17 Short title: Species delimitation of Andean glassfrogs

18 Abstract

19 The glassfrog *Centrolene buckleyi* has been recognized as a species complex. Herein, using
20 coalescence-based species delimitation methods, we evaluate the specific diversity within this
21 taxon. Four coalescence approaches (GMYCs, bGMYC, PTP, and bPTP) were consistent with
22 the delimitation results, identifying four lineages within what is currently recognized as *C.*
23 *buckleyi*. We propose three new candidate species that should be tested with nuclear markers,
24 morphological and behavioural data. In the meantime, for conservation purposes, candidate
25 species should be considered evolutionary significant units, giving observed population crashes
26 in the *C. buckleyi* species complex. Finally, our results support the validity of *C. venezuelense*,
27 formerly considered as a subspecies of *C. buckleyi*.

28 Introduction

29 Species delimitation —the process by which species boundaries are determined— is a challenge
30 for biota of biodiversity hotspots (Myers et al., 2000). Achieving a taxonomic scheme that
31 reflects the evolutionary history of organisms is critical for both theoretical (characterize
32 biodiversity) and practical (designing conservation strategies) reasons (e.g. Esselstyn et al.,
33 2012). Although species delimitation ideally uses multiple lines of evidence (Padiál et al., 2010),
34 DNA sequences play an important role in species-level lineage identification (Chambers &
35 Hebert, 2016; Pentinsaari, Vos & Mutanen, 2016). Sequences have been recently, and more
36 frequently, analyzed under coalescent-based methods (e.g. Pons et al., 2006; Yang & Rannala,
37 2010; Camargo et al., 2012; Reid & Carstens, 2012; Fujisawa & Barraclough, 2013; Zhang et al.,
38 2013). The main goal of coalescent-based species delimitation is to identify evolutionarily
39 independent lineages, where each lineage represents a single species (Fujita et al., 2012; for the

40 conceptualization of the species category, in the so called Generalized Lineage Concept, see de
41 Queiroz, 1998, 1999, 2007). Coalescent-based methods, which allow testing alternative
42 hypotheses on the divergence of a lineage, are expected to reduce the subjective bias introduced
43 by researchers, avoiding using *ad hoc* thresholds (i.e., degree of morphological, ecological,
44 and/or percentage of sequence divergence) as criteria to establish species limits. As such, these
45 methods have become a common tool for delimiting species, both to propose candidate species
46 as well as to describe new species (e.g., Leaché & Fujita, 2010; Páez-Moscoso & Guayasamin,
47 2012; Crivellaro et al., 2017).

48 Proposing candidate species, which currently is mostly done on the basis of molecular evidence
49 (e.g., Correa et al., 2017; Hurtado & D'Elía, 2018; Lin, Stur & Ekrem, 2018) is relevant to
50 distinct areas of biological research. The proposition guides future taxonomic research allowing
51 to direct the costlier efforts (e.g., field collections, morphological assessment of large specimen
52 series) to specific areas of interest. In turn, these efforts result in an acceleration of the discovery
53 and validation of new species (Dellicour & Flot, 2015; Vitecek et al., 2017), which is relevant in
54 the current era of biodiversity crisis. In addition, candidate species can be considered
55 evolutionary significant units, which in turn can be subject to conservation actions (Moritz,
56 1994).

57 The taxon *Centrolene buckleyi* (Boulenger, 1882) has a large distribution inhabiting montane
58 primary and secondary forests in high tropical Andean zones (1,900–3,300 msnm), as well as
59 inter-Andean scrubland and Páramo environments of Colombia, Ecuador, and northern Peru
60 (Duellman & Wild, 1993; Guayasamin et al., 2006; Rada & Guayasamin, 2008; Guayasamin &
61 Funk, 2009) (Fig. 1). The glassfrog *C. buckleyi* has a relatively simple taxonomic history; only

