8 **Abstract**

9 **Background.** Egg size and clutch size are the key life history traits. It is possible

10 during the breeding period to increase the fitness of the offspring either by increasing the
11 number of eggs if the optimal egg size (OES) is maintained, or by increasing the allocation of
12 energy to each egg. However, the strategies adopted by animals are deeply often influenced by
13 their morphology and environment, or both.

14 **Methods.** In this paper, we studied variation of female morphological traits and reproductive
15 traits, the test for an egg size-number clutch size trade-off, and the relationship between egg
16 size and female morphology in three populations of *Phrynocephalus helioscopus*.

17 **Results.** In both the Yi Ning and Fu Yun populations, female body size, egg size, and clutch
18 size were larger in the Yi Ning and Fu Yun populations than that of the Bei Tun population
19 (so the reproductive output of the Bei Tun females was the smallest, and both the Fu Yun
20 and Yi Ning populations had laid more, and rounder eggs). Egg size was not constrained by
21 female body size in the Beitun and Fuyun populations, but there were egg size-number clutch
22 size trade-offs occurred in both populations. Egg size-number clutch size trade-offs were not
23 present found in the Yining population, but egg size was correlated to with female body size,

Future reproductive value? This is not necessarily true – that is, it is NOT increasing the fitness of the offspring, but rather increasing fitness of the female laying the eggs!

Unknown Author

Here we examine

Unknown Author
06/21/2018 10:55

24 consistent with the hypothesis of morphological constraint.

25 **Conclusions.** Our study found **geographic** variation in body size and reproductive strategies of
26 the lizard *Phrynocephalus helioscopus*. Egg size **was correlated with** morphology in the
27 larger-bodied females of the YN population but not in the small-bodied females of the BT
28 population, ~~suggesting~~ illustrating that constraints on female body size ~~specific constraints on~~
29 and egg size ~~in smaller-bodied females does do~~ not always occur.

30 1. Background

31 Animals often exhibit variation in reproductive traits as a result of differences in the
32 quality of resources and food availability of different habitats (Roff, 2002; Cruz-Elizalde &
33 Ramirez-Bautista, 2016). Egg size and number are the key life history traits, and have
34 received more attention than other reproductive traits (**Qu et al., 2011; Amat 2008; Lovich**
35 **et al., 2012**). **When food is less available** ~~city is poor~~, females may face the problem of having
36 ~~to allocate insufficient~~ **limited reproductive resources to invest in eggs, which results in a**
37 **trade-off** between 1) the energy allocated to each egg (egg size), and 2) the
38 **total** number of eggs (clutch size, CS). An increase in resources ~~allocation~~ **ed** to each egg will
39 ~~come at the cost of~~ **result in** decreasing CS (Roff, 1992; Kaplan & Phillips, 2006).
40 ~~In addition, a~~ **This negative relationship between egg size and clutch size provides evidence**
41 **of reproductive trade-offs (Rowe 1992), and** variations in reproductive output from different
42 populations **sometimes** are **correlated with varying relationships** between egg size and
43 ~~number~~ **clutch size** (Thompson & Pianka, 2001).-▲

44 Variation in female reproductive output ~~is are~~ **widespread, and exist not only both**
45 interspecifically ~~but also~~ **and** intraspecifically. Especially for ~~some ubiquitous~~ **widespread**

A consequence of this trade-off.

Unknown Author
06/21/2018 11:28

You're being redundant here, basically repeating the idea of egg size – clutch size tradeoff without adding information.

Unknown Author
06/21/2018 11:27

46 | species, local genetic variation ~~brought about by environmental factors~~, short-term
47 | phenotypic plasticity, and the complex interactions between these
48 | two, ~~all~~ contribute to ~~those~~ variation in reproductive output (Brown & shine,
49 | 2007).

