The seed oil of *Jatropha curcas* is considered a potential bioenergy source that could replace fossil fuels. However, the seed yield of *Jatropha* is low and has yet to be improved. We previously reported that exogenous cytokinin treatment increased the seed yield of *Jatropha*. Cytokinin levels are directly regulated by isopentenyl transferases (IPT), cytochrome P450 monooxygenase (CYP735A) and cytokinin oxidase/dehydrogenase (CKX). In this study, we cloned six *IPT* genes, one *JcCYP735A* gene, and seven *JcCKX* genes. The expression patterns of these 14 genes in various organs were determined using real-time quantitative PCR. *JcIPT1* was primarily expressed in roots and seeds, *JcIPT2* was expressed in roots, apical meristems, and mature leaves, *JcIPT3* was expressed in stems and mature leaves, *JcIPT5* was expressed in roots and mature leaves, *JcIPT6* was expressed in seeds at 10 days after pollination, and *JcIPT9* was expressed in mature leaves. *JcCYP735A* was mainly expressed in roots, flower buds, and seeds. The seven *JcCKX* genes also showed different expression patterns in different organs of *Jatropha*. In addition, CK levels were detected in flower buds and seeds at different stages of development. The concentration of iP, iPR and tZ increased with flower development, and the concentration of iP decreased with seed development, while that of tZ increased. We further analyzed the function of *JcCYP735A* using the CRISPR-Cas9 system, and found that the concentrations of tZ and tZR decreased significantly in the *Jccyp735a* mutants, which showed severely retarded growth. These findings will be helpful for further studies of the functions of cytokinin metabolic genes and understanding the roles of cytokinins in *Jatropha* growth and development.

ABSTRACT

The seed oil of *Jatropha curcas* is considered a potential bioenergy source that could replace fossil fuels. However, the seed yield of *Jatropha* is low and has yet to be improved. We previously reported that exogenous cytokinin treatment increased the seed yield of *Jatropha*. Cytokinin levels are directly regulated by isopentenyl transferases (IPT), cytochrome P450 monooxygenase (CYP735A) and cytokinin oxidase/dehydrogenase (CKX). In this study, we cloned six *IPT* genes, one *JcCYP735A* gene, and seven *JcCKX* genes. The expression patterns of these 14 genes in various organs were determined using real-time quantitative PCR. *JcIPT1* was primarily expressed in roots and seeds, *JcIPT2* was expressed in roots, apical meristems, and mature leaves, *JcIPT3* was expressed in stems and mature leaves, *JcIPT5* was expressed in roots and mature leaves, *JcIPT6* was expressed in seeds at 10 days after pollination, and *JcIPT9* was expressed in mature leaves. *JcCYP735A* was mainly expressed in roots, flower buds, and seeds. The seven *JcCKX* genes also showed different expression patterns in different organs of *Jatropha*. In addition, CK levels were detected in flower buds and seeds at different stages of development. The concentration of iP, iPR and tZ increased with flower development, and the concentration of iP decreased with seed development, while that of tZ increased. We further analyzed the function of *JcCYP735A* using the CRISPR-Cas9 system, and found that the concentrations of tZ and tZR decreased significantly in the *Jccyp735a* mutants, which showed severely retarded growth. These findings will be helpful for further studies of the functions of cytokinin metabolic genes and understanding the roles of cytokinins in *Jatropha* growth and development.

42

43 INTRODUCTION

44 *Jatropha curcas* is a multipurpose tree that belongs to the Euphorbiaceae family. It can endure
 45 drought and adapt to barren land in tropical and subtropical regions. *Jatropha* is considered a
 46 promising biofuel plant due to the high oil content in its seeds (Akashi 2012; Francis et al. 2005;
 47 Makkar & Becker 2009). However, the seed yield is very low, potentially because of the
 48 relatively low number of total flowers and/or the ratio of female to male flowers in *Jatropha*
 49 (Kumar & Sharma 2008; Kumar Tiwari et al. 2007; Rao et al. 2008). Recently, several studies
 50 have reported that exogenous cytokinin (CK) treatment can significantly increase the total
 51 number of flowers per inflorescence, the female-to-male flower ratio, and the seed yield
 52 (Fröschle et al. 2017; Pan & Xu 2011).