62 two taxonomic forms, *venezuelense* (Rivero, 1968) and *johnelsi* (Cochran & Goin, 1970), are
63 associated to it. The later was synonymized under *C. buckleyi* by Ruiz-Carranza & Lynch
64 (1991). Meanwhile, the form *venezuelense* was considered as a subspecies of *C. buckleyi* until it
65 was elevated to species level as *C. venezuelense* by Myers & Donnelly (1997), based on the
66 argument that it is highly unlikely that the distribution of *C. buckleyi*, with its type locality in
67 Ecuador, reaches Venezuela. Señaris & Ayarzagüena (2005) agree in considering *venezuelense*
68 at the species level, given it presents morphological and acoustic differences with respect to
69 typical *buckleyi*. Cisneros-Heredia & McDiarmid (2007), based on morphological characters,
70 stated that further research is needed to evaluate the distinction of *venezuelense* from *buckleyi*.
71 Even after the removal of *venezuelense*, distinct lines of evidence suggest that as currently
72 understood, *C. buckleyi* may encompass more than one species. For instances, Colombian
73 populations are regarded as *C. aff. buckleyi* as a way to denote uncertainties in their identity
74 (Guayasamin et al., 2008). Moreover, Guayasamin et al. (2006) identified significant call
75 variation among populations of *C. buckleyi*; similarly, several studies have shown the lack of
76 monophyly for this taxon (Guayasamin et al., 2006, 2008; Guayasamin & Funk, 2009; Pyron &
77 Wiens, 2011; Castroviejo-Fisher et al., 2014; Twomey, Delia & Castroviejo-Fisher, 2014). As
78 such, in current catalogues (e.g., Guayasamin et al., 2017) *C. buckleyi* is regarded as a species
79 complex.

80 Given these antecedents, herein, using an expanded molecular dataset, and phylogenetic and
81 coalescent-based species delimitation analyses, we evaluate the species limits of populations
82 currently allocated to the taxon *C. buckleyi*. Our study identifies four distinctive lineages, three
83 of which should be considered as candidate species.

84 **Materials & Methods**

85 A total of 34 sequences of the 12S and 16S mitochondrial genes of the genus *Centrolene* were
86 analysed; of these, ten belong to the *Centrolene buckleyi* species complex. The outgroup was
87 formed with sequences of *Nymphargus*, a genus closely related to *Centrolene* (Guayasamin et al.,
88 2008; Castroviejo-Fisher et al., 2014; Twomey, Delia & Castroviejo-Fisher, 2014). As such, the
89 analysed matrix totalizes 47 sequences (see Table S1). Sequences were downloaded from
90 Genbank or gathered by us (Tables 1, S1). The matrix includes sequences of the *C. buckleyi*
91 species complex from four localities throughout its distributions in the eastern Andean foothills
92 of Ecuador (Table 1; Fig. 1). Specimen collection was done under research permit (MAE-DNB-
93 CM-2015-0017) issued by the Ministerio del Ambiente of Ecuador (MAE). Additionally,
94 morphological characters of all specimens were examined by one of the authors (JMG).

95 **DNA extraction and sequencing**

96 For newly generated sequences, genomic DNA was extracted from 96% ethanol-preserved
97 muscle tissue samples using a modified salt precipitation method based on the Puregene DNA
98 purification kit (Gentra Systems). We amplified two mitochondrial genes 12S and 16S using the
99 primers t-Phe-frog and t-Val-frog developed by Wiens et al. (2005). PCR reactions follow the
100 protocol described by Guayasamin et al. (2008). Cycle sequencing reactions were performed by
101 Macrogen Labs (Macrogen Inc., Korea). All fragments were sequenced in both forward and
102 reverse directions with amplification primers. Sequences were deposited in GenBank (Tables 1,
103 S1).

104 **Phylogenetic analyses**

105 Four matrices were created; a single matrix with 12S, a single matrix with 16S, concatenation of
106 both fragments, these three matrices included all sequences (*Centrolene* + outgroup); and one
107 matrix formed only by sequences of *Centrolene* (34 terminals concatenated with 12S-16S
108 mtDNA genes). Sequences were aligned in MAFFT v7 under an automatic strategy (Katoh &
109 Standley, 2013). The aligned matrix was imported into Aliview (Larsson, 2014), where segments
110 that presented ambiguous alignments were excluded. All positions containing only gaps were
111 deleted. The best nucleotide substitution model was selected with ModelFinder
112 (Kalyaanamoorthy et al., 2017) using the Bayesian information criterion (BIC) and was the same
113 for the first three data sets with all sequences of *Centrolene* + *Nymphargus* (TIM2 + I + G). For
114 the matrix with only sequences belonging to *Centrolene* the selected best model was TIM2 + R3.
115 This last data set was used to infer the input genealogy in species delimitation analysis. The first
116 three were used to conduct phylogenetic analyses.