50 | Optimal egg size (OES) theory predicts that natural selection optimizes egg size within
51 | populations, ~~thus such that~~ when ~~sufficient~~ resources are available (not limiting) for
52 | reproduction, clutch size or number of clutches may increase, ~~females may have larger CS~~
53 | ~~(or more clutches)~~ rather than an increase in larger egg size (Smith & Fretwell, 1974;
54 | Brockelman, 1975). Natural selection predicts that females should optimize resources
55 | allocated to each egg, and CS should only increase ~~CS~~ after ensuring the production of high-
56 | quality offspring ~~fitness~~ (Lovich *et al.*, 2012). In some reptiles, CS is positively correlated
57 | with ~~the maternal~~ female morphological traits, ~~but while~~ egg size is not, consistent with OES
58 | theory (Congdon & Gibbons, 1987). However, the relationship between egg size and number
59 | is determined by numerous factors, and the trade-offs between egg size and number are not
60 | always evident in natural populations (Berven, 1982; Liao & Lu, 2011; Wang
61 | *et al.*, 2011).

62 | In some reptiles, ~~especially in some turtles~~, egg size is corelated ~~to with female maternal~~
63 | body size (morphological constraint hypothesis), and both egg size and number increase with
64 | an increase in ~~maternal~~ female body size, contrary to OES theory (Dunham & Miles, 1985;
65 | Clark, Ewert & Nelson, 2001; Mohamed *et al.*, 2012; Ryan & Lindeman, 2007).
66 | This type of eConstraints between ~~female maternal~~ morphological traits and egg size (e.g.,
67 | egg width being constrained by the pelvic aperture width in some turtles and lizards) results

This paragraph only has two sentences, and could be joined to the following or the previous.

Unknown Author
06/21/2018 11:29

68 in ~~lack of fit with some species not conforming to~~ predictions ~~off~~from OES theory. ~~Especially~~
69 ~~When~~ resources are limited, reproductive output is directly correlated with the trade-offs
70 between egg size and ~~number~~clutch size, and ultimately with the ~~future~~offspring survival
71 ~~of the population as well~~ (Brown & Shine, 2009; Congdon & Tinkle, 1982). The size of each
72 egg normally determines the success of incubation and ~~the~~offspring's survival (Angilletta
73 *et al.*, 2004; Räsänen, Laurila & Merilä, 2005). Females may allocate more energy to
74 individual eggs, aiming for ~~higher fitness~~greater survival of their offspring.

Not necessarily, because
eggs can still be smaller
when resources are
limiting.

Unknown Author
06/21/2018 11:36

75 *Phrynocephalus helioscopus* is a small (mean SVL 47.55mm) lizard that is widely
76 distributed in Eurasia. Previous research on this species has focused on egg incubation (Wang
77 *et al.*, 2013) and female reproductive output (Liang *et al.*, 2015). However, among the
78 distinct populations of this widely distributed species, ~~neither variation in the female~~
79 ~~reproductive traits and the egg size-number trade-off, nor the effects of~~
80 ~~maternal~~female morphological traits on egg size have been studied. In this study, we
81 compared ~~maternal~~female morphological traits ~~and the relationships among~~
82 ~~their~~, egg length (EL), egg width (EW), egg mass (EM), egg shape (ES) and
83 ~~clutch size (CS) in~~among three populations. ~~Specifically, and examined the relationship of~~
84 ~~female morphological traits on egg size and CS with an aim~~
85 ~~toward~~we:

- 86 1. ~~Tested~~ing whether reproductive female size differs among the three populations,
- 87 2. ~~When sizes vary between populations, to test~~Examined how that variation is associated with
- 88 reproductive traits, especially in fecundity, egg and clutch size, egg shape, and the egg size-
- 89 ~~number~~clutch size trade-off;

3. To test whether variations exist in the examined the relationships of female traits to egg and clutch size and egg number in and among populations.

2 and 3 look essentially the same.

2 Materials and Methods

2.1 Study site

The populations studied here occur at are in three ecologically distinct locations: Bei Tun city (BT: 87°15' E, 47°26' N), Fu Yun city (FY: 89°05' E, 46°36' N), and Yi Ning city (YN: 80°47' E, 43°40' N) of the Xinjiang Uyghur Autonomous Region, China. The distance between the BT and the YN populations is about 660 km and their habitats are different, and the geographic variation in their habitat is great. The BT population occupies a typical gravel desert with little vegetation, while the YN population occupies a loam desert with abundant vegetation, especially shrubs. Geographic variation in their climates also exist. YN is hotter and wetter has a higher mean air temperature and more precipitation compared to than BT. The distance between the FY and BT are separated by populations is shorter (about 160 km) than that between and FY and YN by (about 700 km). However, habitat and precipitation in FY is similar to YN in vegetation and rainfall are similar to those in YN, while the mean air temperature of FY is similar to Bt while FY and BT have similar temperature regimes (Fig.1 and Fig.2).

