330 The tree reconstructed for *16S rDNA* included 52 sequences from bacteria found in 45
331 host beetle species. This tree included three major lineages, with separate clusters of *Wolbachia*
332 sequences belonging to A, B and F supergroups (Supplementary Fig. 1). F supergroup was
333 represented by a single sequence from *Rhinocyllus conicus* (Curculionidae) (Supplementary Fig.
334 1). Sequences assigned to supergroup A (based on information available in the articles) were
335 found to be polyphyletic. Some *16S* sequences from *Xylosandrus* spp. and *Curculio* spp.
336 (Curculionidae), or *Oreina cacaliae* and *Galeruca tanacetii* (Chrysomelidae) clustered as a sister
337 lineage to all other A and B sequences (Supplementary Fig. 1). Overall, the diversity of *16S*
338 sequences assigned to supergroup B was much greater than those assigned to supergroup A
339 (Supplementary Fig. 1).

340 The tree reconstructed for *ftsZ* included 131 sequences found in 114 host beetle species.
341 The *ftsZ* phylogenetic tree resulted in a topology similar to that of *16S rDNA* – it included groups
342 of sequences belonging to A, B and F supergroups (Supplementary Fig. 2). Supergroup F was
343 represented by *Agrilus araxenus* and *Sphaerobothris aghababiani* (both Buprestidae). Moreover,
344 the supergroup B clade was divided into two clusters, among which one included a small group
345 of sequences found in four beetle hosts: *Chelymorpha alternans* (Chrysomelidae), *Eurymetopus*
346 *fallax*, *Sitophilus oryzae* and *Conotrachelus nenuphar* (all three Curculionidae) (Supplementary
347 Fig. 2). Also in this gene, the genetic variation of sequences belonging to supergroup A was much
348 lower, and only a few sequences were highly diverged (e.g. strains of *Callosobruchus chinensis*,
349 Chrysomelidae; *Tribolium confusum*, Tenebrionidae or *Polydrosus pilosus*, Curculionidae)
350 (Supplementary Fig. 2). There was also one slightly distinct clade that mainly consisted of
351 bacteria sequences found in some Hydraenidae, Curculionidae and Chrysomelidae
352 (Supplementary Fig. 2).

353 The abovementioned phylogenetic reconstructions of the relations among *Wolbachia*
354 strains identified on the basis of polymorphism of several genes show that there is no strict
355 correlation between host phylogeny and bacterial strain relationships. Even in studies that
356 covered multiple related species (e.g. those belonging to the same genus), evidence for direct
357 inheritance of *Wolbachia* strains from common ancestors is restricted to Hydraenidae (Sontowski
358 et al., 2015) and some species of *Oreina* (Montagna et al., 2014) or *Curculio* (Toju et al., 2013).
359 In the case of *Altica*, the data show that cospeciation was rare and restricted to a few recently
360 diverged species (Jäckel et al., 2013). In contrast, there are numerous examples of
361 phylogenetically related beetle species possessing different *Wolbachia* strains (e.g. Lachowska et
362 al., 2010). It is also often the case among related species that some are infected, whereas others
363 not (*Crioceris*, Kubisz et al., 2012; *Oreina*, Montagna et al., 2014; *Cyanapion*, Kajtoch et al.,
364 2017); so any assumption that the bacteria were inherited from a common ancestor would also
365 need to consider multiple losses of infection. The latter phenomenon is probable; however, there
366 is no direct evidence from natural populations, at least in studies on beetles, of *Wolbachia*
367 disappearing over time. Some exemplary studies that found *Wolbachia* present in related species,
368 after detailed examination, rejected the idea that bacteria was inherited from a common ancestor.
369 This was because different host species harbored unrelated stains (e.g. among weevils,
370 Lachowska et al., 2010, Rodriguer et al., 2010a) or in cases where strains were identical or
371 similar, the hosts were not phylogenetically close to each other (e.g. *Crioceris*, Kubisz et al.,

372 2012). Finally, there is evermore proof of horizontal *Wolbachia* transmission via different
373 mechanisms, such as via predators, parasitoids, common habitat or foraging on the same host
374 plants (Huigens et al., 2004; Stahlhut et al., 2010; Caspi-Fluger et al., 2012; Ahmed et al., 2015;
375 Kolasa et al., 2017). Studies on beetles have mainly provided indirect evidence of such
376 transmissions. There are known groups of species that inhabit the same environments and share
377 the same or very similar *Wolbachia* strains, e.g. steppic weevils from East-central Europe (Mazur
378 et al., 2014) and bark beetles in Japan (Kawasaki et al., 2016). Recently, evidence for has also
379 appeared for the role of host plants in bacteria spread – *Wolbachia* DNA was detected in two
380 species of *Crioceris* leaf beetles and in their host plant – *Asparagus* spp. (Kolasa et al., 2017).

381 Finally, in light of the proposed “*Candidatus* *Wolbachia*” species, the summarized
382 phylogenetic relations among *Wolbachia* strains infecting various beetles indicate that the
383 taxonomic distinctiveness of supergroups is inconclusive (Ramírez-Puebla et al., 2015; Lindsey
384 et al., 2016). First, beetles generally harbor members of supergroups A and B, and only
385 occasionally members of supergroup F. Therefore, it is not possible to make any conclusions
386 about broader *Wolbachia* taxonomy based only on *Wolbachia* strains found in Coleoptera.
387 However, there are numerous examples of beetle hosts harboring both supergroups, including
388 beetles in which some *Wolbachia* genes are of supergroup A origin, while others are of
389 supergroup B origin; this indicates that recombination between strains belonging to different
390 supergroups is quite frequent. This is evidence against the designation of the “*Candidatus*
391 *Wolbachia*” species, at least with respect to members of supergroup A and B.

