# 20 Abstract

21 Among copepods, which are the most abundant animals on Earth, the genus *Oithona* is described  
 22 as one of the most numerous and plays a major role in the marine food chain and biogeochemical  
 23 cycles, particularly through the excretion of chitin-coated faecal pellets. Despite the morphology  
 24 of several *Oithona* species is well known, knowledge of its internal anatomy and chitin  
 25 distribution is still limited. To answer this problem, *Oithona nana* and *Oithona similis*  
 26 individuals were stained by WGA-FITC and DAPI for fluorescence microscopy observations.  
 27 The image analyses allowed a new description of the organization and chitin content of the  
 28 digestive and reproductive systems of *Oithona* male and female. Chitin microfibrils were found  
 29 all along the digestive system from the stomach to the hindgut with a higher concentration at the  
 30 peritrophic membrane of the anterior midgut. Several midgut shrinkages were observed and  
 31 proposed to be involved in faecal pellet shaping and motion. Amorphous chitin structures were  
 32 also found to be a major component of the ducts and seminal vesicles and receptacles. The rapid  
 33 staining protocol we proposed allowed a new insight into the *Oithona* internal anatomy and  
 34 highlighted the role of chitin in the digestion and reproduction. This method could be applied to  
 35 a wide range of copepods in order to perform comparative anatomy analyses.

# Introduction

Copepods are the most abundant animals on Earth ahead of insects and nematodes (Humes 1994) and inhabit all aquatic niches: groundwater, vernal ponds, glaciers, lakes, rivers and oceans (Huys & Boxshall 1991). Among marine copepods, *Oithona* has been described as the most important marine planktonic genus in terms of abundance (Gallienne & Robins 2001). A recent study, based on the *Tara* Oceans metagenomic data, has shown the global distribution of *Oithona* in coastal and open ocean waters (Madoui *et al.* 2017), which highlighted its key role as a major secondary producer of the marine food chain (Beaugrand *et al.* 2003; Zamora-Terol *et al.* 2014). The important contribution of copepods in the biological carbon pump has also been demonstrated (Jonasdottir *et al.* 2015), in particular through the excretion of faecal pellets (Steinberg & Landry 2017) that sink, provide organic and inorganic compounds to microplankton (Steinberg *et al.* 2002; Valdés *et al.* 2017), and deposit on the sediments where they could remain as fossils for several thousand years (Bathmann *et al.* 1987; Haberyan 1985). The biochemical analysis of the copepod faecal pellets has revealed a high amount of chitin (Kirchner 1995), a beta-1-4 N-acetylglucosamine polymer, the most abundant biopolymer in nature after celluloses (Kirchner 1995), and mostly known in copepods as a component of the exoskeleton. Besides the role of copepods in the carbon pump, the abundance of chitin in the faecal pellets also points out the implication of copepods in the global nitrogen cycle (Frangoulis *et al.* 2004).

Morphological traits of more than forty *Oithona* species are well known (Razouls *et al.* 2005-2018), especially the structure of the antennules, the oral appendages, the swimming legs and the caudal rami (Nishida 1985). However, such morphological traits are only accessible through finical dissections under the microscope that need expertise and are time-consuming. Recently,

59 molecular tools have proven their usefulness in species identification (Cornils *et al.* 2017;  
60 Madoui *et al.* 2017).

61 The detailed external anatomy of copepods has been analyzed through Congo red fluorescence  
62 (Michels & Büntzow 2010) and through electron microscopy that allowed the species  
63 identification of copepods and the characterization of their external structures (Chang 2013;  
64 Cuoc *et al.* 1997; Marques *et al.* 2017). Using an electron microscope, *Oithona nana* Giesbrecht,  
65 1892 female sexual orifices with attached male spermatophores were observable (Huys &  
66 Boxshall 1991). Diagrams of marine and freshwater cyclopoids, which provide the structures of  
67 the reproductive and digestive systems (Borradaile & Potts 1935; Dussart & Defaye 2001;  
68 Kellogg 1902) were available. Some studies proposed methods to observe the reproductive  
69 system of aldehyde-preserved copepods by direct light microscopy observation of individuals  
70 (Eisfeld & Niehoff 2007; Niehoff 2003; Niehoff & Hirche 1996; Tande & Hopkins 1981), by  
71 staining of gonad with borax carmine (Tande & Gronvik 1983; Tande & Hopkins 1981), with  
72 fluorescent polyunsaturated aldehydes (PUAs) probes (Wolfram *et al.* 2014), or with Fast Green  
73 (Batchelder 1986). The internal anatomy of *Oithona similis* Claus, 1863 has been recently  
74 described using phase contrast microscopy and provided the first insight into the organization of  
75 the *Oithona* female reproductive system (Mironova & Pasternak 2017). In the Wolfram *et al.*  
76 study, some pictures of the calanoid *Acartia tonsa* obtained using fluorescent PUA probes, also  
77 allowed to determine the anatomy of the digestive system. Other studies (Bautista & Harris  
78 1992; Debes *et al.* 2008) used the chlorophyll fluorescence to determine the ingestion rates and  
79 the gut contents, but without providing a clear structure of the digestive organs. Electron  
80 microscopy revealed that chitin microfibrils are present in the anterior and posterior midgut

peritrophic membrane (PM) of free-living and in the posterior PM of parasitic copepods (Yoshikoshi & Kô 1988), but no *Oithona* species have been included in the study.