2.2 Animal and egg collection

From May 2014 to May 2017, we collected specimens of *P. helioscopus* by hand from the outskirts of BT (in 2014, Liang *et al.*, 2015), FY (in 2017), and YN (in 2017) and took them. We transported the lizards to the Xinjiang Agricultural University, where the female lizards were individually palpated to assess determine their reproductive state (Li

112 *et al.*, 2006). Fifty-three gravid females (BT: 13, FY: 24, YN: 16) were housed individually in
 113 plastic cages. ~~These cages were placed~~ in a room ~~with~~ here ambient temperatures ~~were~~ never
 114 ~~higher than~~ above 28°C ~~and the room lights were programmed to create~~ with a 12-hour light
 115 /12-hour dark cycle. A 250 W light bulb was suspended at one end of each cage, 20 cm above
 116 the cage floor and lizards could freely move to warmer and cooler places within the
 117 cage. Mealworms (larvae of *Tenebrio molitor*) and water enriched with vitamins and minerals
 118 were provided *ad libitum*. Female in cages will continuously dig before they lay
 119 eggs, which allowed us to. This behaviour helped us collect eggs quickly, and prevented the
 120 and prevented eggs from absorbing water in the moist substrate. The cages were checked
 121 every 2 hours for eggs. All eggs are used in this study were collected no more than 20
 122 minutes after they had been laid.

Minimum temperature?

And, how did you randomly collect animals? Is it possible that behavior of lizards influenced your probability to get females of similar sizes/ages in all three locations?

Unknown Author
06/21/2018 14:36

What was the substrate?

Unknown Author
06/21/2018 14:37

123 2.3 Morphology and Reproductive Traits

124 We measured female snout-vent length (SVL), ~~body mass (BM, female post-oviposition~~
 125 ~~mass, 0.01 g)~~, tail base width (TBW), egg length (EL), and egg width (EW)
 126 by using digital calipers (measured to the nearest 0.01 mm). We also ~~recorded~~ noted clutch
 127 size (CS). We weighed females after oviposition, eggs ~~mass~~ (EM) and clutches ~~mass~~ (CM) by
 128 on an electronic balance (measured to the nearest 0.01 g). We ~~calculated~~ used relative clutch
 129 mass (RCM, $RCM = CM / BM$) as a proxy measure of female fecundity (Shine, 1992).
 130 The ratio of egg length to egg width (EL / EW) ~~value represents~~ indicates the general shape
 131 of the eggs (egg shape, ES), where 1 is a round egg, and larger values are increasingly
 132 elongate a larger value means the egg has an elongated shape, and a smaller value indicates
 133 a rounder shape (Ji & Wang, 2005; Kratochvíl & Frynta, 2006).

You did not measure body mass with calipers.... You should put things measured together and things weighed together, but not mix the two.

Unknown Author
06/21/2018 14:40

Why? After all, you are going to compare all the principle variables. Calculating a ratio is unnecessary as a method.

Unknown Author
06/21/2018 14:43

134 2.3 Statistical analyses

135 Data were tested for normality using the Kolmogorov-Smirnov test, and for
136 homogeneity of variance using Bartlett's test. The parametric tests will be applied when
137 normality (and homogeneity of variance) assumptions are satisfied otherwise the equivalent
138 non-parametric test will be used. For this reason, the Kruskal-Wallis test was used in
139 conjunction with the *wmc* function (<http://www.statmenthods.net/RiA/wmc.txt>), as multiple
140 comparisons were necessary when examining variations in SVL, EM, and ES among the
141 three populations. ANCOVA was used to examine variation in TBW, EL, EW, RCM, and CS
142 among the three populations by *post hoc* Tukey's tests (multiple comparisons). To test egg
143 size-number trade-off and analyze potential morphological constraint on optimal egg size, the
144 relationships of EM and EL with CS, of EM with EL, of EL and CS with SVL, and of EW
145 with TBW were examined using RMA (Reduced Major Axis regression) regression rather
146 than OLS (Ordinary least squares) regression, because RMA accounts for an error in the
147 independent variable (Dunham & Miles, 1985). ~~Data~~Variables (except CS) were log₁₀-
148 transformed to improve linearity and enable comparison with other studies (King, 2000),
149 except in CS, because it does not vary logarithmically. Historical climatic data
150 (1990-2013) of the three study areas was taken from the Chinese National Climatic Data
151 Center (<http://data.cma.cn>). Descriptive statistics were represented as follows: mean adjusted
152 (calculate by the effect function of effect package) ± SE, except in SVL, EM, and ES, which
153 are represented as the mean ± SE. Differences were considered significant when
154 $P < 0.05$.
155 All analyses were conducted using the software R v.3.4.1 (R Core Team 2017),