392 **Current gaps and future endeavors**

393 The present knowledge on *Wolbachia* infection across beetle species and populations is
394 very uneven. Even the basic data about infection statuses in species and frequencies of infected
395 species across genera and families is superficial, as there are only c. 200 beetle species known to
396 be infected. This means that if 38% is the average frequency of infection among beetle species,
397 then only c. 530 species have been tested so far. This is merely c. 0.15% of the total number of
398 beetles, which is estimated to be around 360 000 species (Farrell, 1998; Bouchard et al., 2009).
399 We know even less at the population level, as the majority of beetle species have only had single
400 individuals tested for *Wolbachia* infection (e.g. Lachowska et al., 2010, Sontowski et al., 2015).
401 These very basic screens have probably underestimated the number of infected species because of
402 false-negative results obtained for species with low or local infection in populations. There is also

403 another and important cause that should be mentioned - low titer infections that are under the
404 detection limit of conventional PCR (e.g., Arthofer et al., 2009; Schneider et al., 2013). On the
405 other hand, these preliminary estimates could have overestimated the real number infected
406 beetles, as sampling in these studies was rarely random and most often focused on specific
407 groups, e.g. on genera for which preliminary data suggested the presence of *Wolbachia* infection.
408 Indeed, an intensive search of *Wolbachia* infection across hundreds of beetle species from Europe
409 suggested a lower infection rate – c. 27% to be infected (Kajtoch et al., unpublished). Also,
410 knowledge about infection at the geographic scale is very uneven, and only Europe and Asia
411 (basically China and Japan) have been relatively well investigated. There is a huge gap in the
412 knowledge for African, Australian and Oceanian beetles, where a high diversity of beetles exists
413 and probably a similar diversity of *Wolbachia* could be expected (e.g. compared to preliminary
414 data available from Central and South America (Werren et al., 1995; Rodriguer et al., 2010a)).

415 Little is known about *Wolbachia* diversity in beetle hosts, as the majority of studies used
416 only single genetic markers, and often different genes were sequenced for different taxa. This
417 precludes complex analysis of *Wolbachia* diversity across all tested beetle hosts. This has
418 changed since 2006, since Baldo et al. (2006) proposed Multilocus Sequence Typing (MLST),
419 which is based on the genotyping of five housekeeping genes, usually in conjunction with *wsp*
420 sequencing. MLST is and should remain a sufficient way to understand basic *Wolbachia*
421 diversity. On the other hand, to fully understand *Wolbachia* relations among strains and
422 supergroups (or presumed species), between *Wolbachia* and its hosts and especially between
423 *Wolbachia* and other microorganisms, amplicon-sequencing (e.g. *16S* rDNA) or genome-
424 sequencing are needed. This could be achieved thanks to the development of next-generation
425 sequencing technologies (NGS). Surprisingly, despite fast development of NGS in the last years,
426 very few studies have used this technology for studying *Wolbachia* in beetle populations. For
427 example, five studies sequenced *16S* amplicons generated from microbiota and detected
428 *Wolbachia* (White et al., 2015; Bili et al., 2016; Berasategui et al., 2016; Takano et al., 2017;
429 Dudek et al., 2017). The only study that utilized shotgun sequencing was executed for other
430 purposes and only accidentally showed *Wolbachia* genes in examined species (Heintzman et al.,
431 2014). NGS is probably the best prospect for studies on *Wolbachia* infection and diversity, and
432 will help to answer most current riddles and issues.

433 The big challenge is to understand the impact of infection on beetle biology, physiology
434 and ecology. It is known that *Wolbachia* has several effects on host reproduction, but relatively

435 few studies prove or suggest e.g. cytoplasmic incompatibility, male-killing or other effects on the
436 development of selected beetles (Clark et al., 2001; Keller et al., 2004 Roehrdanz et al., 2006
437 Roehrdanz & Levine 2007 Sharaf et al., 2010 Zhang et al., 2010; Jäckel et al., 2013; Ming et al.,
438 2015; Kawasaki et al., 2016; Li et al., 2016; Mariño et al., 2017; Numajiri et al., 2017; Takano et
439 al., 2017). It is very probable that this bacteria has large and frequent effects on beetle
440 reproduction and is consequently partially responsible for beetle radiation, at least in some
441 taxonomic groups, geographic areas or habitats. Also very few studies have shown data on
442 linkage disequilibrium and selective sweep between bacterium and host genomes (Roehrdanz et
443 al., 2006; Rodriguero et al., 2010b; Kajtoch et al., 2012; Jäckel et al., 2013; Mazur et al., 2016).
444 These effects could also have probably been involved in speciation of numerous beetles.
445 Moreover, this phenomenon could have serious implications for beetle barcoding, as selective
446 sweep is known to reduce mitochondrial diversity in its hosts and therefore could decrease the
447 number of identified species (Hurst & Jiggins, 2005). On the other hand, cytoplasmic
448 incompatibility can lead to the origin of highly diverged phylogenetic mitochondrial lineages
449 within species, which would increase the number of identified taxa (Smith et al., 2012). Also
450 here, NGS technologies will enable more sophisticated analyses of these genetic relations and
451 their effects (e.g. by the sequencing of transcriptomes for physiological studies or by genotyping-
452 by-sequencing for phylogenetic studies). Genotyping with NGS should also verify whether the
453 recent assumption that different supergroups are indeed “*Candidatus Wolbachia*” species is
454 correct or not (Ramírez-Puebla et al., 2015; Lindsey et al., 2016).

455 Only very preliminary results suggest *Wolbachia* was not only transmitted vertically, but
456 that it could also have spread horizontally (Jäckel et al., 2013; Carvalho et al., 2014; Kawasaki et
457 al., 2016; Kolasa et al., 2017; Mazur et al., 2017). Horizontal transmission was considered as an
458 event that happens in evolutionary timescales. Only recently, Schuler et al. (2013) showed that
459 such a transfer can happen within a few years after arrival of a new strain. In light of the general
460 lack of cospeciation between bacteria and beetles, horizontal transmission must be a highly
461 underestimated phenomenon. Horizontal transmission of *Wolbachia* among beetles cannot be
462 confirmed without considering other coexisting insects that can mediate transmission, such as
463 predators, parasitoids or beetle prey. Moreover, other arthropods that share habitats with beetles,
464 e.g. phoretic ticks (Hartelt et al., 2004) and nematodes (Casiraghi et al., 2001), need to be
465 examined. Finally, host plants are promising objects of studies on *Wolbachia* transmission across
466 beetle populations (Kolasa et al., 2017), as phloem is probably an important mediator of this

467 bacteria's spread across insect populations (DeLay, 2012; Li et al., 2016). Concerning
468 transmission – another very interesting topic is the transfer of *Wolbachia* genes into host genomes
469 (Dunning Hotopp et al., 2007; Koutsovoulos et al., 2014; Funkhouser-Jones et al., 2015). This
470 issue has only been reported twice for beetle hosts so far (Nikoh et al., 2008; Aikawa et al.,
471 2009). This problem could be important as if such transfers are frequent, simple testing of
472 *Wolbachia* presence in a host based on single or even several gene sequencing could overestimate
473 the number of truly infected species, populations or individuals.