53 CKs are important hormones in plants and participate in many biological processes, such as
 54 apical dominance (Shimizu-Sato et al. 2009; Tanaka et al. 2006), root proliferation (Kudo et al.
 55 2010; Werner et al. 2003), reproductive development (Ashikari et al. 2005), and senescence (Gan
 56 & Amasino 1995). Endogenous CKs containing N⁶-(Δ²- isopentenyl)-adenine (iP), *trans*-zeatin
 57 (tZ), *cis*-zeatin (cZ), dihydrozeatin (DZ), and their conjugates are known as isoprenoid CKs
 58 (Mok & Mok 2001). The major derivatives are generally iP- and tZ-type CKs (Sakakibara 2006).

59 CK biosynthesis and degradation pathways have been well studied in the past decade (Figure 1)
 60 (Galuszka et al. 2007; Kudo et al. 2010; Sakakibara 2006). The first step of iP and tZ
 61 biosynthesis is catalysed by adenosine phosphate-isopentenyltransferases (IPTs). IPTs produce
 62 iP-ribotides from dimethylallyl diphosphate (DMAPP) and adenosine 5'-diphosphate (ADP) or
 63 adenosine 5'-triphosphate (ATP) (Ihara et al. 1984; Taya et al. 1978). iP-ribotides can then be
 64 hydroxylated to tZ-ribotides by cytochrome P450 monooxygenase (CYP735A) (Takei et al.
 65 2004). These cytokinin ribotides are converted to free-base CKs by cytokinin-activating enzymes
 66 LONELY GUYS (LOGs) (Kurakawa et al. 2007; Kuroha et al. 2009; Tokunaga et al. 2012). In
 67 addition, cZ and tZ can be enzymatically interconverted by zeatin *cis-trans* isomerase (Bassil et
 68 al. 1993; Sakakibara 2006). In *Arabidopsis*, IPT1 and IPT3 to IPT8 are involved in iP and tZ
 69 biosynthesis (Kakimoto 2001; Sun et al. 2003; Takei et al. 2001), while IPT2 and IPT9 are
 70 involved in cZ biosynthesis (Golovko et al. 2002). *CYP735A1* is abundant in roots and flowers in

Arabidopsis, while *CYP735A2* specifically accumulates in roots (Takei et al. 2004). *CYP735As* are required for shoot growth (Kiba et al. 2013). Cytokinin oxidase/dehydrogenase (CKX) catalyses the irreversible degradation of CKs (Galuszka et al. 2001; Galuszka et al. 2007; Schmulling et al. 2003). *CKXs* play important roles in controlling CK levels in plant tissues. In *Arabidopsis*, *CKX3* and *CKX5* regulate the activity of reproductive meristems (Bartrina et al. 2011). In rice, *OsCKX4* mediates crown root development by integrating cytokinin and auxin signalling (Gao et al. 2014).

CKs play important roles in flower bud development and floral sex differentiation (Chandler 2011; Gerashchenkov & Rozhnova 2013; Yamasaki et al. 2005). However, the roles of CK biosynthesis genes *IPTs* and *CYP735A* and catabolism gene *CKXs* in *Jatropha* are not clear. In this study, we isolated sequences of cytokinin metabolic genes, including 6 *IPTs*, one *JcCYP735A* and 7 *JcCKXs*, using the *Jatropha* Genome Database (Hirakawa et al. 2012; Sato et al. 2010; Wu et al. 2015). The 14 genes showed different expression patterns in different tissues of *Jatropha*. Some of them exhibited tissue-specific expression. *JcIPT6* was only expressed in seeds a few days after pollination. *JcCYP735A* was highly expressed in roots and seeds. *JcCKX4* was expressed mainly in seeds. In addition, CK types and contents were detected in flower buds and seeds. With flower bud development iP-type CKs increased, while tZ-type CKs decreased. With seed development, tZ-type CKs increased, while iP-type CKs decreased. The *Jccyp735a* mutants were obtained by the clustered regularly interspaced short palindromic repeats (CRISPR)-Cas9 system. Compared with the wild-type (WT) plants, the concentrations of tZ and tZR decreased significantly in the *Jccyp735a* mutants, which showed severely retarded growth. These results will be helpful for future studies of the functions of these genes and for improving the biological characteristics of *Jatropha*.