"Data" do not need to be tested for normality. In regressions and ANOVA, the residuals need to be tested. It is likely that you did not need to use a nonparametric test, but rather you could have log10 transformed your measurements – which is the normal practice.

Unknown Author
06/21/2018 14:45

Is this spelled correctly? Is this a working link? I could not access it. Also, you should probably use Tukey for multiple comparisons.

Unknown Author
06/21/2018 14:47

You're not "examining" variation, but rather testing how each population differs.

Unknown Author
06/21/2018 14:52

Again, you're not examining variation.

Unknown Author
06/21/2018 14:53

156 employing the packages “lmodel2” (Legendre, 2011), “effects” (Fox & Hong 2009),

157 “ggplot2” (Wickham 2015), “gplots” (Warnes *et al.*, 2011).

169

170 Figure 2 Means for monthly mean air temperature (A) and monthly mean rainfall (B) over the

171 past 24 years (1990-2013) at the three localities, where females of

172 *P. helioscopus* were collected. BT: pink; FY: green; YN: light blue.

173 3 Results

174 3.1 Maternalfemale morphological variation

175 SVL varied between populations and was longest in the similar YN and FN populations

176 (YN: 51.23 mm; FY: 50.43 mm), and shortest in the BT population

177 ($\chi^2 = 25.05$, $P < 0.0001$). ANCOVA with SVL as a covariate revealed that TBW varied
178 between populations and was smallest in the similar YN and FN populations (YN: 7.20 mm;
179 BT: 6.93 mm), and largest in the FY population ($F_{2,52} = 6.82$, $P = 0.002$) (Fig. 3).

I don't understand why you inserted tables and figures into the text.

Unknown Author
06/21/2018 15:14

I don't think you need to worry about differences in 4% between the two levels, because they do NOT indicate importance. Rather, you should talk about the r^2 values of each, because they DO indicate how much is being explained by location. I think you can just leave the alpha level at 0.05. Also, you should have lower case letters for figure 2A.

Unknown Author
06/21/2018 15:16

Unnecessary. You cannot say they are different if they are also not significantly different.

Unknown Author
06/21/2018 15:28

182 Figure 3. Comparisons between A) snout-vent length and B) tail width at base, of gravid
183 females in three populations of *Phrynocephalus helioscopus*. Points are means with 95%
184 confidence intervals. Different lowercase letters means significant at the 0.05 level; different
185 uppercase letters mean significant at the 0.01 level

186 3.2 Female Reproductive Traits

187 EM differed significantly among the three populations, with Females in the FY
188 femalespopulation laying significantly heavier eggs than both those in the BT and YN
189 populations. Eggs were similar in length in all from the three populations did not differ from
190 each other in EL. EW varied between populations and was the widest Eggs were wider
191 (rounder, EW) in the FN population and the narrowest in the YN population. CS varied
192 among the three populations, with BT females laying fewer eggssmaller clutches than the
193 FY and YN females with the samewhen controlling for SVL. There were significant
194 differences in RCM among the three populations, with tThe FY population having a a larger
195 RCM ratio than the BT population. There were significant differences in ES among the three
196 populations, with tThe BT population having a longerhad longer eggs. ES than the than FY
197 population (Table1).

But, EW and ES are two ways to measure the same thing. So, if you are going to talk about ES, you need NOT talk about EW once you mention egg length. ES is just a combination of EL and EW! You can't talk about all three as if they were independent.

Unknown Author
06/21/2018 15:34

Table 1. Descriptive statistics of female reproductive traits in the three populations of *Phrynocephalus helioscopus*.