117 Phylogenetic trees were obtained using Maximum Likelihood (ML) and Bayesian inference (BI).
118 ML trees were inferred in IQ-TREE (Nguyen et al., 2015); nodal support was assessed with
119 1,000 ultrafast bootstrap replicates (Minh, Nguyen & Haeseler, 2013). Bayesian inference
120 analyses were conducted with MrBayes 3.2 (Ronquist et al., 2012) using two parallel runs of four
121 Markov chains that were allowed to run for ten million generations and that were sampled every
122 1,000 generations. The first 25% of the sampled trees were discarded as a burnin, previous to
123 construct a consensus tree with the remaining sample. Phylogenetic trees were visualized using
124 FigTree 1.4.3 (<http://tree.bio.ed.ac.uk/software/figtree/>). Clades with ML values (BV) equal or
125 above 75% and posterior probabilities values (PP) equal or greater than 0.95 were considered as
126 strongly supported. MEGA 7.0 (Kumar, Stecher & Tamura, 2016) was used to estimate

127 evolutionary divergences (genetic distances) between sequences (p-distance) of the 16S gene
128 with a bootstrap procedure of 1,000 replicates.

129 **Methods for delimiting species**

130 We used two coalescence based methods, and their Bayesian implementation, to delimit species
131 on the basis of variation of 12S and 16S sequences.

132 *Generalized Mixed Yule Coalescent (GMYC) and Bayesian General Mixed Yule-Coalescent*
133 *(bGMYC)*. -- The GMYC method uses maximum likelihood statistics and takes an estimated
134 ultrametric and bifurcating genealogy from a single-locus as input (Pons et al., 2006; Fujisawa &
135 Barraclough, 2013). The ultrametric tree was obtained with BEAST 2 (Bouckaert et al., 2014)
136 under a relaxed clock model and a birth-death model of speciation, we conducted two
137 independent analyses to check for consistency in the results. Each analysis was run for 20 million
138 generations logging every 1,000 generations. BEAST log files were checked for convergence
139 and for ESS values above 200 using Tracer v1.6 (Rambaut, Suchard & Drummond, 2014).
140 Maximum clade credibility tree was estimated with TreeAnnotator v2 (distributed as part of
141 BEAST) with the sampled trees after discarding the first 25% as burn-in. Outgroups were
142 removed with *drop.tip.simap* function of R v. 3.3.2 (R Core Team, 2016) package phytools
143 (Revell, 2012). The GMYC method attempts to model the transition point between cladogenesis
144 (Yule process) and the population level process of allelic coalescence, using the assumption that
145 cladogenesis will occur at a much lower rate than coalescence (Carstens et al., 2013; Tang et al.,
146 2014). GMYC was fitted to the ultrametric gene tree to delimit the species boundaries using
147 single (GMYCs, Pons et al., 2006) and multiple threshold models (GMYCm, Monaghan et al.,
148 2009). We compared the likelihood of single and multiple transition model with likelihood of

149 null model via a likelihood ratio test. These analyses were performed with the package Splits
150 (Ezard, Fujisawa & Barraclough, 2009) in R, after removing zero-length branches and making
151 the tree fully dichotomous. We also performed a Bayesian General Mixed Yule-Coalescent
152 (bGMYC) analysis (Reid & Carstens, 2012), which takes into account the uncertainties in the
153 estimation of the genealogy. The analysis was done with the R package bGMYC (Reid &
154 Carstens, 2012) in R, which calculates the posterior marginal probabilities of species boundaries.
155 This was performed with a post-burn-in sample of 100 trees sampled from the posterior
156 distribution of trees. For the bGMYC analysis, the priors of parameters t_1 and t_2 were set at 4
157 and 100, respectively. The bGMYC analysis was performed with 50,000 generations, with a
158 burnin of 10%, and a thinning interval of 1,000 samples.