474 Finally, a very interesting topic for future studies is the examination of the presence of
475 other intracellular and symbiotic bacteria (like *Cardinium*, *Spiroplasma*, *Rickettsia*) in Coleoptera
476 and their relations, both with the host and *Wolbachia*. So far, only seven studies have found
477 *Wolbachia* with *Rickettsia* and/or *Spiroplasma* together in beetle hosts (Majerus et al., 2000;
478 Weinert et al., 2007; Toju & Fukatsu 2011; White et al., 2015; Perotti et al., 2016; Bili et al.,
479 2016; Dudek et al., 2017). Preliminary results suggest that there is some balance in the number of
480 these bacteria, probably caused by competition within host cells (Goto et al., 2006). A recent
481 summary of the presence of these bacteria in insects showed that *Rickettsia* has been found in
482 single species of Micromalthidae, Staphylinidae, Buprestidae, Coccinellidae and Curculionidae
483 (Werren et al., 1994; Lawson et al., 2001; Weinert et al., 2007; Toju & Fukatsu 2011; White et al.,
484 2015; Perotti et al., 2016; Bili et al., 2016), *Spiroplasma* in some species of Staphylinidae,
485 Coccinellidae and Curculionidae (Majerus et al., 1998; Hurst et al., 1999; Tinsley & Majerus,
486 2006; Weinert et al., 2007; Toju & Fukatsu 2011; Bili et al., 2016), and *Cardinium* has not been
487 detected so far in any beetle species (Zchori-Fein et al., 2004). The coexistence of different
488 endosymbiotic bacteria and their effects on hosts should also be investigated with NGS
489 technologies, which are able to detect bacteria in numerous hosts (e.g. individuals) at once and
490 estimate prevalence of bacteria in various hosts or different tissues. NGS has already been proven
491 to be a powerful tool for detecting undescribed bacteria (e.g. it allowed the identification of new
492 Alphaproteobacteria in *Brontispa longissimi*; Takano et al., 2017). Different endosymbiotic
493 bacteria could have either similar or contrasting effects on beetle species, populations and
494 individuals and could be the greatest overlooked phenomenon in the evolution and ecology of
495 Coleoptera.

496 In our opinion, beetles are still an insufficiently examined group of *Wolbachia* hosts,
497 especially considering their systematic and ecological diversity. All issues in studies on
498 *Wolbachia* in Coleoptera are generally the same as in other hosts of these bacteria, or *vice versa*;

499 there is no issue that has been or is being studied on *Wolbachia* infection in other (non-beetle)
500 hosts that could not also be examined in beetle hosts. And the extraordinary diversity of beetles
501 (with respect to their diverse systematics at various taxonomic levels, complex phylogenetic
502 relations and extensive ecological relations with each other and numerous other species) makes
503 this group an excellent target for *Wolbachia* studies. The presented summary about *Wolbachia*
504 infection in beetles shows that despite numerous studies, there are still many issues that need to
505 be investigated. We hope that this systematic review will facilitate various future studies on
506 *Wolbachia* infection among beetles.

507 Acknowledgements

508 We kindly thank Prof. Lech Borowiec for providing the pictures of beetles from his
509 ICONOGRAPHIA COLEOPTERORUM POLONIAE (© Copyright by Prof. Lech Borowiec,
510 Wrocław 2007–2014, Department of Biodiversity and Evolutionary Taxonomy, University of
511 Wrocław, Poland)], which were used for preparation of the graphics. We are grateful to
512 anonymous Reviewers for all their comments and suggestions, which allowed for a great
513 improvement of the manuscript.

Figure 1

Prisma flow-diagram (see Moher et al., 2009) for literature on *Wolbachia*-Coleoptera relations included in this study.