Variable	BT (n = 35)	FY (n = 90)	YN (n = 63)	F-level and P-value
EM (g) [†]	0.51±0.02 ^B	0.61±0.02 ^A	0.55±0.01 ^B	$\chi^2 = 20.96, P < 0.0001$

[#] One-way analyses of covariance (ANCOVAs) (for CS with SVL as the covariate, for EL and EW with egg mass as the covariate, and for RCM with BM as the covariate);

* BT n=13, FY n=24, YN n=16.

3.3 Egg Size-Number clutch size Trade-offs

We found a positive relationship in all populations. In the BT and FY females population, there was a relationship between EL and EM.

I don't understand why you embedded the tables. You also supplied them as attachments, so that was fine.

Unknown Author
06/21/2018 15:36

Because you have some of these comparisons in the figures, you do NOT need to repeat them in a table.

Unknown Author
06/21/2018 15:37

r² values would be useful.

Unknown Author
06/21/2018 14:57

Why chi-squared instead of F? After all, this should be a simple ANOVA.

Unknown Author
06/21/2018 14:56

Unnecessary. You can just use 0.05 and only one kind of letter.

Unknown Author
06/21/2018 15:38

Of course, because EW was relatively constant! So, the only way egg weight could vary is by differences in length.

Unknown Author
06/21/2018 15:39

significant negative relationship between egg size decreased with and number clutch size. In the FY population, there was also a significant negative relationship between egg size and number, while in the YN females, egg size was independent of clutch size population, there was no significant relationship between egg size and number (Table 2, Fig. 4). The existence of this negative relationship between egg size and CS provides evidence of egg size-number trade-offs in both the BT and FY populations.

Population					
s	Variables	Slope (95% CI)	Intercept (95%CI)	R ²	P-value
BT	EM-CS	-0.12 (-0.16~-0.09)	0.86 (0.78~0.98)	0.36	0.001
	EL-CS	1.89 (-2.61~-1.36)	20.40 (18.89~22.50)	0.12	0.039
	EL-EM	0.46 (0.36~0.59)	1.31 (1.28~1.35)	0.45	<0.001
FY	EM-CS	-0.15 (-0.17~-0.12)	1.19 (1.09~1.30)	0.27	<0.001
	EL-CS	-1.88 (-2.24~-1.57)	22.24 (21.04~23.68)	0.3	<0.001
	EL-EM	0.52 (0.47~0.57)	1.28 (1.27~1.29)	0.78	<0.001
YN	EM-CS	0.20 (0.16~0.26)	-0.26 (-0.49~-0.08)	0.004	0.602
	EL-CS	-2.36 (-3.04~-1.83)	24.18 (22.06~26.90)	0.008	0.471
	EL-EM	0.43 (0.37~0.51)	1.28 (1.26~1.30)	0.6	<0.001

Table 2. Relationships between EL and EM and egg size-number trade-

offs

Figure 4. Regressions of EL and EM and egg size-number trade-off of

Phrynocephalus helioscopus. BT -Shaded triangles with dashed line, FY - Asterisk with solid line, YN - Unshaded triangle with dashed line.

3.4 The Relationship Between Egg Size, Number and Female Morphology

In the BT and YN populations, there were no significant relationships between maternal female morphological traits were independent of and either EL, EW, or CS. In

Discussion.

Unknown Author
06/21/2018 15:41

If these were in the figures, you do not need to repeat them here. Also, the legend is in the wrong place. And, the table need not be embedded in the text.

Unknown Author
06/21/2018 15:41

If this is the legend, it is very incomplete. I know in R you can get the graphs to "jitter" the points (in the clutch size in A) so that it is easier to see the points. Also, the FY line in A is probably not significant or is in error. Either way, in regression, if a relationship is NOT statistically significant, you should not include a line for relationship. Also, in clutch size, your axis has fractions, and you can make the axis show the clutch size itself, and not the fractions between observed clutch sizes. That is, 2 instead of 1.5, 3 instead of 2.5 and so on. Also, in Figure 5.

Unknown Author
06/21/2018 15:45

the FY population as well, there were no significant relationships between maternal morphological traits and either EL, EW, or CS. In the YN population, while CS was independent of female measurements, there were no significant relationship between maternal traits and CS. A significant but weak positive relationship existed between EL was weakly correlated with SVL and EW and TBW were correlated showed a significant positive relationship as well (Fig. 5, Table 3).