For a better understanding of the ecological success of *Oithona*, a detailed knowledge of its internal anatomy is crucial. Fluorescence microscopy based on a double staining coupling Wheat Gamma Agglutinin-Fluorescein IsoThioCyanate (WGA-FITC) and DiAmidino-2-PhenylIndole (DAPI) were used to elucidate the internal anatomy. DAPI is a blue fluorescent protein which has an affinity to two nucleoids: adenine and thyrosin (Lin *et al.* 1977). This staining is widely used to detect DNA in eukaryotes, prokaryotes and some viruses, without tissue-specificity. FITC is a green fluorescent protein that can be conjugated with a wheat lectin that has an affinity and specificity to N-acetyl- $\beta$ -D-glucosamine (Allen *et al.* 1973). WGA-FITC staining is widely used for chitin detection by fluorescence, in a liquid medium containing lysed cells or directly on whole organisms (El Gueddari *et al.* 2002; Farnesi *et al.* 2015; Fones *et al.* 2016; Godoy *et al.* 2015). On copepods, WGA-FITC was used only once; but after dissolution of the soft tissues which did not allow the investigation of the internal anatomy (Mravec *et al.* 2014). In the present study, we used WGA-FITC and DAPI staining to provide a new insight into the internal anatomy and chitin content of *Oithona nana* and *Oithona similis* with a focus on their digestive and reproductive systems.

# Material and methods

## Biological materials samples

*Oithona nana* and *O. similis* specimens were sampled at two locations of the Toulon harbor, France, at the East of the little harbor of Toulon (Lat 43° 06' 52.1" N and Long 05° 55' 42.7" E) and the North of the great harbor of Toulon (Lat 43° 06' 02.3" N and Long 05° 56' 53.4" E).

Sampling took place in November 2016, January, March and June 2017. The samples were collected from the upper water layers (0-10m) using zooplankton nets with a mesh of 90µm and 200µm. Samples were preserved in 70% ethanol and stored at -4°C. In the samples, individuals of the four different development stages were observable (nauplii, copepodites and adults of both sexes), but the large majority were female adults.

### Individual staining

This protocol was adapted from Farnesi *et al.* After gently mixing the ethanol preserved samples (about 20 reversals), 100µL were sampled in a 1.5mL tube. After two minutes, the ethanol was removed, and 100µL of Phosphate Buffered Saline (PBS) at 1X and 10µL of WGA-FITC at 2mg mL<sup>-1</sup> (Sigmaaldrich.com 2017b) were added for chitin staining. After mixing, the sample was incubated for 30 minutes protected from light before supernatant removing. To stain the DNA, dual staining with DAPI can be performed by adding, 100µL of PBS at 1X and 10µL of DAPI (Sigmaaldrich.com 2017a) at 10X. The microscopy observations were done directly after mixing. This protocol can also be used on living individuals from a seawater sample; in this case, sodium chloride at 39g L<sup>-1</sup> has to be added to the PBS solution.

### Microscopy

The stained individuals were placed between slide and coverslip and observed under a reflected fluorescence microscope Olympus BX43. WGA-FITC was excited with the 460/495nm line from a 100W mercury lamp with an interference excitation filter (BP460), and collected with a 505nm dichroic mirror (DM505) and a 510nm interference barrier filter (BA510IF). DAPI fluorescence was excited with the 340/390nm line from a 100W mercury lamp with an interference excitation filter (BP340), and collected with a 410nm dichroic mirror (DM410) and

125 a 420nm interference barrier filter (BA420IF). Selected *Oithona* individuals were photographed  
 126 with a sixteen-megapixel camera using the ToupView software (v.3.7). For each individual, three  
 127 photographs were taken: one in polarized light, one with the WGA-FITC fluorescence and one  
 128 with the DAPI fluorescence. Some colour adjustments were made with the ImageJ software  
 129 (Schneider *et al.* 2012).