MATERIALS & METHODS

Plant materials and growth conditions

Three-year-old *Jatropha* trees were grown in the field at Xishuangbanna Tropical Botanical Garden of the Chinese Academy of Sciences, Mengla County, Yunnan Province, China (21°54' N, 101°46' E; 580 m in altitude). The seedlings of WT and the T1 plants of *Jccyp735a* mutants were grown in the greenhouse (28°C, 12 h light/ 12 h dark, 70% humidity). Flower buds, ovules,

and seeds at different developmental stages were collected in May to July 2015 for qRT-PCR analysis of *JcIPT6* expression and quantification of cytokinin contents. All other samples used in qRT-PCR experiments were collected at the same time in May 2015. Various plant tissue samples, including lateral roots of 1-2 mm in diameter with fine-roots and root tips, shoot apex of 0.3 cm in length from the top of shoots, stems of 1.5 cm in diameter, young leaf blades of 2 cm in length, mature leaf blades of 15 cm in length, flower buds of 0.3 cm in length, just-opened female and male flowers, fruits of 15 days after pollination, and seeds of 30 days after pollination, were harvested for qRT-PCR analysis. All tissues were immediately frozen in liquid nitrogen and stored at -80°C until needed.

Gene identification and isolation

Sequences of orthologous *IPT*, *CYP735A* and *CKX* genes from *Arabidopsis* that were available in the GenBank database were used as query sequences for BLAST analysis using GenBank, the *Jatropha* Genome Database (<http://www.kazusa.or.jp/Jatropha/index.html>) and our *Jatropha* transcriptome data (Chen et al. 2014; Pan et al. 2014). The full length of complementary DNA (cDNA) and genomic DNA sequences of the *JcIPT*, *JcCYP735A*, and the *JcCKX* genes were obtained by PCR amplification. The PCR products were subsequently cloned into the pGEM-T vector (Promega Corporation, Madison, WI, United States) and sequenced. The GenBank accession numbers for the nucleotide sequences of these genes are listed in Table S1. Primers used in PCR are listed in Table S2.

Sequence comparison and phylogenetic analysis

Sequence chromatograms were examined and edited using Chromas Version 2.23 (<http://technelysium.com.au/>). Related sequences were identified with BLAST (<http://www.ncbi.nlm.nih.gov/BLAST/>). A phylogenetic tree was generated with MEGA 7.0 (<http://www.megasoftware.net/>) using the Poisson model with gamma-distributed rates and 1000 bootstrap replicates.

Expression pattern analysis by qRT-PCR

Total RNA was extracted from each tissue, and first-strand cDNA was synthesized with a PrimeScript® RT Reagent Kit with gDNA Eraser (Takara, Dalian, China) according to the manufacturer's instructions. qRT-PCR was performed with LightCycler® 480 SYBR Green I

Master (Roche) on the Roche 480 Real-Time PCR Detection System (Roche Diagnostics). qRT-PCR was performed with two independent biological replicates (tissue samples were harvested from different plants) and three technical replicates for each sample. Data were analysed using the $2^{-\Delta\Delta CT}$ method as described by Livak and Schmittgen (Livak & Schmittgen 2001). Expression levels of specific genes were normalized to that of the *actin* gene in *Jatropha* (Zhang et al. 2013). Primers used in qRT-PCR are listed in Table S3.

Quantification of cytokinin

Cytokinin contents were determined by the Wuhan Greensword Creation Technology Co. Ltd., using a polymer monolith microextraction coupled with hydrophilic interaction chromatography-tandem mass spectrometry method as described previously (Liu et al. 2010). The leaves used to quantify the CKs were the third and fourth new leaves from four-month-old WT and the T1 plants of *Jccyp735a* mutants. Three independent biological replicates and three technical replicates were measured for each sample. The data were analyzed using the Statistical Product and Service Solutions software (SPSS Inc., Chicago, IL, USA, version 16.0). Differences among the means were determined using a one-way ANOVA with Tukey's or Tamhane's post hoc tests ($p < 0.05$).

