8 **ABSTRACT**

9 **Background.** The hatch window that varies from 24 to 48 h is known to influence post-hatch  
 10 performance of chicks. A narrow hatch window is needed for <sup>the</sup> commercial poultry industry to  
 11 acquire a high level of uniformity of chick quality. Hatching synchronization observed in avian  
 12 species presents possibilities in altering <sup>the</sup> hatch window in artificial incubation.  
 13 **Methods.** Layer eggs of different initial incubation time were mixed on day 12 of incubation.  
 14 During the hatching period, hatching time of individual eggs and hatch window were obtained by  
 15 video cameras. Embryonic development and post-hatch performance up to day 7 were measured.  
 16 **Results.** The manipulation of mixing eggs of different initial incubation time shortened the hatch  
 17 window of late incubated eggs in <sup>the</sup> manipulated group by delaying the onset of hatching process,  
 18 and improved the hatchability. Compared to control groups, chick embryos or chicks in egg  
 19 redistribution group showed no significant difference in embryonic development and post-hatch  
 20 performance up to day 7.  
 21 **Discussion.** We have demonstrated that eggs that incubated with advanced eggs performed a  
 22 narrow spread of hatch with higher hatchability, normal embryonic development as well as  
 23 unaffected chick quality. This specific manipulation is applicable in industrial poultry production  
 24 to shorten <sup>the</sup> hatch window and improve uniformity of chick quality.

## 25 INTRODUCTION

26 Hatching synchronization is of importance to precocial avian species <sup>and</sup> ~~that~~ can be achieved by  
 27 acceleration (Holmberg 1991; Vince 1964) or retardation (Persson & Andersson 1999; Vince  
 28 1968) of hatching. This adaptive advantage enables the offsprings to avoid being abandoned by  
 29 <sup>the parent bird</sup> ~~motherhood~~ and exposure <sup>d</sup> to predators (Davies & Cooke 1983). In commercial poultry  
 30 incubation, hatching synchrony essentially contributes to the uniformity of newly hatched chicks.  
 31 In general, hatch window <sup>is</sup> ~~as~~ <sup>ed as the</sup> evaluation of degree of hatching synchrony, <sup>and</sup> ~~which~~ is defined as the  
 32 time between early-hatching and late-hatching, <sup>varying</sup> ~~varies~~ from 24 to 48 hours (Careghi et al. 2005;  
 33 Decuyper et al. 2001). Thus, early hatched chicks will be held in the incubators with deprivation  
 34 of feed and water until <sup>the</sup> ~~entire~~ batch of chicks hatch <sup>es</sup>, rather than removed immediately upon  
 35 hatching. Variability of delayed time in feed access, caused by the spread of hatch, depressed  
 36 uniformity of post-hatch performance of the chicks, including organ development, immune  
 37 system activation, digestive enzyme stimulation and relative growth post hatch (Tona et al. 2003;  
 38 Willemsen et al. 2010a).

39 In artificial incubation, the inherent characteristics of eggs (e.g. parental age, egg weight and  
 40 egg storage time) and incubation conditions (temperature and CO<sub>2</sub> concentration during hatching  
 41 phase) play a crucial role in embryonic development that results in the spread of hatch (De Smit  
 42 et al. 2006; Ipek & Sozcu 2017; Maatjens et al. 2014; Nangsuay et al. 2016; Tona et al. 2003;  
 43 Tona et al. 2007; Willemsen et al. 2010b). Moreover, intraclutch hatch synchronization was found  
 44 in lesser snow goose (Davies & Cooke 1983), pheasants and mallard ducks (Persson &  
 45 Andersson 1999), by shortening or prolonging the incubation period. In addition to this effect of  
 46 sibling contact, the hatch process could also be affected by mixing eggs of different embryo

developmental trajectory (Tona et al. 2013). However, no efficient manipulations during incubation have been performed to shorten <sup>the</sup> hatch window in poultry production.

Therefore, the aim of the present study was to achieve a narrowed hatch window through the manipulation of mixing eggs of different growth curves. In addition, potential effects on embryonic development and post hatch performance were studied. Hatching time of individual chicks, hatch window, hatchability, yolk residue and organ weights, body weight and leg bone development were compared between control and manipulated groups.

## MATERIALS AND METHODS

All procedures in this study were approved by committee of the Care and Use of Animals of Zhejiang University, Hangzhou, China.