## 130 **Results**

### 131 ***Oithona* morphology with WGA-FITC microscopy**

132 The *Oithona* chitin was labelled with WGA-FITC directly on the individuals and observed by  
 133 fluorescence microscopy. The setae and spines of the exopod segments of the five leg pairs could  
 134 be identified and counted on *O. nana* (Figure 1.A). These first results revealed the chitinous  
 135 structure of the setae and the spines, and could provide a rapid method for taxonomical  
 136 identification. However, because of the individuals and setae position on the plate, we were not  
 137 able to identify and count the setae of all tested individuals. Chitinous elliptic or spherical  
 138 structures of unknown function and larger than 6 micrometres (Figure 1.A) were also visible in  
 139 the exopods of the swimming legs. These globular structures were observed in both sexes of  
 140 *O. nana* (Figure 1.A, 2.A, 2.B, 2.C, 2.D, 2.E), but only in female individuals of *O. similis* (Figure  
 141 2.F, 2.G). They may also be smaller (2.F), or absent (Figure 3.A, 4.C) in other individuals. These  
 142 structures can also be present in other exopod segments (Figure 2.A). Another tubular structure,  
 143 in the distal part of the exopods 3 of the right third leg, right and left fourth legs and right and left  
 144 fifth legs were noticeable (Figure 1.A). In other *Oithona* individuals, these tubular structures  
 145 appear to be attached to the globular structure (Figure 2.B, 2.D, 2.G).

### 146 **Chitin distribution in the *Oithona* digestive system**

Chitin was detected all along the digestive system, from the stomach to the hindgut of the nauplius (Figure 1.B) and adults (Figure 1.C, 1.D, 1.E) of the two species. The exoskeleton chitin was also stained by the WGA-FITC, which allowed a clear identification of the stomach in the prosome, of the midgut in the prosome and in the urosome and the hindgut in the urosome. Along the digestive system, the chitin had a microfibrillar structure aligned along the antero-posterior axis with regions showing higher microfibrils density, especially the anterior midgut and some stomach areas (Figure 1.C, 1.D, 1.E, 1.F). Some individuals contained in their anterior and posterior midgut one or several elliptical faecal pellets completely engulfed by chitin (Figure 1.E, 4.B). However, no faecal pellets were found in the nauplius. In the anterior and posterior midgut, we observed several shrinkages at different interval distances corresponding to midgut contractions. In certain cases, several shrinkages (up to four) were separated by less than five micrometres (Figure 1.D), while other individuals showed more distant shrinkages (Figure 1.F).

### **Chitin distribution in the *Oithona* reproductive system**

The DAPI and WGA-FITC stainings on *Oithona* females allowed the identification of the ovaries and the oviducts that presented a heart shape in the middle of the prosome (Figure 3.A, 3.B) as previously described by Mironova & Pasternak. The oviducts start from each lateral side of the gonads to the seminal receptacle in the genital double somite (the first two segments of the urosome). Comparing to the microfibrillar structure of the chitin found in the digestive system, the chitin staining in the reproductive system was mainly amorphous. Besides, its distribution was discontinuous along the ducts, altering chitin-rich and poor areas (Figure 3.C, 3.D).

In females, we distinguished two parts forming the seminal receptacle (Figure 3.E, 3.F). The first part was chitin-rich and located in the anterior region of the receptacle. The chitin distribution

between the anterior receptacle and the oviduct was discontinuous. The second part was located in the posterior receptacle and contained less and sparser chitin, presenting a mix of microfibrillar and amorphous structures. Thanks to DAPI staining, in some females, the presence of the DNA rich material in the posterior region of the seminal receptacle was observed and was likely to be male semen.

In males, the chitin staining allowed the identification of the spermiducts, which presented the same chitin pattern observed in the oviducts (Figure 4.A, 4.C). The spermiducts probably start from each side of the male gonads (not visible on the pictures) to the seminal vesicles, in the sexual somite (Figure 4.B). As for the female seminal receptacle, the male seminal vesicle can be divided into two parts (Figure 4.D, 4.E). The first part of the vesicles is chitin-rich, located in the anterior region of the vesicle. The distribution of the chitin from this upper part of the vesicle to the spermiduct was not continuous. The second part, located in the posterior region of the vesicle, was observed by DAPI staining and was likely to be filled by DNA-rich male semen.

## Discussion

Comparing to previous staining methods used to observe the digestive and reproductive systems of copepods (Batchelder 1986; Eisfeld & Niehoff 2007; Mironova & Pasternak 2017; Niehoff 2003; Niehoff & Hirche 1996; Tande & Gronvik 1983; Tande & Hopkins 1981; Wolfram *et al.* 2014), the protocol proposed here allows a clear insight into the chitin distribution in these systems. Moreover, this protocol is simple and rapid, taking a few minutes of manipulation, thirty minutes of incubation, and can be used on living, but also on alcohol-preserved copepods. The main limit of our method remains in the short-time staining of the WGA-FITC: a picture must be taken, a few minutes after fluorescence excitation to save any microscopic observation

without loss of quality. Furthermore, for the reproductive system, the DAPI staining allows only the observation of the gonad structure; while the Mironova and Pasternak protocol allows a better identification of the oocytes.

The use of WGA-FITC revealed chitinous spherical structures in the exopods of the swimming legs in *O. nana* males and females and in *O. similis* females, which were not observed in previous studies. The absence of these structures in *O. similis* male individuals may be a bias due to their low presence in our samples. Despite, luminescence is not conspicuous in *Oithona*, these structures could be luminous glands (Herring 1988). The green staining revealed also a chitinous tubular structure in the exopods penultimate segment of the swimming legs. These structures resemble the ‘Crusalis organ’, an osmoregulatory structure that was described by Johnson *et al* in 2014 from the coastal/estuarine copepod *Eurytemora affinis*. Since the globular and the tubular structures seemed attached, we suggest they form only one organ involved either in bioluminescence, osmoregulation or both.