Construction of CRISPR/Cas9 vectors and transformation of *Jatropha*

The sequence of *JcCYP735A* (GenBank accession no. XM_012222581.2) was analyzed with the online tool CRISPR-P (<http://cbi.hzau.edu.cn/crispr/>) to find the target sites of CRISPR/Cas9. pYLsgRNA-AtU3d/LacZ (GenBank accession no. KR029100) as the single-guide RNA (sgRNA) intermediate plasmid, and pYLCRISPR/Cas9P_{35S}-N (GenBank accession no. KR029112) as the binary vector were used for the CRISPR-Cas9 construction of *JcCYP735A* following the instruction of the CRISPR-Cas9 System (Ma et al. 2015). Transformation of *Jatropha* with *Agrobacterium* strain EHA105 carrying the *JcCYP735A* CRISPR/Cas9 construction was performed according to the protocol described by Fu et al. (2015). The *Jccyp735a* mutants in transgenic *Jatropha* plants were identified by PCR amplification and DNA sequencing using a pair of primers, XB619 (5'-ATGGCCATGATATTAACAACCTCTATTAG-3') and XB620 (5'-GCGGTTCTATCCCATTCCAGTATAT-3').

RESULTS

Cloning and identification of *JcIPTs*, *JcCYP735A*, and *JcCKXs*

Using all annotated *Arabidopsis* IPT, CYP735A and CKX family members in the TAIR as query sequences to perform a BLAST analysis in GenBank and with our *Jatropha* transcriptome data (Chen et al. 2014; Pan et al. 2014), we identified and cloned *IPT*, *CYP735A* and *CKX* orthologous sequences in *Jatropha*. The *Jatropha IPT* family included only six members, while there are nine members in *Arabidopsis*. These genes were named *JcIPT1*, *JcIPT2*, *JcIPT3*, *JcIPT5*, *JcIPT6*, and *JcIPT9*. The BLAST analysis identified only one member of the *CYP735A* family, *JcCYP735A*. The *CKX* gene family, encoding degradation enzymes, included the same seven members in *Jatropha* as in *Arabidopsis*. These genes were named *JcCKX1*, *JcCKX2*, *JcCKX3*, *JcCKX4*, *JcCKX5*, *JcCKX6*, and *JcCKX7*.

Sequence structure analysis showed that *IPT*, *CYP735A*, and *CKX* family members shared almost the same numbers of exons and introns between *Jatropha* and *Arabidopsis* and had similar exon lengths (Figure 2, 3). *JcIPT6* has two more exons than *IPT6* from *Arabidopsis*. However, the extra two exon sequences are short and are not part of the P-loop NTPase domain (Figure 2a).

Phylogenetic analysis of *JcIPTs*, *JcCYP735A*, and *JcCKXs*

To analyse the phylogenetic relationships between orthologous genes, phylogenetic analysis were performed. IPT, CYP735A and CKX family members from *Arabidopsis thaliana*, *Ricinus communis*, and *Oryza sativa* were compared with those from *Jatropha*. Orthologues of IPT1, 2, 3, 5, and 7 formed a clade, while IPT9 formed a single clade (Figure 4a). *JcCYP735A* along with other dicotyledon CYP735As formed a clade, while CYP735A3 and 4 of *Oryza sativa* formed another clade (Figure 4b). Orthologues of CKX1, 5, 6, and 7 formed a clade, while those of CKX2, 3, and 4 formed a separate clade (Figure 5). These results showed that *JcIPTs*, *JcCYP735A*, and *JcCKXs* were most closely related to genes from *Ricinus communis*, which also belongs to the Euphorbiaceae family.