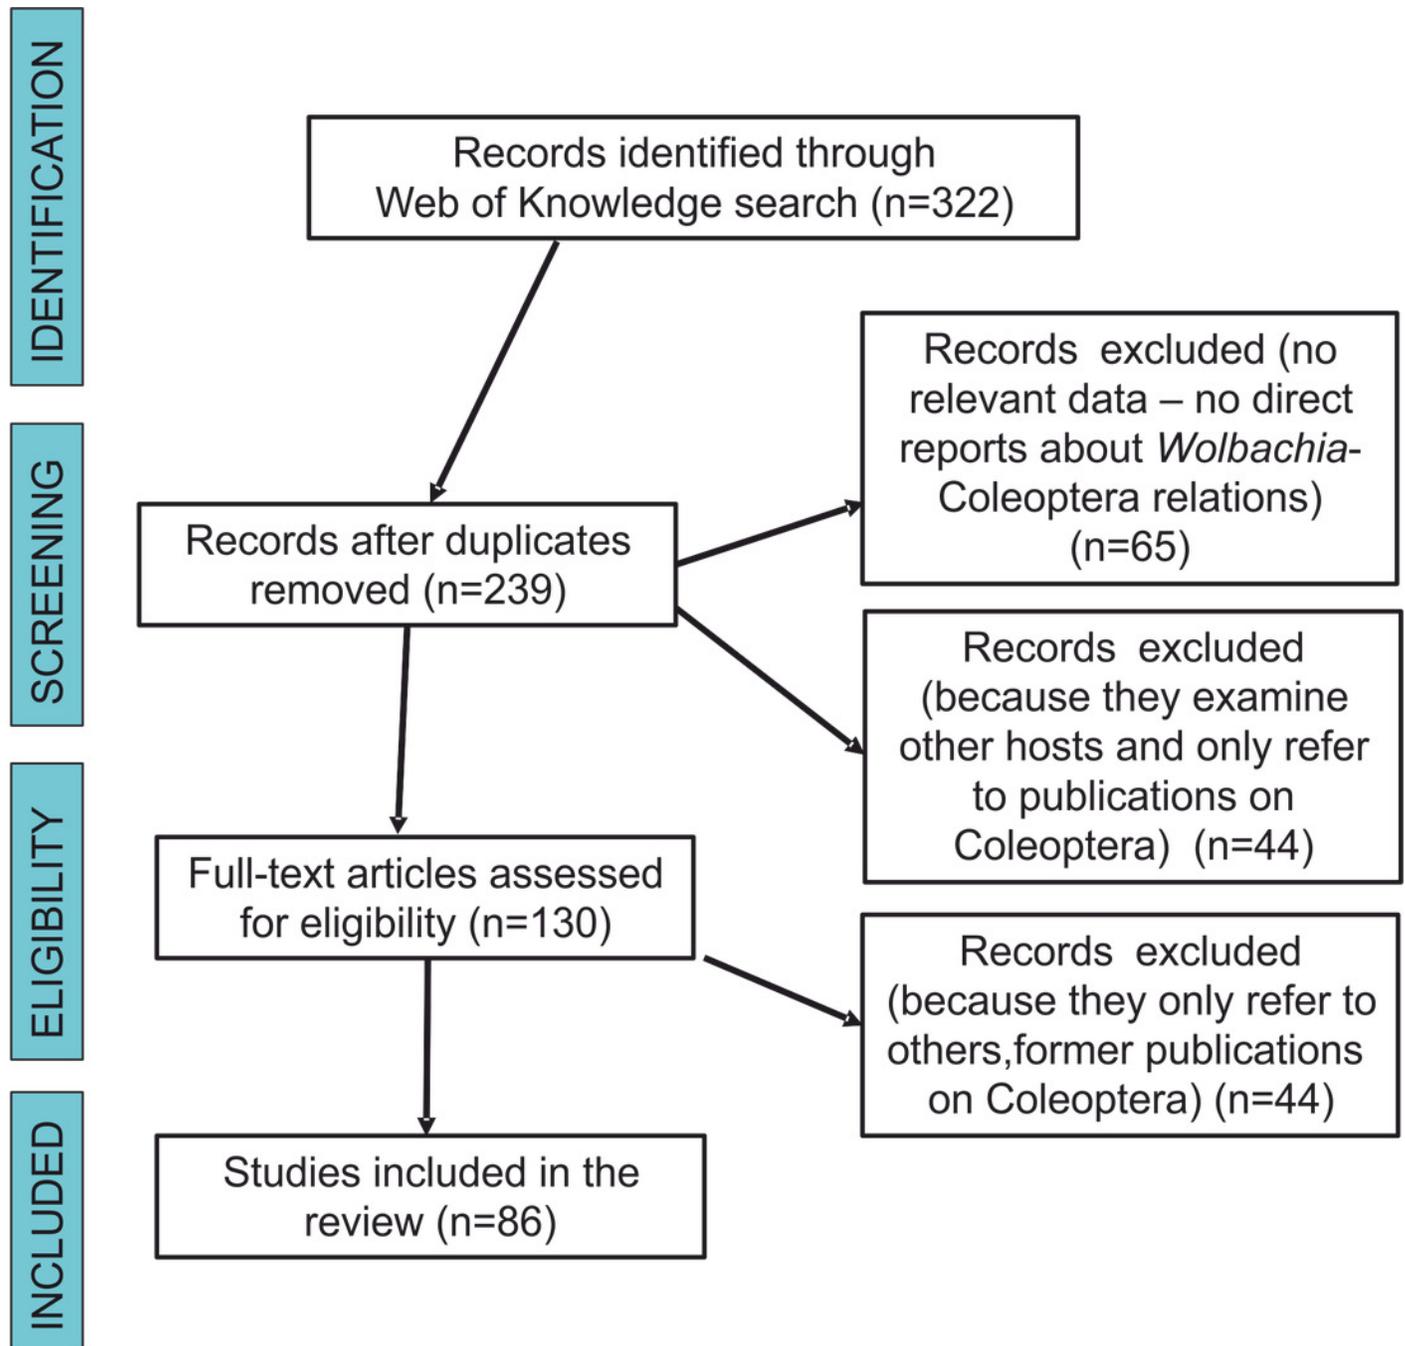

Figure 2

Change in the number of publications considering *Wolbachia* infection among Coleoptera.