The WGA-FITC staining allowed also the identification of the chitin distribution in the *Oithona* organs, which provides a high-quality view of the external and internal anatomy and pointed out the major role of chitin in the *Oithona* digestion and reproduction. According to insect studies, the distribution of chitin in the digestive system is limited to the midgut (Hegedus *et al.* 2009; Terra 2001). The same chitin distribution was observed in decapods (Martin *et al.* 2006; Wang *et al.* 2012). In both *Oithona* species, we detected chitin throughout the digestive system, which distinguishes it from insects and decapods, but seems consistent with observations in other free-living cyclopoids made by Yoshikoshi and Kô, in 1988.

In the PM of some insects (Hegedus *et al.* 2009; Kelkenberg *et al.* 2015; Lehane 1997), chitin plays a role in protection (chemical, mechanical and against viruses, bacteria and pathogens) and digestion (Terra 2001). As the synthesis of chitin has a significant metabolic cost for the organism, we hypothesized that, like the insects and decapods PM, the formation of a chitin coat around faecal pellets help to protect against toxins and pathogens that were not degraded during digestion.

In copepods, no evidence of midgut contraction has previously been described although the phenomenon has been suggested at several instances (Gauld 1957). We suppose that the midgut shrinkages observed in this study could play a key role in the formation and motion of the faecal pellets to the anus. However, we observed intestine shrinkages without the presence of faecal pellets, and vice versa. As proposed by Yoshikoshi and Kô for other copepods, we also suggest that, in *Oithona*, the formation of chitin coat around the faecal pellets can be produced by engulfing digested food in chitin microfibrils present in the PM of the anterior midgut (Figure 5).

The presence of chitin along the oviduct and spermiduct walls validates the cuticular appearance of the ducts described by Cuoc *et al.* In all *Oithona* males, we observed a pair of spermiducts, while in *Calanus finmarchicus* one of the two spermiducts disappeared during the male differentiation (Tande & Hopkins 1981). The bipartite structure of the seminal receptacles and vesicles found in *O. nana* and *O. similis* males and females were very similar. In males, we hypothesized that the chitinous structure of the vesicle plays a role in the holding of the spermatophores during their formation. Likewise, in the females, this structure would play a role in the holding of the ovisac but also in the opening and closing of the oviduct to release oocytes in the seminal receptacle.

# Conclusion

With this study, we adapted and tested a simple and rapid chitin-staining protocol that can help to the taxonomic identification of copepods, and enable new studies on copepod comparative anatomy at a larger scale. The application of the method to *Oithona* extended the knowledge of the structure of its digestive and reproductive systems. Considering the important role of copepods in the carbon and nitrogen sequestration through chitin synthesis, more efforts should be undergone to better understand the molecular and physiological mechanisms involved in faecal pellets formation.

# Figure 1(on next page)

*Oithona* appendages morphology and digestive system by WGA-FITC fluorescence microscopy.