You should indicate A, B and C when you talk about relationships. However, if the variables are independent, the figures should not have regression lines.

Unknown Author
06/21/2018 15:53

Looks redundant because of the figures.

Unknown Author
06/21/2018 15:53

Table 3 Relationship between egg and clutch size and female morphological traits of the three populations

When a relationship is NOT statistically significant, r^2 is meaningless and does not need to be reported.

Unknown Author
06/21/2018 15:54

Figure 5 Regressions of egg length (A), egg width (B), and clutch size (C) and

maternal/female morphological traits from three populations of *Phrynocephalus*

helioscopus. BT -Unshaded triangles with dashed line, FY - Asterisk with solid line, YN -

Shaded triangle with dashed line.

4 DISCUSSION

Data on the reproductive ecology of *P. helioscopus* is relatively scant. Our interpopulation

study showed We found variation in maternal/female morphological traits (SVL and TBW),

reproductive traits (EM, CS, RCM, and egg size), in the relationship between reproductive

characteristics and maternal/female morphological traits, and in egg size-number trade-offs

among the populations of *P. helioscopus*.

4.1 Variation in female morphology the three populations

Morphological traits, such as body size and body shape always vary among different

populations in animals (e.g. Snakes: Zhong *et al.*, 2017; Lizards: Horváthová *et al.*, 2013;

Turtles: Werner *et al.*, 2016). Environmental factors that exert strong effects on animal life

history traits include activity season length and food availability (Yom-Tov

et al., 2006; Horváthová *et al.*, 2013). Our study revealed that the FY and YN populations have

significantly larger SVLs ($P < 0.01$). Longer activity seasons were assumed to be the cause of

variation in the body size between the *P. helioscopus* of the YN and BT populations (lizards in

the YN population have larger SVL, Liang & Shi, 2017). Temperature, fundamentally

important for lizards is a key factor in lizard activity (Grant & Dunham 1990), was

Temperature higher in YN is higher than the other two sites localities, especially in March and

Again, incomplete legend (you could include the regression lines) and if the regression lines are not statistically significant, you do not need the figure.

November (Fig. 2-A). According to observations in YN city, *P. helioscopus* activity began to be active in mid-March and hibernation began to hibernate in early November, which means that the activity period for lizards here of this population have is almost a one-month longer growing season than lizards in the other two sites populations. It is conceivable that lizards in this population have a larger body size because of the longer growing season than the two populations.

The BT and the FY populations with have similar temperatures conditions, which raises the question as to what causes their difference variation exists in the SVL of the females of these two populations. One plausible explanation is that poor food limitation availability (e.g. insect scarcity) might have resulted in the reduced growth rates in smaller-bodied females of the BT population. Rainfall is critical to habitat quality (e.g. vegetation cover and prey abundance, see Lorenzon, Clobert & Massot, 2001). The geographic variation in rainfall in our study areas is great (Fig. 2) and the sparse vegetation in BT is might be due to its drier conditions versus the more abundant vegetation in , while vegetation is abundant in the regions where the rainfall was abundant (the FY and YN sites populations, (Fig. 1, Fig. 2-B). Humidity stands out as the most important factor regarding the influencing abundance and distribution of insects (Savopoulou-soultani *et al.*, 2012; Cesne, Wilson & Soulier-Perkins, 2015) and so. Thus, drier conditions and sparse vegetation should be associated with less food dietate that food availability will be poor.

4.2 Variation in egg and clutch size, and fecundity among the three populations

Egg size varies among populations because of variation in maternal female body size and is considered to be an important female reproduction-related trait that which can affect

But, this just means it should take the other population longer to reach the same size. If you collected similar AGED individuals, this makes sense, but if you collected adults of all ages, you do not expect this result UNLESS they also die at the same age.