Expression patterns of *JcIPTs*, *JcCYP735A*, and *JcCKXs* in different tissues

In order to gain more information of these gene family members in *Jatropha*, the temporal and spatial expression patterns of these genes were analysed using qRT-PCR. *JcIPT1* was mainly expressed in roots (Figure 6a). *JcIPT2* was mainly expressed in roots, shoot apical meristems,

mature leaves, and flower buds (Figure 6b). *JcIPT3* showed much higher expression levels in stems and mature leaves than other tissues (Figure 6c). *JcIPT5* exhibited high expression levels in roots and mature leaves (Figure 6d). *JcIPT9* only showed high expression levels in mature leaves (Figure 6f). The expression of *JcIPT6* was not detected in most of the plant tissues indicated above. After analysing more tissues (Figure S1), we found that *JcIPT6* began to be expressed in seeds a few days after fertilization, with the strongest expression observed in seeds at 10 days after fertilization; the expression levels then decreased rapidly. In seeds at 20 days after fertilization, *JcIPT6* expression decreased by a factor of 5 compared with seeds at 10 days after fertilization (Figure 6e). The expression levels of *JcCYP735A* were higher in roots, flower buds, and seeds than other tissues (Figure 7a). *JcCKX1* was mainly expressed in flower buds, roots, and female flowers (Figure 7b). *JcCKX2* showed very strong expression in female flowers and seeds (Figure 7c). *JcCKX3* was highly expressed in male flowers (Figure 7d). *JcCKX4* exhibited high expression levels in mature leaves and extremely high expression in seeds (Figure 7e). *JcCKX5* was mainly expressed in stems, young leaves, and fruit (Figure 7f). *JcCKX6* was expressed in all tissues (Figure 7g). *JcCKX7* was mainly expressed in roots (Figure 7h).

Endogenous CK contents in flower buds and seeds

In order to learn more about the distribution of endogenous cytokinins, we measured the contents of endogenous CKs in *Jatropha* flower buds and seeds at different developmental stages (Figure S1). Different profiles were observed for each CK variant with flower bud and seed development in *Jatropha* (Table 1). The contents of iP and its variant iPR increased approximately 177-fold and 9-fold, respectively, from the flower bud 1 (FB1) stage to the flower bud 2 (FB2) stage. Compared with the FB1 stage, tZ content was approximately doubled in the FB2 stage, while tZR content was reduced by 93%, resulting in a decrease in the amount of total active tZ variants. Conversely, the contents of tZ variants increased remarkably during seed development; compared with ovules, the tZ content increased 187-fold and the tZR content increased 496-fold in seeds at 20 DAP.

***Jccyp735a* mutants generated by CRISPR-Cas9 system showed retarded growth**

To explore the biological function of *JcCYP735A* in *Jatropha*, we generated *Jatropha* transformants with *JcCYP735A* knocked out using the CRISPR-Cas9 system (Figure 8). Three homozygous mutant lines, L1, L2, and L3, were obtained by DNA sequencing (Figure 8a).

Endogenous contents of CKs in the leaves of two lines of *Jccyp735a* mutants (L2 and L3) and WT plants were examined. The results showed that the concentrations of tZ and tZR, and cZ and cZR significantly decreased, whereas the concentrations of iP and iPR significantly increased in *Jccyp735a* mutants compared with that of the WT (Figure 8b). *Jccyp735a* mutants showed severely retarded growth, and the mutant plants were only approximately a quarter the height of the WT plants (Figure 8c and d).