### Experimental design

Hatching eggs (n=704; weight range from 53 to 57 g) were obtained from a Hyline breeder flock at 35 to 36 wk of age (Shenhai Breeding, Shenyang, China). The eggs were divided into early incubation group (EI) and late incubation group (LI), respectively. LI started incubation 12 hours later than EI so that the biological age (BA, calculated from the initial incubation time) of EI was 12 h older than that of LI. On BA 12 d of LI (BA 12.5 d of EI), 160 eggs randomly chosen from both EI and LI were distributed into the third incubator <sup>and the</sup> ~~that~~ defined as manipulated incubation group (MI). <sup>the</sup> ~~And the~~ remaining eggs in EI and LI were regarded as control groups. The eggs in MI were distributed randomly. On BA 18 of LI, MI group were separated into EMI group (early incubated eggs in MI) and LMI group (late incubated eggs in MI) to start <sup>the</sup> ~~start~~ hatching phase.

### Incubation

Eggs were incubated and hatched in lab-scale incubators (NK-hatching, Dezhou Nongke Incubation Equipment Co. Ltd., Shandong, China) measuring 1100×1000×900 mm with a capacity of 352 eggs. The incubators were calibrated by a standard thermometer and hygrometer before egg incubation. The incubation <sup>was</sup> maintained at a temperature of  $37.8 \pm 0.1$  °C and a relative humidity around 60%. The turning time interval during incubation was two hours until day 18. Eggs were candled (Cool-Lite tester, GQF) on day 18 and those with a living embryo were transferred to hatching baskets. Fisheye cameras (DS-2CD3942F-I, HIKVISION) <sup>focussed</sup> adopted upon the hatching baskets were used to monitor the hatch process. All incubations stopped at BA 504 h of LI and chicks were removed from the incubators.

#### Post-hatch housing and management

A total of 128 newly hatched chicks (32 per incubation group) were sampled and transferred to four pens of 1 m<sup>2</sup> covered with sawdust. Artificial lightning was set for 23 h/d from day 0 to 7 (40 lux at chick <sup>'s</sup> eye ~~s~~ level). Temperature was set to 34°C, decreased by 0.5°C per day <sup>over</sup> during 7 days. Feed and water were provided *ad libitum*.

#### Data collection

On BA 18 d and 20 d of LI, six eggs or chicks that hatched at peak hatching period (30% to 70% hatch) were randomly sampled from each group <sup>were</sup> for measurements of chick embryonic development. After eggs <sup>were</sup> broken open, embryos or chicks were sacrificed by decapitation to obtain yolk weight and yolk free body weight (YFBW). Weights of heart, liver and stomach (gizzard and proventriculus) of all sampled embryos sacrificed on BA 18 d and 20 d of LI were determined.

The hatching time of individual eggs <sup>as</sup> were determined using video recordings, <sup>a</sup> And the

91 hatching time <sup>was</sup> is presented as biological age. From the first hatchling, <sup>number</sup> quantity of chicks was  
 92 <sup>recorded</sup> obtained every an hour. The chicks were removed from incubators every twelve hours to allow  
 93 the camera to <sup>maintain</sup> get a clear field of view. Hatch window was calculated by subtracting hatching time  
 94 of the last chick from that of the first chick. The peak hatching period was defined as 30% to 70%  
 95 hatch of the batch.

96 At BA 504h of LI (516 h of EI), 32 chicks per group which hatched in <sup>the</sup> peak hatching period  
 97 were sampled and weighed. Metatarsus length (ML) was measured for assessment of leg bone  
 98 development. After seven days' growing <sup>th</sup>, all chickens received <sup>the</sup> same measurements to evaluate  
 99 post-hatch development.

## 100 Statistical analysis

101 A one-way ANOVA model (SPSS 19.0) was used to analyze the effects of egg redistribution  
 102 on the embryonic development of chicks (<sup>y</sup>Yolk free body weight, yolk weight, heart weight, liver  
 103 weight and stomach weight) and post hatch performance (chick weight and tibia length). The  
 104 level of significance was set at  $P < 0.05$ . The Fisher's LSD method was performed to test for  
 105 overall differences among treatment groups. All data are shown as average  $\pm$  S. E. M.

## 106 RESULTS

### 107 Hatch performance

108 The distribution of hatching time was obtained by video recordings of <sup>the</sup> four treatment groups.  
 109 The EI group was found to give the first hatchling as expected, and the hatch window was 38  
 110 hours (Figure 1. a). However, hatch <sup>ing</sup> process <sup>the</sup> of EMI group started 5 hours later than EI, while it  
 111 finished at the same time as <sup>the</sup> EI group (Figure 1. b). The start-up time of egg incubation in LI and  
 112 LMI groups were 12 hours later than those of EI and EMI. As a result, first chicks of LI and LMI