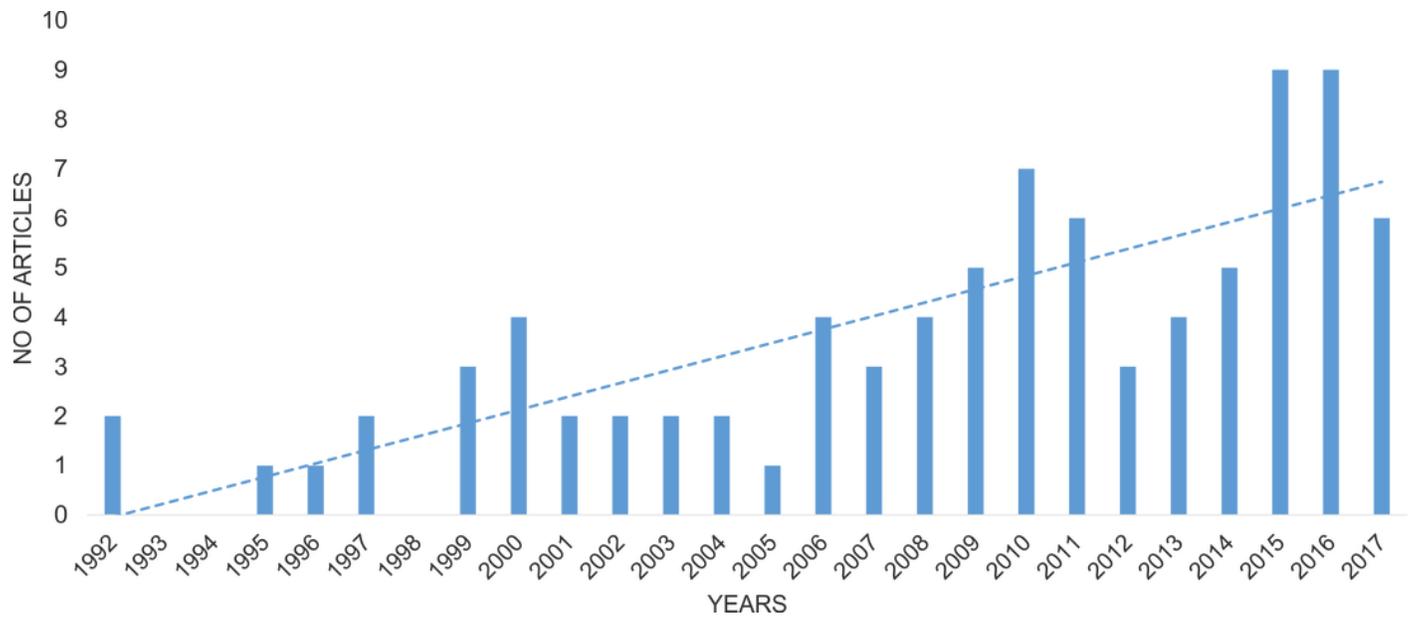

Figure 3

Number of publications that described *Wolbachia* infection among Coleoptera and number of infected beetle species.

Both are shown with respect to the zoogeography of the examined hosts (from which continent the host was collected).

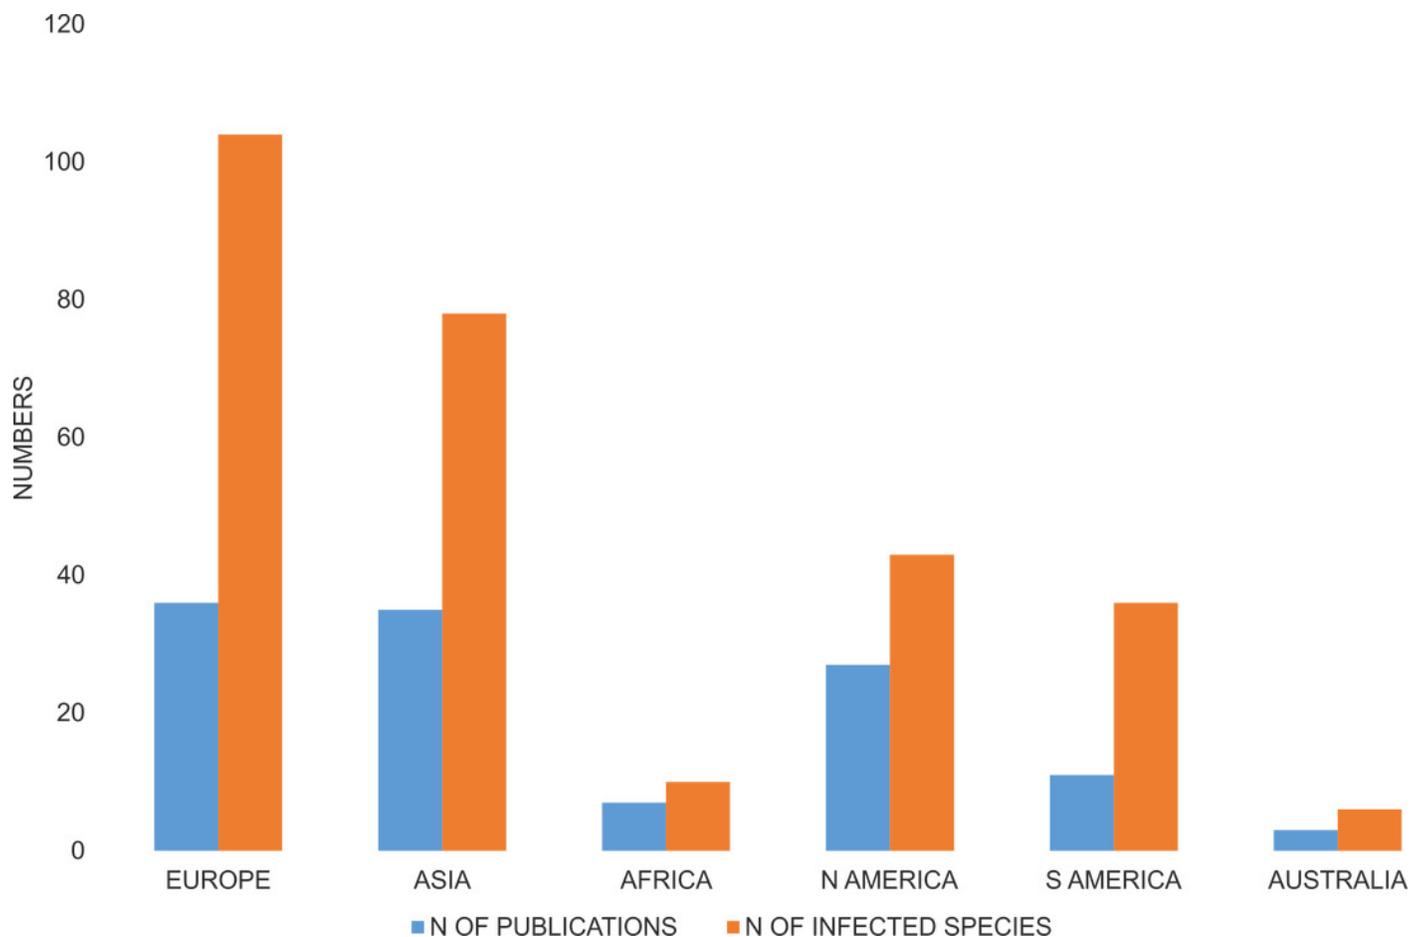

Figure 4

Number of sites (A) and number of individuals (B) of beetles examined with respect to *Wolbachia* infection.

P - Mann-Whitney test p-values.