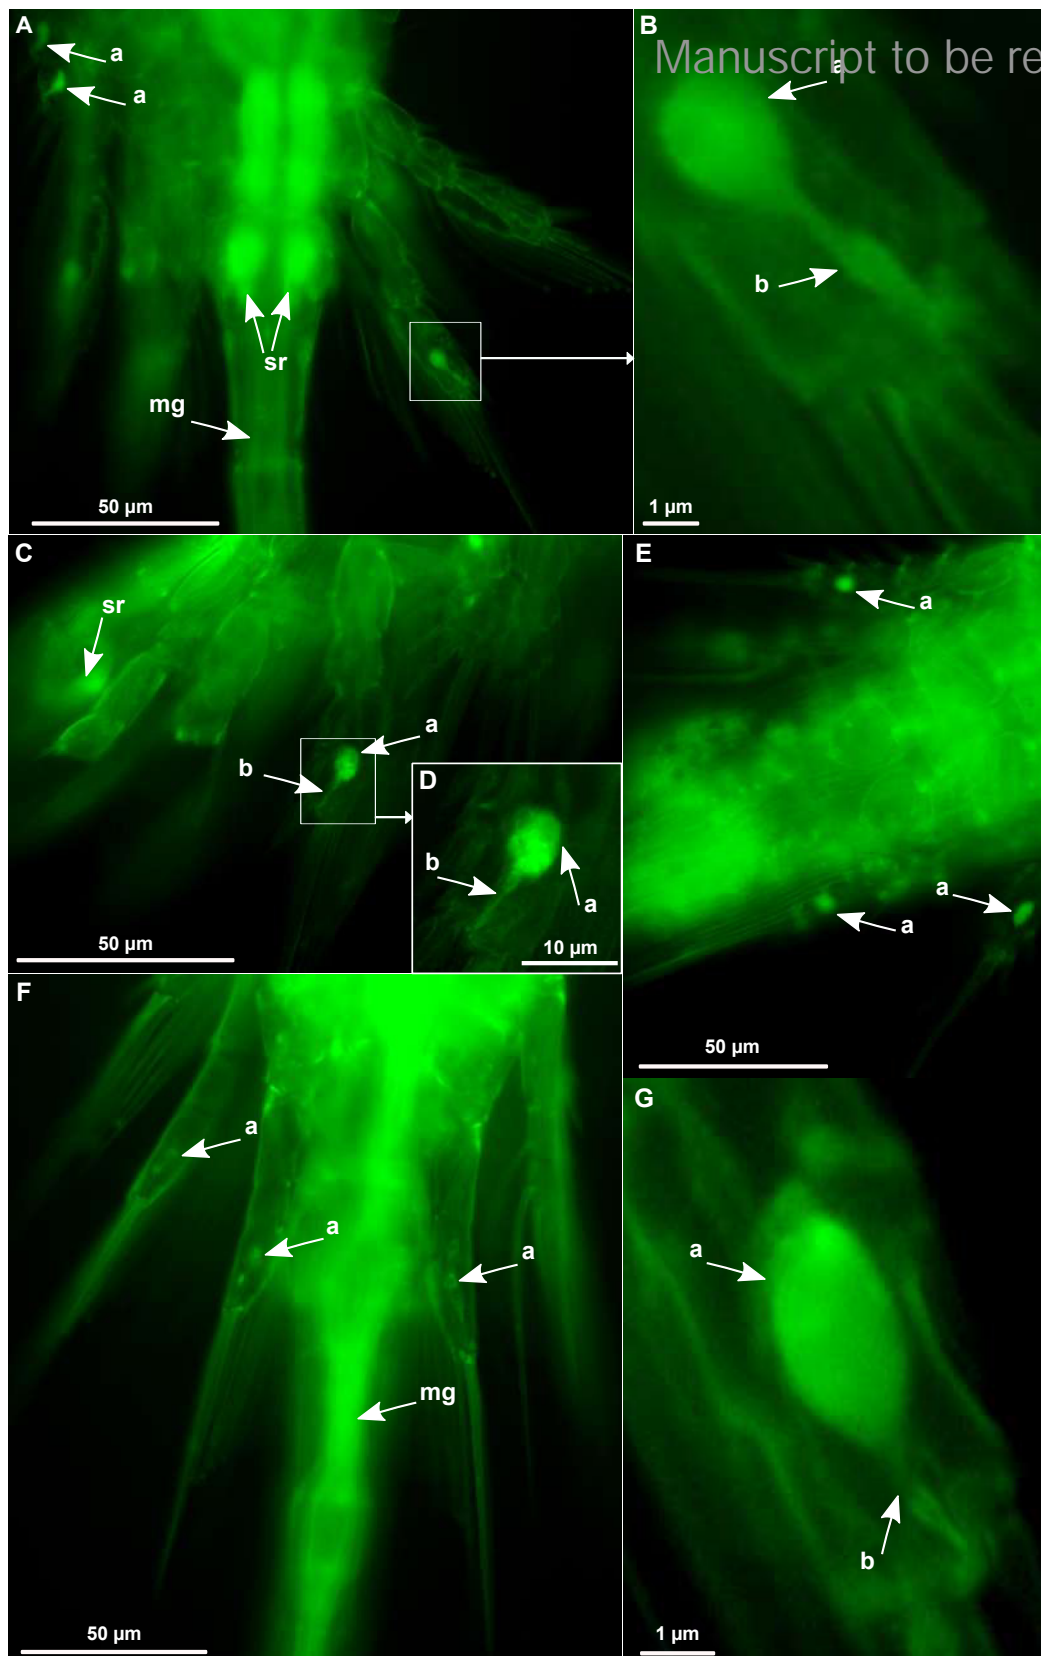

**st**: stomach, **mg**: midgut, **hg**: hindgut, **sh**: shrinkage, **ex**: exopod, **se**: setal, **sp**: spine, **fp**: fecal pellet, **a**: globular structure, **b**: tubular structure. **A**. Dorsal view of the *O. nana* female swimming appendages. **B**. Lateral view of the *Oithona* nauplius digestive system. **C**. Lateral view of the *O. nana* female stomach. **D**. Dorsal view of the *O. nana* female stomach. **E**. Lateral view of an *O. nana* male gut. **F**. Dorsal view of an *O. similis* female adult stomach.

## Figure 2(on next page)

*Oithona* globular and tubular chitinous structures in the swimming appendages by WGA-FITC fluorescence microscopy.