DISCUSSION

In our study, six *IPT* family members were identified in *Jatropha*. The number of *IPT* genes differs among plant species; for example, there are six *IPTs* in *Ricinus communis*, while there are nine *IPTs* in both *Arabidopsis* (Kakimoto 2001; Takei et al. 2001) and rice (Figure 4a). *JcIPTs* have the same number of exons as those in *Arabidopsis*, except *JcIPT6*, which has two more exons than *AtIPT6*. The third exon of *JcIPT6* has almost the same number of base pairs as the only exon in *AtIPT6* (Figure 2a). It appears that the other two small exons were lost during evolution. Expression pattern analysis revealed that different *JcIPT* members are expressed in different tissues in *Jatropha* (Figure 6). *JcIPT1* had an expression pattern similar to that of *AtIPT1* and was mostly expressed in roots, shoot apical meristems, and seeds (Miyawaki et al. 2004). *JcIPT2* and *JcIPT9* were assigned to the same cluster as their orthologues (Figure 4a). In *Arabidopsis*, *AtIPT2* and *AtIPT9* are expressed ubiquitously, with stronger expression in proliferating tissues, including the root and shoot apical meristems and leaf primordia (Miyawaki et al. 2004). Similarly, *JcIPT2* and *JcIPT9* were expressed ubiquitously in *Jatropha*. However, the strongest expression of both was in mature leaves instead of meristems and young leaves (Figure 6b, f). Considering that *AtIPT2* and *AtIPT9* are tRNA-IPTs, which only catalyse cZ biosynthesis (Golovko et al. 2002), cZ might be produced mainly in mature leaves of *Jatropha*. *AtIPT3* was found to be responsible for nitrate-dependent cytokinin biosynthesis and is predominantly expressed in the phloem (Miyawaki et al. 2004; Takei et al. 2002). In our study, *JcIPT3* was strongly expressed in stems and mature leaves, which contain abundant phloem (Figure 6c). A study by Miyawaki et al. (2004) showed that GUS activity is not detected in *Arabidopsis* transformants carrying *AtIPT6::GUS*. RT-PCR analysis indicated that it was abundant in siliques. Analogously, we did not detect *JcIPT6* in most tissues of *Jatropha*, including fruits. We found that *JcIPT6* was mainly expressed in seeds at 10 days after

pollination, and its expression decreased rapidly thereafter (Figure 6e). It is possible that the previous study missed this critical phase in the seeds chosen for GUS staining (Miyawaki et al. 2004). Our results suggested that different *JcIPT* family members play different roles in the development of *Jatropha* and that some *JcIPT* members could be used to cultivate high-yield varieties of *Jatropha* using transgenic technology.

Although none of the ATP/ADP *JcIPTs* were found to be highly expressed in flowers, iP, iPR, and tZ contents increased with the development of flower buds (Table 1). It is known that CKs can be transported through the plant vascular system (Hirose et al. 2007). *JcCYP735A* was found to be highly expressed in flower buds (Figure 7a). iP-type CKs may be transported into flowers, and some may then be used to generate tZ-type CKs via *JcCYP735A*. In addition, it has been reported that the tZ concentration is up-regulated in the early development of tomato fruits (Matsuo et al. 2012). Our study showed that *JcCYP735A* was highly expressed and that the tZ concentration increased with seed development in *Jatropha* (Table 1). Thus, *JcCYP735A* might play important roles in seed development by controlling tZ biosynthesis. Similar to *Ricinus communis* (Chan et al. 2010), only one *CYP735A* gene was found in *Jatropha*, although there are two *CYP735A* members in *Arabidopsis* and rice (Takei et al. 2004; Tsai et al. 2012).

Unlike *JcIPT* or *JcCYP735A* family, the *JcCKX* family in *Jatropha* has the same number of members as that in *Arabidopsis* (Figure 3). In addition, the *JcCKX* and *AtCKX* orthologues contain the same number of exons, with 5 exons in *CKX1-6* and 4 exons in *CKX7* (Figure 3). Further expression analysis showed that *JcCKX2* was mostly expressed in female flowers, whereas *JcCKX3* was mostly expressed in male flowers (Figure 7c, d). Both *JcCKX2* and *JcCKX4* were expressed strongly in seeds (Figure 7c, e). These tissue-specific expression genes may be chosen to adjust the CK content in these tissues using transgenic methods. It has been reported that reduced expression of *OsCKX2* causes cytokinin accumulation in inflorescence meristems and increases the number of reproductive organs, resulting in enhanced grain yield (Ashikari et al. 2005). Decreased expression of *CKX* orthologues may also lead to increased yield in *Jatropha*. Moreover, overexpression of some *CKX* members can also improve resistance. Overexpression of *CKX1* or *CKX2* in *Arabidopsis* and other species causes elongation of the primary root and increases root branching (Galuszka et al. 2004; Mrízová et al. 2013; Pospisilova et al. 2016; Werner et al. 2001; Yang et al. 2003), while overexpression of *AtCKX7* results in an

opposite phenotype (Kollmer et al. 2014). Specific expression of *JcCKX1* or *JcCKX2* in roots might be used to transform a shallow root system into a deep root system to improve the growth and lodging resistance of *Jatropha*. Furthermore, root system development might enhance tolerance to drought stress. Remarkably, *JcCKX4* expression was much higher in seeds than other tissues (Figure 7e), suggesting that *JcCKX4* may be a key enzyme regulating cytokinin levels to affect seed development.