278 offspring size (Morrison & Hero, 2003; Olsen & Vollested, 2003; Steyermark & Spotila,
279 2001). Our data showed that egg size differed ~~significantly~~ among the three populations
280 ~~(all cases $P < 0.05$, except for EL $P > 0.05$). The, which suggests that~~ larger females of the FY
281 and YN populations are able to devote more ~~energy to their eggs~~ resources to egg production
282 ~~(egg mass as a proxy for energy)~~. In addition, egg size is also correlated with the incubation
283 period, with smaller eggs having a relatively short incubation time (Thompson & Pianka,
284 2001). ~~Perhaps -It may be possible that in the BT population~~ smaller eggs hatch sooner
285 ~~providing offspring time to forage before entering hibernation, females obtain more growth~~
286 ~~time for their hatchlings in the field before hibernation by producing smaller~~
287 ~~eggs.~~

288 ~~It is well known that~~ Larger females ~~with a larger body size can tend to~~ lay more
289 eggs, ~~which is commonly the case among in~~ reptiles (Amat, 2008; Ryan & Lindeman, 2007).
290 ~~Thus, the smaller~~ CS of the BT population is associated with their smaller ~~smaller than that of~~
291 ~~the other two populations. This might be due to the BT population's small~~
292 ~~body size, which cannot support the CS as much as the other two~~
293 ~~populations. CS is also constrained by food resources~~ can also be limited by food
294 availability, and ~~it varies among populations and species~~ (Liao, Lu & Jehle, 2014; Roitberg
295 *et al.*, 2015). Poor food availability then is likely another important factor for the smaller CS in
296 the BT population. The BT population with the smallest RCM may also be influenced by
297 habitat, specifically through variation in food availability (Shine, 2005; Pellerin
298 *et al.*, 2016).

299 4.3 Egg shape

You already said that smaller animals is probably due to limited food, now you're saying that smaller clutches due to food, but, smaller animals lay smaller clutches. You should simply say once and for all, that the BT population can have smaller females and clutches due to shorter growing seasons and limited food availability (all in one sentence). To present the two as separate arguments ignores their dependence.

CS is also related to the egg shape of the eggs; is also related to clutch size

and larger clutches tend to have more rounded eggs; females produce a larger CS when their eggs are rounded, and less when elongated (Ji *et al.*, 2002). EL did not significantly differ among the three populations (EM as the covariate), but a variation did exist in EW. The BT population's EW Eggs were narrower in BT is smaller than that of the other two populations, so the egg shape of the BT population females were more elongated than those laid by the YN and FY populations. On the other hand, ES is associated with female and clutch size related to the crowdedness of eggs in the female's uterus due to available space in the uterus (Qu *et al.*, 2011; Ji & Wang, 2005). Both the FY and YN populations lay more, and rounder eggs (Table 1). Rounder eggs might indicate that the uteri of the females of these two populations were more tightly packed when they were gravid.

4.4 Variation in egg size-number trade-offs among the three populations

The trade-off between egg size and number/clutch size is one of the central and important concepts in life-history theory (Kern *et al.*, 2015). The egg size-number trade-offs among the three populations here are quite different. A significant negative relationship between egg size and clutch size were negatively correlated number existed in the BT and FY populations (EM and EL), but not in the YN population, indicating that in the former populations the females with larger CS produce smaller eggs by reducing the length of the eggs. In the YN population there was no egg size-number trade-off ($P > 0.05$), which is further evidence that and so intraspecific variation in the relationship between egg size and clutch size/number is widespread (Liao, Lu & Jehle, 2014; Roitberg *et al.*, 2015).

4.5 Variation in the relationships between egg size, number, and maternal/female

322 **morphology among the three populations**

323 Generally speaking, offspring phenotypes are influenced by ~~maternal~~female body size
324 (e.g., SVL, Krist & Remeš, 2004). ~~According to Lovich et al. (2012), m~~Morphological traits
325 and other factors affecting egg size ~~will~~can result in the following five possible outcomes
326 (~~Lovich et al. 2012~~): 1) egg size is constrained by female morphology (-not optimized), 2) egg
327 size is unconstrained by female morphology (optimized), 3) egg size is unconstrained by
328 female morphology and optimized only in the largest females -(~~Fehrenbach et al., 2016~~), 4)
329 egg size is not constrained by the pelvic aperture width, ~~but it~~and is not optimized, ~~as it~~
330 ~~is~~but rather is constrained by some other non-morphological factor (e.g., age or clutch
331 number, ~~Clark, Ewert & Nelson, 2001; Paitz et al., 2007; Harms et al., 2005~~), 5) egg width is
332 constrained and requires osteo-kinesis for oviposition (~~Hofmeyr, Henen & Loehr, 2005;~~
333 ~~Fehrenbach et al., 2016~~).