113 groups emerged from eggs 2 and 8 hours later than EI group, respectively. The hatch process of <sup>the</sup>  
 114 LI group lasted 30 hours (Figure 1. c), 8 hours shorter compared to <sup>the</sup> EI group. Moreover, <sup>the</sup> LMI  
 115 group had a shortened hatch window of 21 hours with highest hatchability (95.8%), even though  
 116 it started at 468 h (Figure 1. d) which was 6 hours later than LI. According to 30% and 70% hatch  
 117 time in Figure 2, the peak hatching period of manipulated incubation groups (EMI: 472.3 -478.8  
 118 h; LMI: 475.0 – 480.4 h) was delayed 1.9 to 2.7 hours compared to the control groups (EI: 470.4  
 119 -477.0; LI: 472.1 – 478.7). Furthermore, the duration of peak hatching period in EMI was  
 120 shortest (5.4 hours) which was consistent with the narrow hatch window.

#### 121 Embryonic development from day 18 until hatch

122 Embryonic development of <sup>the</sup> four groups on BA 18 d of LI <sup>is</sup> was shown in Table 1. Yolk free  
 123 body weight was higher ~~than~~ in early incubation groups (EI and EMI) than late incubation groups  
 124 (LI and LMI), but yolk weight of early incubated eggs (EI and EMI) was found significantly  
 125 lower than late incubated eggs (LI and LMI). In addition, organ size (heart weight and liver  
 126 weight) was larger in EI and EMI, mainly caused by higher YFBW. <sup>However</sup> ~~Whereas~~, no significance <sup>+ difference</sup> of <sup>for</sup>  
 127 stomach weight was found.

128 The four incubation groups hatched in <sup>the</sup> peak hatching period had similar YFBW (Table 2).  
 129 Due to the earlier peak hatching period of chicks ~~in four groups~~, yolk absorption of EI was faster  
 130 and those chicks had higher liver and stomach weight. And LMI chicks that had short holding  
 131 time in incubator hatched with significantly higher yolk weight, lower liver and stomach weight.  
 132 However, heart development of all hatched chicks was similar ~~in all groups~~.

133 Overall, there were no significant differences between EI and EMI or LI and LMI in YFBW,  
 134 yolk absorption and organ size. No effects of egg redistribution were observed for embryonic

135 development both on BA 18 d and 20 d of LI.

# 136 Post-hatch performance until day 7

137 The evaluation of post-hatch performance until day 7 <sup>is</sup> was presented in Table 3. At peak hatching  
138 time of LMI (480 h), body weight of chicks in early incubation groups (EI and EMI) was lower  
139 due to weight loss <sup>during the</sup> in holding period <sup>the</sup> in hatchers, while EI and EMI chicks had higher ML.  
140 <sup>However</sup> Whereas, no significant difference was found between EI and EMI, as well as <sup>between</sup> LI and LMI.  
141 Similar results occurred after seven days' growth. Although both body weight and ML of early  
142 incubation groups (EI and EMI) were slightly higher than those of <sup>the</sup> late incubation groups (LI and  
143 LMI), post hatch growth and leg bone development was not altered by the manipulation of egg  
144 redistribution.

# 145 DISCUSSION

146 The aim of this study was to investigate the effects of egg redistribution during incubation  
147 on hatching time and post-hatch development. The results demonstrate that mixing eggs of  
148 different developmental stages during incubation influenced <sup>the</sup> hatching process, including delayed  
149 hatching time and shortened hatch window. They also suggest that embryonic development and  
150 post-hatch performance were not altered by egg redistribution on BA 12 d of LI.

151 Hatching time is known to be influenced by factors such as parental age, egg storage time  
152 and conditions, and incubation conditions (Careghi et al. 2005; Decuyper & Bruggeman 2007;  
153 Tona et al. 2003). <sup>H</sup> And <sup>also</sup> hatching time distribution results in different chick qualities and  
154 physiological characteristics in one batch of hatched chicks (Careghi et al. 2005; Wang et al.  
155 2014). To eliminate these factors, eggs were obtained from a single breeder flock, laid on the  
156 same day, stored with very short time (no more than 2 days), and incubated in incubators with

157 temperature and relative humidity calibration. Thus, the manipulation of egg redistribution on  
 158 day 12 <sup>was presumed to</sup> ~~might~~ be the only factor that affect the hatching time in this study.