In early flower bud development, the content of iP-type CKs increased significantly, while that of tZ-type CKs decreased. This result indicated that iP-type CKs participate more in early flower bud development than tZ-type CKs. In tomato, iP-type CK contents decrease during fruit ripening (Matsuo et al. 2012). By contrast, in early seed development, the content of tZ-type CKs increased substantially, while that of iP-type CKs decreased. This result, which is in accordance with high expression of *JcCYP735A* in seeds, suggested that tZ-type CKs are dominant in early seed development. Many differences were observed in CK contents in different periods of *Jatropha* flower bud and seed development. Our results indicate that iP-type CKs can be used to improve the number of flowers in *Jatropha*, while tZ-type CKs can be used to enlarge seeds.

The single *cyp735a1* or *cyp735a2* mutant *Arabidopsis* showed slight decreases in tZ and tZR concentration compared with that of WT, while the double mutants showed great decreases (Kiba et al. 2013). In addition, *cyp735a1 cyp735a2* double mutants exhibited retarded shoot growth (Kiba et al. 2013). Similarly, in this study, *Jccyp735a* mutants showed substantial decreases in tZ and tZR concentrations (Figure 8b), which is consistent with that only a single member of *JcCYP735A* was found in *Jatropha* genome (Wu et al. 2015). We noticed, however, tZ and tZR did not completely disappear in *Jccyp735a* mutants (Figure 8b), which may result from conversion of cZ and cZR. This notion is supported by the fact that the concentrations of cZ and cZR also significantly decreased in *Jccyp735a* mutants (Figure 8b), and that *cis-trans* isomerase activity for interconversion between cZ-type and tZ-type CKs has been reported in several plant species (Bassil et al. 1993; Kudo et al. 2012; Suttle & Banowitz 2000).

CONCLUSIONS

In this study, we isolated the members of the *JcIPT*, *JcCYP735A* and *JcCKX* gene families and analysed their temporal and spatial expression patterns. Different family members exhibited different expression patterns. Different types of CKs seemed to influence the development of

flower buds and seeds, respectively. The analysis of the *Jccyp735a* mutants revealed that *JcCYP735A* plays an important role in tZ biosynthesis in *Jatropha*. These results will be helpful for further function studies of cytokinin metabolic genes and improving agronomic characteristics of *Jatropha* by genetic engineering of cytokinin metabolism.

ACKNOWLEDGMENTS

We thank Prof. Yao-Guang Liu (South China Agricultural University, China) for providing vectors pYLCRISPR/Cas9P_{35S}-N and pYLsgRNA-AtU3d. The authors gratefully acknowledge the Central Laboratory of the Xishuangbanna Tropical Botanical Garden for providing research facilities.

Abbreviations

BLAST	basic local alignment search tool
CK	cytokinin
CKX	cytokinin oxidase/dehydrogenase
CRISPR	clustered regularly interspaced short palindromic repeats
CYP735A	cytochrome P450 monooxygenase, family 735, subfamily A
cZ	<i>cis</i> -zeatin
DZ	dihydrozeatin
DZR	dihydrozeatin-riboside
iP	N6-(Δ^2 - isopentenyl)-adenine
IP9G	N6-(Δ^2 - isopentenyl)-adenine-9-glucoside
iPR	iP-riboside
IPT	adenosine phosphate-isopentenyltransferases
LOG	LONELY GUY
qRT-PCR	quantitative reverse transcriptase-polymerase chain reaction
tZ	<i>trans</i> -zeatin
tZ9G	<i>trans</i> -zeatin-9-glucoside
tZR	tZ-riboside