334 Consistent with the prediction of the morphological constraint hypothesis,
335 egg size increases as the size of the female increases (outcome 1) in the YN population.

336 Although female body size in the BT population is smaller than in the FY population, in both
337 cases, their egg size was unconstrained by ~~maternal~~female body size (outcome 2 or 4 above).

338 For some species with small body sizes, egg size is constrained by female morphology
339 (Ryan & Lindeman, 2007). In small-bodied females, the body size-specific constraints on egg
340 size coupled with selection towards an optimum egg size results in a positive correlation
341 between body size and egg size. (Smith & Fretwell 1974; Congdon & Gibbons, 1987).

342 Unexpectedly, our results revealed that constraint on egg size did exist in the large-bodied
343 females of the YN population. ~~A~~ ~~P~~positive relationships between egg size and female

Bad word to use in this context. Unconstrained should mean that small females can lay large eggs or small eggs.

344 morphology size indicates that there is no optimal egg size, as in the YN population is attained
345 in the YN populations (Escalona, Adams & Valenzuela, 2018). Furthermore, our findings
346 also But, we found provide some support to suggest that their for the prediction that EW was
347 constrained by TBW (Fig. 3), since eggs must fit the female tail base width which they pass
348 through on their smallest axis (e.g. EW). In some turtle species, EW but not EL increases with
349 the size of the female (Rasmussen & Litzgus, 2010). There was a significant positive
350 correlation between EL and female SVL in the YN population, suggesting that EL is
351 dependent upon on female SVL. Egg size (EL and EW) was not dependent on female body
352 size in either the BT or FY population, but there were significant negative correlations between
353 egg size and number (Fig. 4), suggesting that the egg size was constrained by CS (non-
354 morphological factor) in both populations (Brown & Shine, 2009, outcome 4).
355 Overall, the relationship between egg size and SVL cannot be completely explained by female
356 morphological constraints on egg size, especially for EL, because EL can be constrained by
357 morphological factors, non-morphological factors (e.g. CS), or their interactions, which may
358 indicate that a weak relationship exists between female morphology and EL exists in the YN
359 population. The specific mechanisms of the non-morphological factors require further study
360 (Kern *et al.*, 2015).

Would you not have found it?

361 CONCLUSIONS

362 In summary, our study we found geographic variation in body size and reproductive
363 strategies of the lizard *Phrynocephalus helioscopus*. Lizards in populations with longer
364 growing seasons and abundant vegetation (the FY and YN populations)
365 exhibit are larger body sizes and have greater reproductive output. The 4Lizards of the BT

population are smaller (perhaps due to food limitation or season
limitation), because they have the smallest body size and inadequate food availability, their
also have smaller clutches. CS was smaller than ~~that of the lizards of~~ the FY and YN
populations. ~~Due to their larger CS, the~~ FY and YN females populations produce rounder
eggs, perhaps due to larger body size. This study found that there were morphological
constraints on egg size in the larger-bodied females of the YN population – an anomaly for the
morphological constraint hypothesis. Egg size was not constrained by female body size and
did not follow the optimal egg size hypothesis in the BT and FY populations. Egg size-number
trade-off suggests that egg size was constrained by CS in both populations.
However, whether the existence of genetic variation is related to the differences in the life
history traits of the three populations of this species has not been examined in this study and
should be researched in the future.

Ethics approval

Specimens were collected following *Guidelines for Use of Live Amphibians and Reptiles in*
Field Research (the Herpetological Animal Care and Use Committee (HACC) of the American
Society of Ichthyologists and Herpetologists, 2004). This work was performed in compliance
with the current laws on animal welfare and research in China. After the research was
completed, the lizards were released where they were captured.

ACKNOWLEDGEMENTS

We are grateful to Prof. Lovich of the United States Geological Survey, to the Southwest
Biological Science Center, and to anonymous reviewers for their excellent help in improving
this manuscript. We thank Luo D and Wang P for assistance during fieldwork, and we thank

388 An J for help with the egg collection and lizard husbandry. Mr. T. Martin provided
389 professional advice regarding spelling and phrasing.