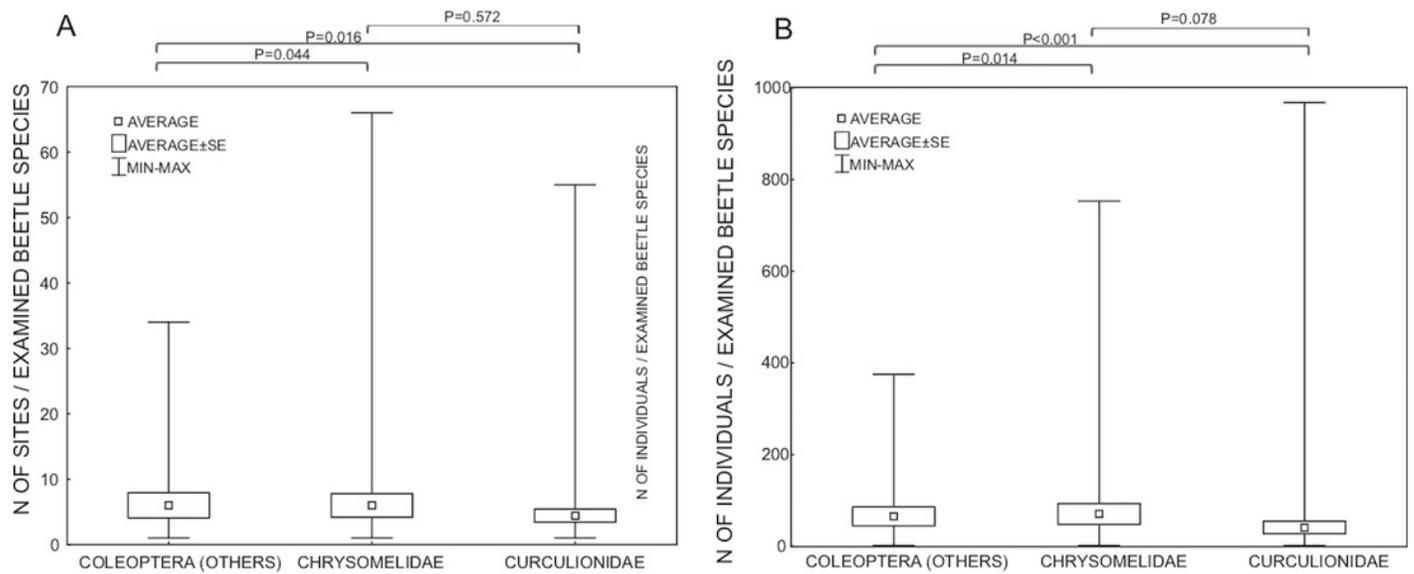

Figure 5

Shares of *Wolbachia* genes used in studies on *Wolbachia* infection among Coleoptera.