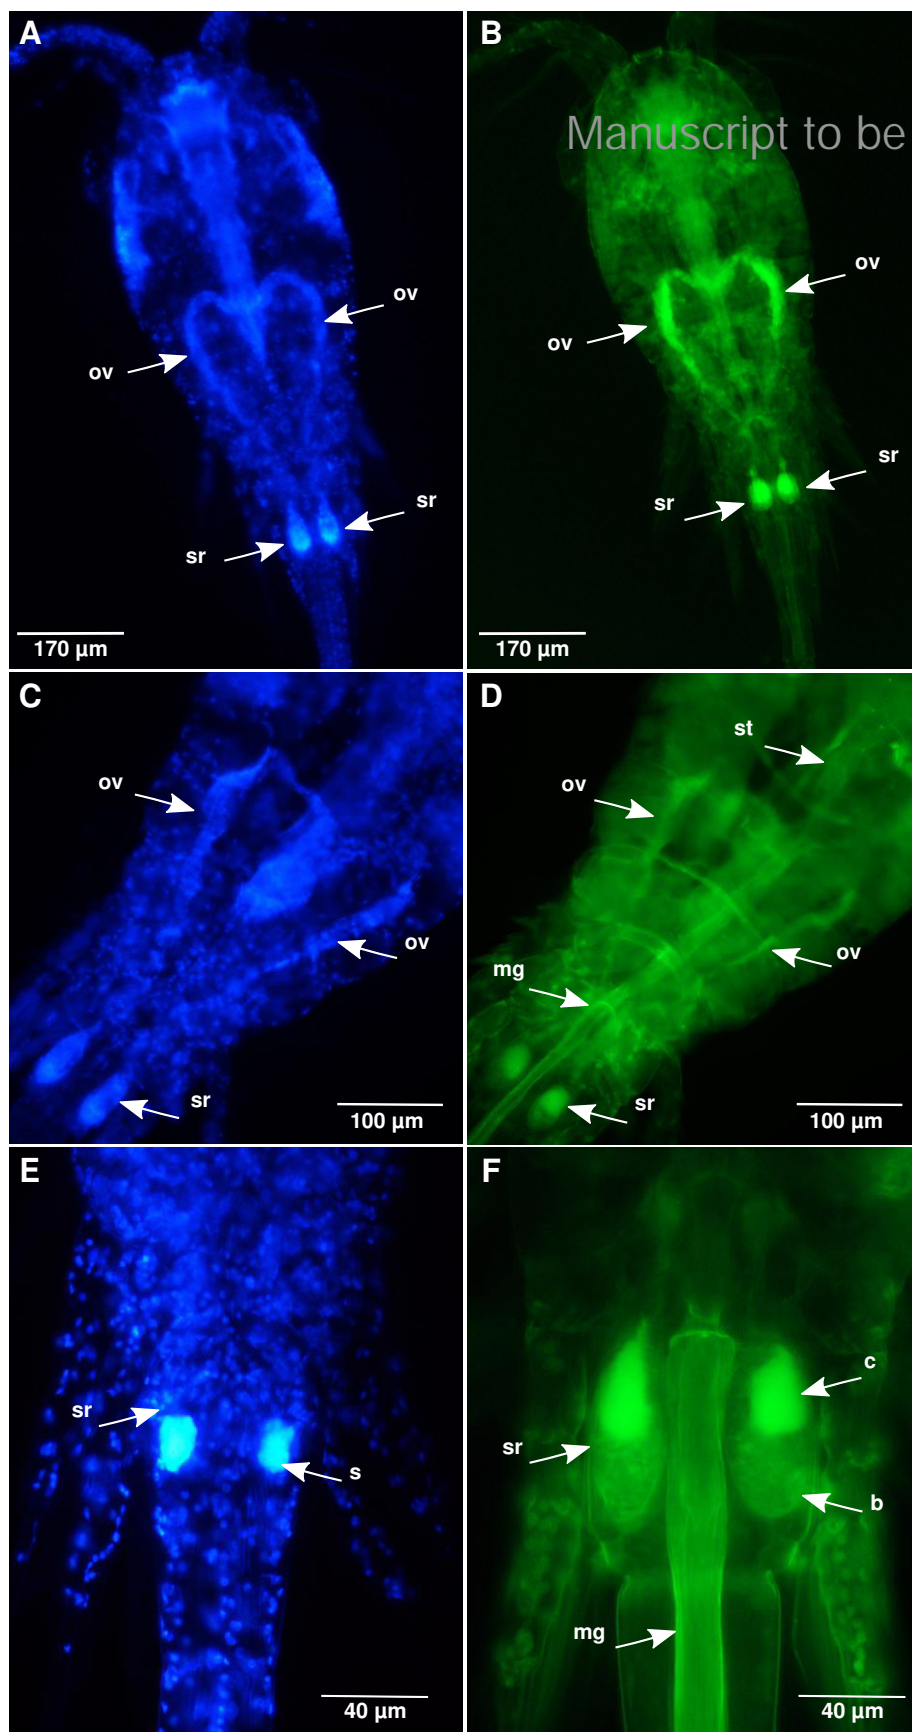

**mg**: midgut, **sr**: seminal receptacle, **s**: semen, **ov**: oviduct, **hg**: hindgut, **b**: diffuse chitin region, **c**: chitin rich region. **A**. Dorsal view of the *O. nana* female reproductive system. **B**. Dorsal view of the *O. similis* female reproductive system. **C**. Dorsal view of the *O. nana* female double sexual somite.