159 The present study confirmed that mixing eggs of different growth curves shortened the hatch  
 160 window of <sup>the</sup> redistribution <sup>ed</sup> group, which is consistent with hatching synchronization found in  
 161 pheasants (Persson & Andersson 1999). The onset of <sup>the</sup> hatching process in redistributed eggs was  
 162 retarded 5 to 6 hours, indicating that the narrow hatch window was related to delay of the first  
 163 hatch in <sup>the</sup> manipulated group. This might be explained by some kinds of egg communication  
 164 between early incubated eggs and late incubated eggs. Chick embryos begin to develop a  
 165 functionary auditory system as early as day 10 of incubation (Alladi et al. 2002). Specific  
 166 interaction among redistributed eggs may take place after mixing eggs, by means of embryo  
 167 sound communication. Perception of vocalizations by embryos may lead to physiological or  
 168 behavioral changes. This <sup>is consistent with</sup> ~~confirms~~ the finding of Tong (2015) that delayed internal piping time  
 169 when embryos were exposed to embryo sound stimulation. However, ~~an~~ increased mortality was  
 170 observed in duck and chicken eggs that were incubated under artificial sound stimulation (Tong  
 171 et al. 2015a; Veterany et al. 1999). Compared to the artificial sound stimulation, embryo  
 172 vocalization may <sup>impose</sup> ~~lay~~ less stress on other hatching eggs <sup>and</sup> ~~that exerts~~ no negative impact on  
 173 hatchability. Another hypothesis is that environmental CO<sub>2</sub> <sup>s</sup> ~~altered~~ the hatch process and results  
 174 in <sup>a</sup> narrow spread of hatch. Previous <sup>r</sup> ~~researches~~ reported that high levels of CO<sub>2</sub> during early  
 175 stages of incubation stimulated early hatching and shortened <sup>the</sup> hatch window (De Smit et al. 2006;  
 176 Tona et al. 2007). Although the onset of hatching process of mixed eggs was delayed compared to  
 177 the control groups, this did not extend the spread of <sup>the</sup> hatch. The early incubated embryos may  
 178 penetrate the membrane and eggshell, <sup>and</sup> generate more CO<sub>2</sub> <sup>the</sup> during hatching period, leading to

179 increasing CO<sub>2</sub> concentration that stimulated the hatching process of late incubated eggs.

180 Furthermore, the increasing<sup>CO<sub>2</sub></sup> concentration potentially contributes to hatchability of LMI (95.8%)

181 - higher than the other groups - suggests<sup>ing</sup> that more chick embryos succeeded in breaking out of<sup>the</sup> the

182 eggshell rather than died in this<sup>difficult</sup> tough process. Considering this delayed onset of hatching<sup>the</sup>

183 process, the narrow spread of hatch and the increased hatchability, our future work will focus on

184 identifying<sup>as</sup> to what degree and via which mechanisms, redistributing eggs of different growth

185 curves affects hatching pattern and hatchability.

186 The advanced embryonic development of early incubated eggs was observed in both control

187 (EI) and manipulated group (EMI), mainly caused by the initial incubation time difference of 12

188 hours. However, mixing eggs of different growth curves did not alter the embryonic growth and

189 yolk absorption before hatch. Chick embryos of both early incubated and late incubated eggs

190 were able to maintain normal organ development and nutrient metabolism until hatch. Although

191 earlier hatched chicks (EI and EMI) underwent a longer holding period in incubators, the

192 decreased yolk weight and increased organ weight indicated an advanced maturation of organs

193 post hatch, as supposed by previous studies (Pinchasov & Noy 1993; Tong et al. 2015b; Van de

194 Ven et al. 2011).<sup>At</sup> Long time<sup>with</sup> no access to feed and water (EI and EMI, 36 h; LI and LMI, 24 h)

195 resulted in a higher weight loss<sup>the</sup> in early incubation groups (EI and EMI), but enhanced the leg

196 bone development. The consistency of body weight and leg bone development on day 7 was

197 observed as expect<sup>ed</sup>. Nevertheless, the narrow hatch window of manipulated groups did not

198 influence chick growth performance up to day 7, indicating that egg distribution only stimulates

199 the hatching behavior. However, there is no evidence that response to eggs or egg communication

200 by egg distribution was related to this shortened hatch window. As<sup>reported</sup> above, there was no negative

201 effect of mixing eggs of different growth curves on embryonic growth, utilization of nutrients and  
202 post-hatch performance.

# 203 CONCLUSION

204 The specific manipulation of mixing eggs of different initial incubation time influenced  
205 hatching pattern, including onset of hatching process and hatch window. The egg redistribution  
206 during incubation did not affect normal embryonic development, utilization of nutrients and post-  
207 hatch performance. All of these results <sup>are</sup> ~~will be~~ <sup>the</sup> applicable in industrial hatchery to shorten <sup>the</sup> hatch  
208 window and improve uniformity of chicks.

# 209 ACKNOWLEDGEMENTS

210 We would like to thank Kailao Wang for assistance of video camera. We also thank  
211 Zhanming Li (College of Quality & Safety Engineering, China Jiliang University) for his  
212 suggestions.