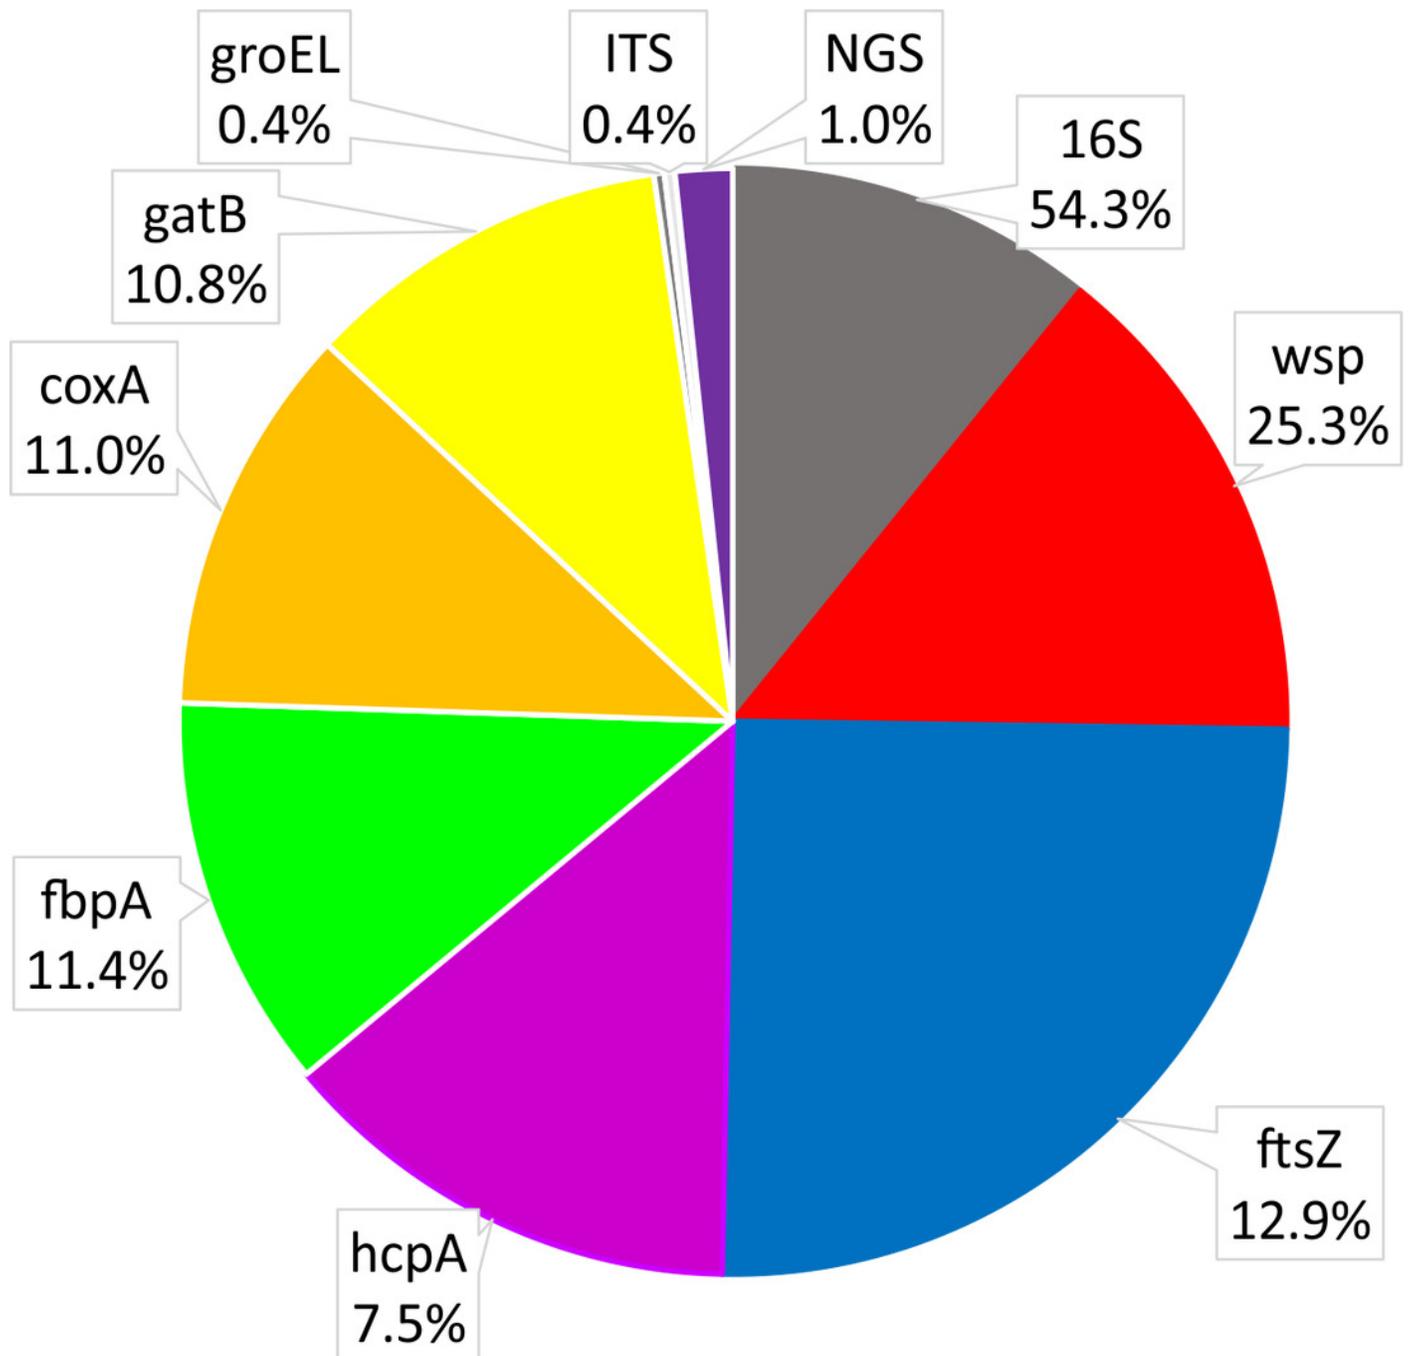

Figure 6

Shares of *Wolbachia* infected beetle species across the examined families of Coleoptera.

The numbers presented after the family names indicate the number of infected species.

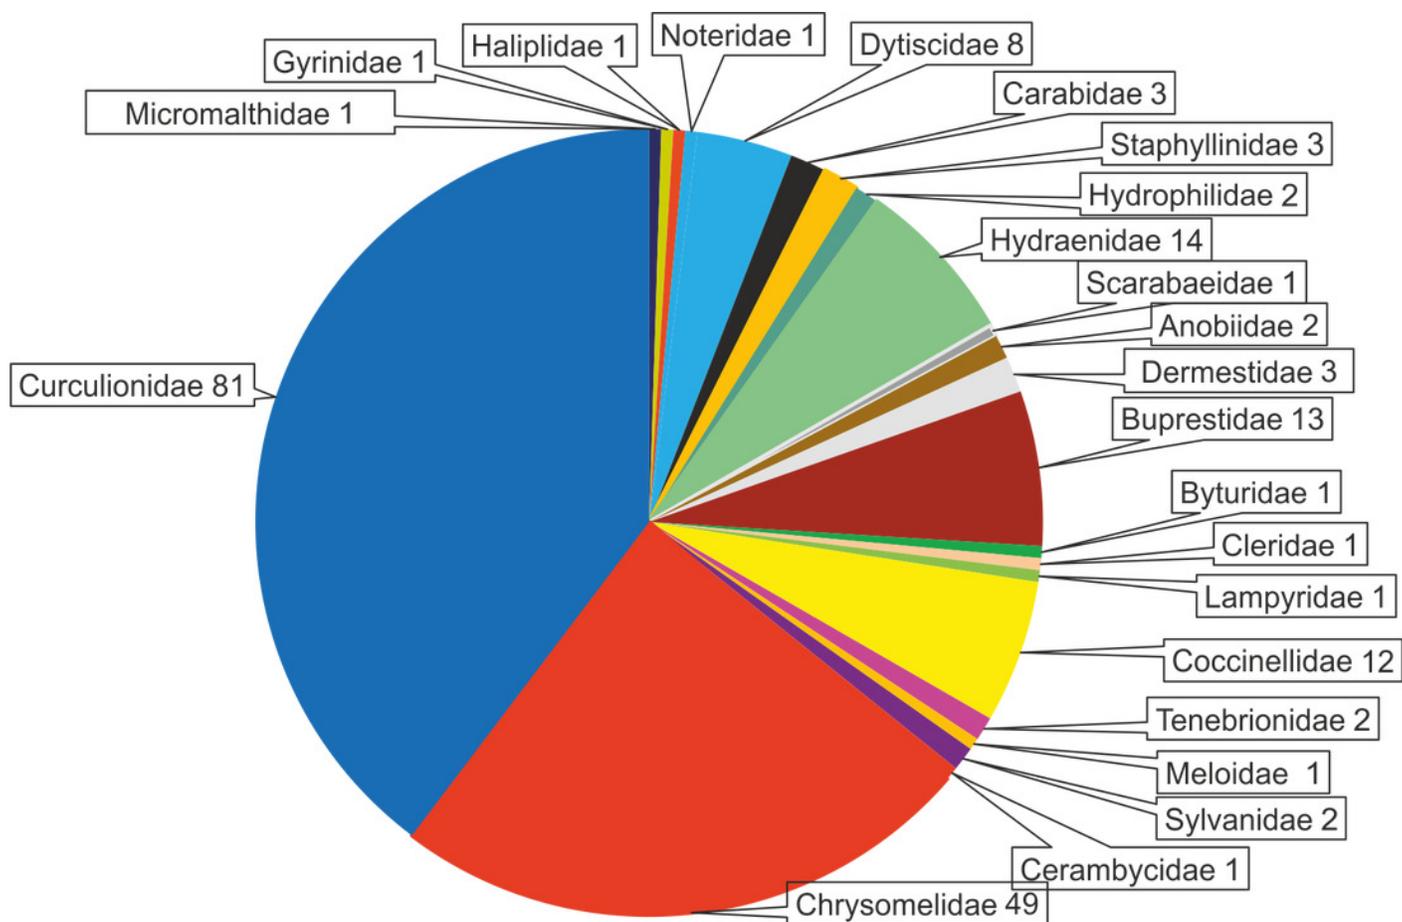

Figure 7

Shares of beetles infected by *Wolbachia* supergroups (A, B, F).