# Figure 3(on next page)

*Oithona* female reproductive system by DAPI and WGA-FITC fluorescence microscopy

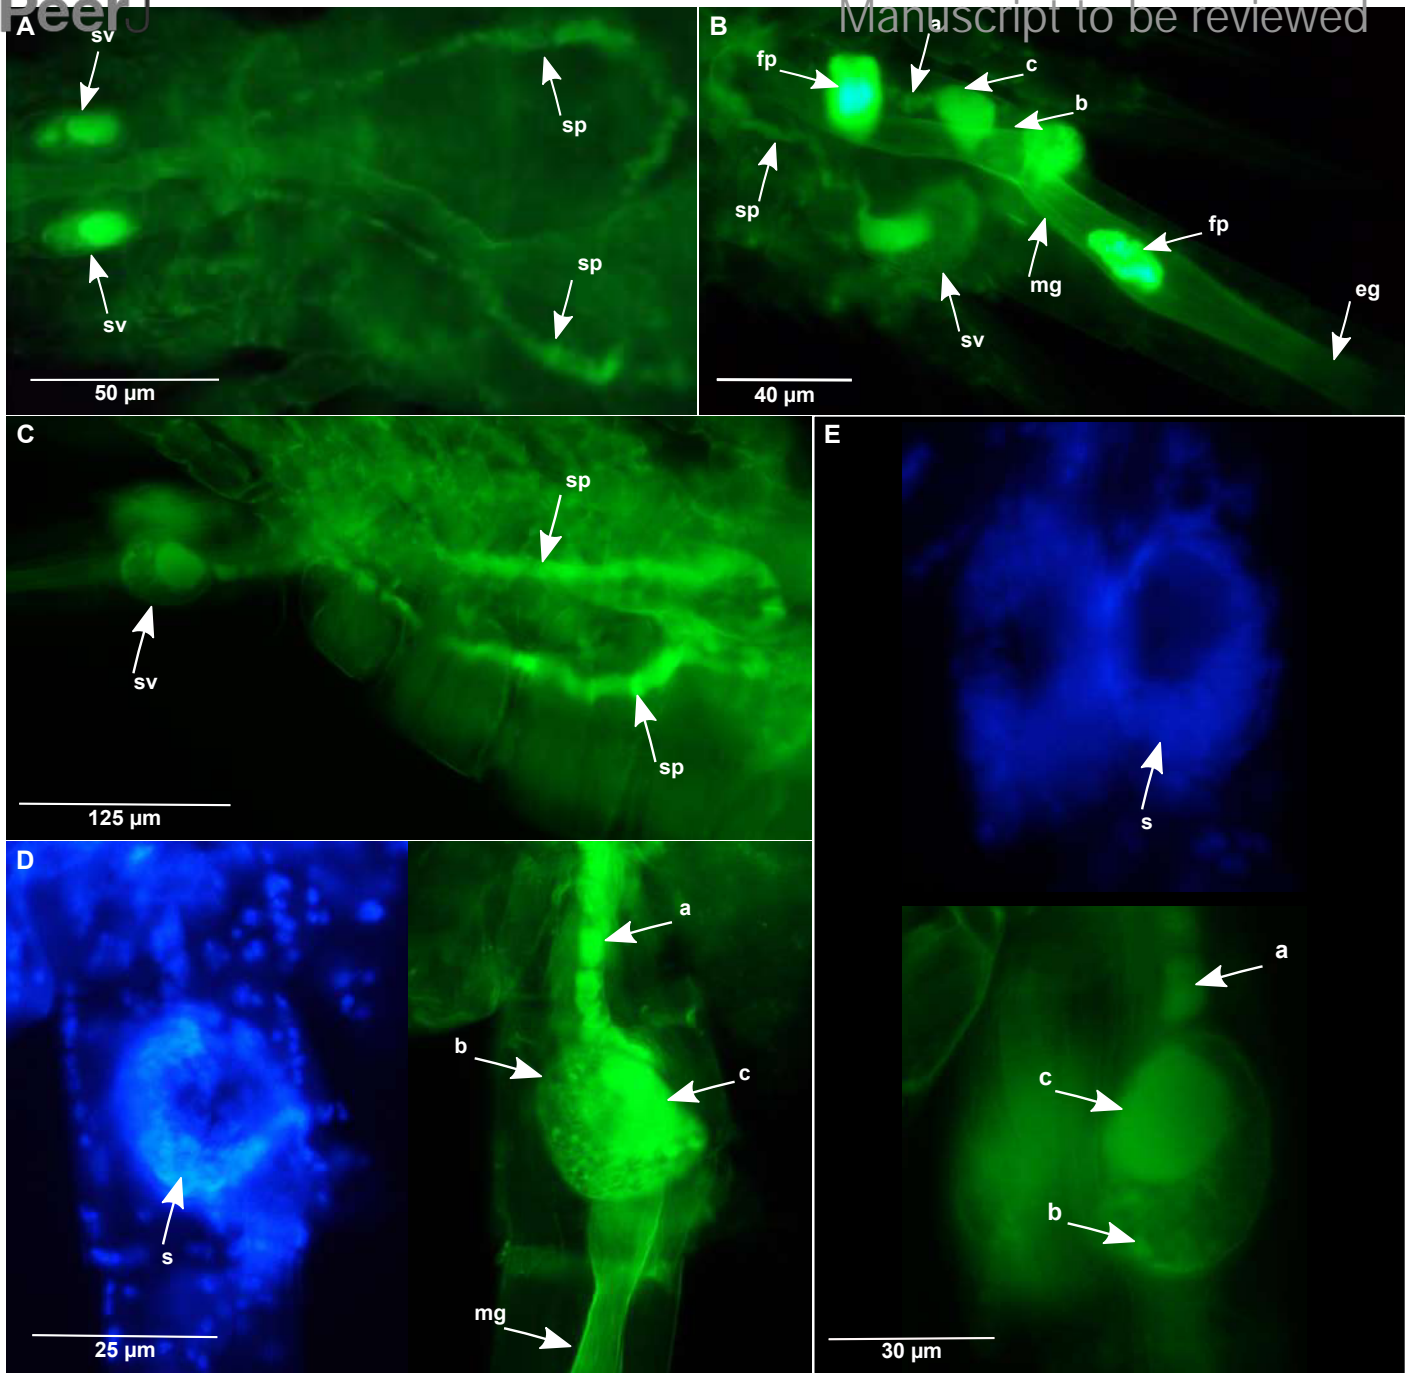

**mg**: midgut, **sr**: seminal receptacle, **s**: semen, **ov**: oviduct, **hg**: hindgut, **b**: diffuse chitin region, **c**: chitin rich region. **A-B**.. Dorsal view of the *O.nana* female reproductive system (DAPI staining on the left and WGA-FITC staining on the right). **C-D**. Dorsal view of the *O. similis* female reproductive system (DAPI staining on the left and WGA-FITC staining on the right). **E-F**. Dorsal view of the *O. nana* female double sexual somite (DAPI staining on the left and WGA-FITC staining on the right).

# Figure 4(on next page)

*Oithona* male reproductive system by DAPI and WGA-FITC fluorescence microscopy.