[Beetle photographs are from ICONOGRAPHIA COLEOPTERORUM POLONIAE (© Copyright by Prof. Lech Borowiec).

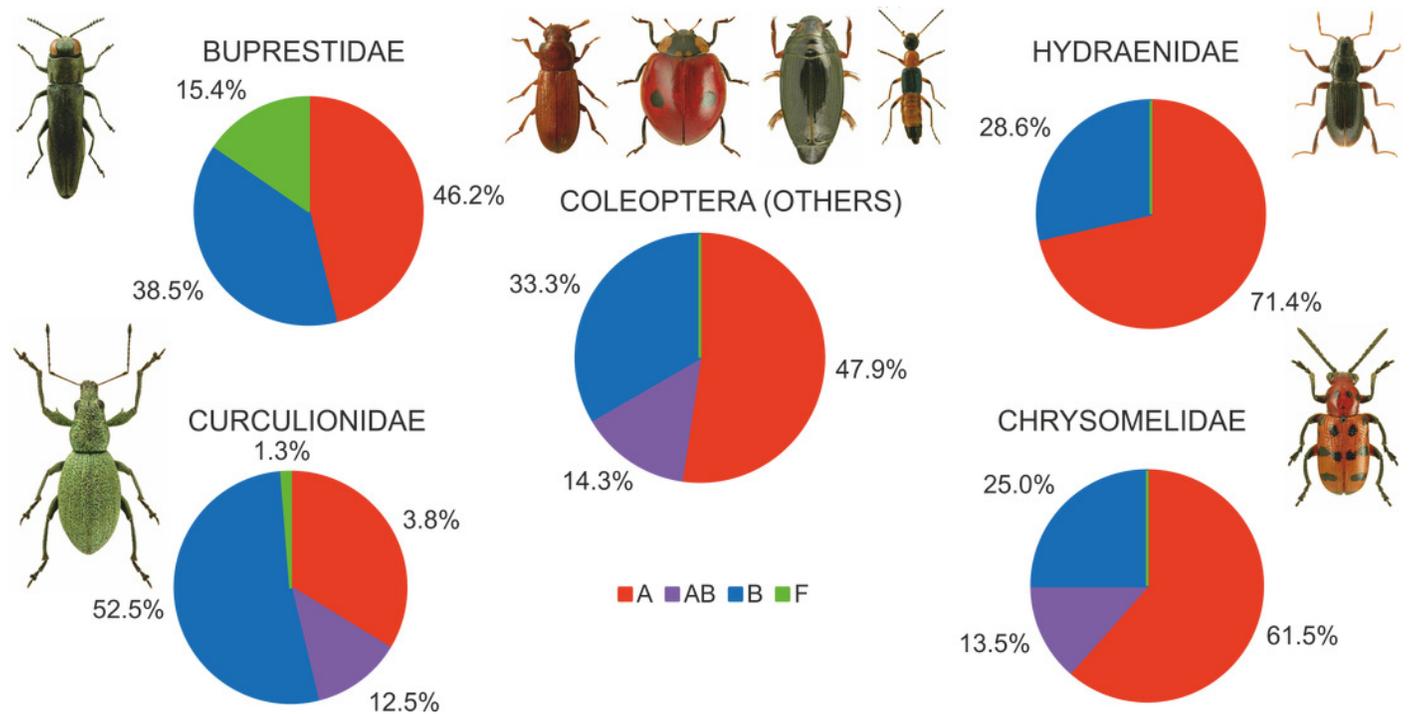

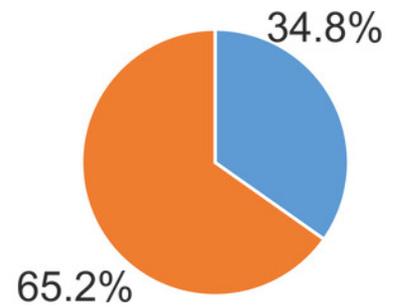

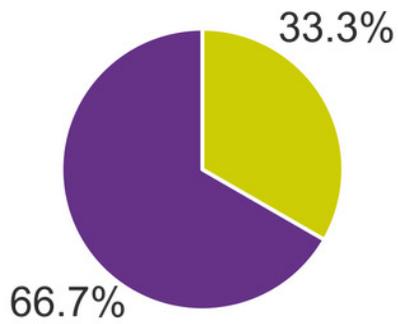

Figure 8

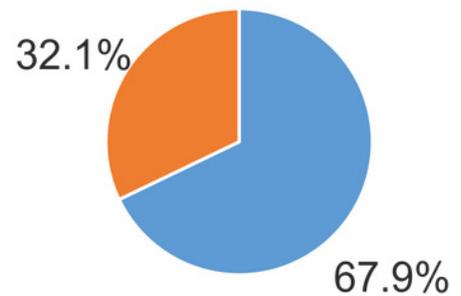

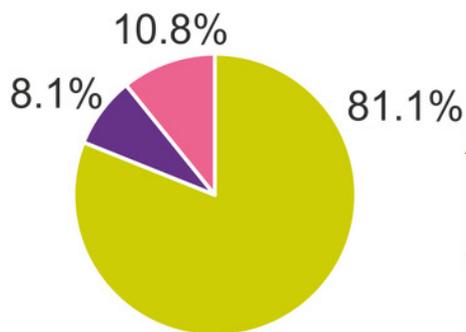

Diversity of *Wolbachia* infection in Coleoptera with respect to shares of infected individuals within species and numbers of strains found in beetles.

[Beetle photographs are from ICONOGRAPHIA COLEOPTERORUM POLONIAE (© Copyright by Prof. Lech Borowiec)].

COLEOPTERA (OTHERS)

CURCULIONIDAE

CHRYSOMELIDAE