**mg**: midgut, **fp**: fecal pellet, **sv**: seminal vesicle, **sp**: spermiduct, **a**: heterogeneous chitin, **b**: diffuse chitin, **c**: chitin rich region. **A**. Dorsal view of the *O.nana* male reproductive system. **B**. Dorso-lateral view of the *O.nana* seminal vesicle. **C**. Lateral view of the male *O.similis* reproductive system. **D**. Lateral view of the *O.nana* male double sexual somite. **E**. Lateral view of the *O.similis* male double sexual somite.

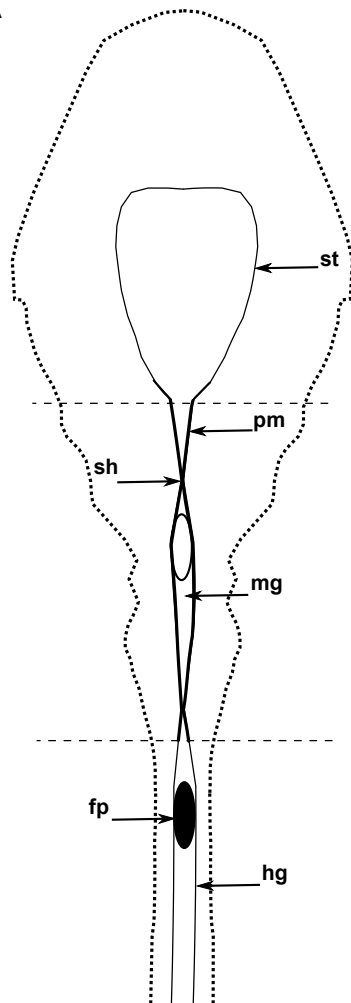

# Figure 5(on next page)

The diagram of the internal anatomy of a female *Oithona nana*.

**st**: stomach, **mg**: midgut, **pm**: peritrophic membrane, **go**: gonads, **sh**: shrinkages, **fp**: fecal pellet, **hg**: hindgut, **sr**: seminal receptacle, **ov**: oviduct. Thick black zones correspond to chitin rich areas. Dark gray zones correspond to heterogeneous chitin area. Light grey zones correspond to amorphous chitin areas. **A**. Diagram of the dorsal view of the digestive system. **B**. Diagram of the dorsal view of the reproductive system.