159 *Poisson Tree Processes (PTP) and Bayesian Poisson Tree Processes (bPTP) methods.* --This
160 method models speciation and coalescence events in terms of numbers of substitutions (Zhang et
161 al., 2013). PTP provides hypothesis of species delimitation based on a gene tree (not necessarily
162 ultrametric), using heuristic algorithms to identify the most likely classification of branches in
163 processes at the level of populations and species (Tang et al., 2014). We also used bPTP, which
164 is the Bayesian implementation and updated version of the PTP method. Moreover, the result of
165 the search for the maximum probability in PTP is part of the results of bPTP. This
166 implementation produces Bayesian posterior probability values (PPV) of delimited species using
167 as input the phylogenetic tree (the same as in PTP). A higher Bayesian value ($PPV > 0.90$) at one
168 node indicates that all descendants of that node are more likely to belong to the same species
169 (Zhang et al., 2013). The PTP and bPTP analyses were performed on the web server
170 <http://species.h-its.org/ptp/>.

171 To discern among incongruent results of the species delimitation analyses, we followed the
172 reasoning of Carstens et al. (2013), relying on those delimitations schemes that are recovered in
173 the majority of the analyses.

174 **Results**

175 **Phylogenetic relationships**

176 The alignment of 47 nucleotide sequences, including the outgroups, resulted in a total of 1,641
177 positions in the final dataset. All new sequences were deposited in GenBank. The methods of
178 phylogenetic reconstruction (ML and BI) inferred identical evolutionary relationships, in
179 particular regarding the lineages of the *Centrolene buckleyi* species complex (Fig. 2).

180 The *Centrolene buckleyi* species complex is not recovered monophyletic; sequences recovered
181 from specimens of *C. buckleyi* form four main lineages, namely *C. buckleyi* sensu stricto, *C.*
182 *buckleyi* [Ca1], *C. buckleyi* [Ca2] and *C. aff. buckleyi* [Ca3] (Fig. 2). Specimens of the first
183 lineage come from the proximities of the type locality of *Centrolene buckleyi* (Intag, Imbabura
184 province, Ecuador), as such, hereafter we refer to the first lineage as *C. buckleyi* sensu stricto.

185 This form is sister to *C. ballux* in a strongly supported clade (BV=99%, PP=1); *C. buckleyi* [Ca1]
186 is sister to *C. sabini* (BV=84%, PP=0.98), while *C. buckleyi* [Ca2] is sister to a clade formed by
187 *C. venezuelense* and *C. aff. buckleyi* [Ca3] from Colombia in a highly supported clade
188 (BV=96%, PP=1) (Fig. 2).

189 **Molecular species delimitation**

190 The results obtained with the GMYCs approach, delimited 26 putative species of the matrix of
191 34 sequences of *Centrolene*; recognizing *C. buckleyi* sensu stricto, *C. venezuelense*, *C. aff.*
192 *buckleyi* [Ca3], *C. buckleyi* [Ca1] and *C. buckleyi* [Ca2] as different species (Fig. 3, see also Fig.
193 S1). The two specimens of *C. buckleyi* sensu stricto (KU17803, Cuicocha Lake, Imbabura
194 province, and MZUTI763, Oyacachi-El Chaco road, Napo province; distance between locations:
195 about 60 km) were clustered in a single lineage. Similarly, the two specimens of *C. buckleyi*
196 [Ca1] (MRy547 and MRy548, Shucos, Zamora Chinchipe province) and the three individuals of
197 *C. buckleyi* [Ca2] (MZUTI83 – MZUTI85, Yanayacu, Napo province) were clustered in a single
198 lineage, respectively. Furthermore, the two specimens of *C. venezuelense* were grouped in a
199 single lineage as well as *C. aff. buckleyi* [Ca3] was recovered as a different candidate species.
200 Meanwhile the GMYCm approach found 21 species, GMYCm was the only one of the species
201 delimitation methods that portrayed different delimitation results, greatly departing of the results
202 of the other analyses (Fig. S2). For instance, GMYCm separated the three specimens of *C.*
203 *buckleyi* [Ca2] into two different species, at the time that recovered *C. buckleyi* sensu stricto and
204 *C. ballux* as a single species; the same happened with *C. venezuelense* and *C. aff buckleyi* [Ca3]
205 that were recovered as a single entity. However, GMYCm kept *C. buckleyi* [Ca1] and *C. sabini*
206 as separate species. For both methods (GMYCs and GMYCm), the result of Likelihood ratio test
207 was not significant ($LR_{\text{testSINGLE}} = 0.063$, $LR_{\text{testMULTIPLE}} = 0.058$) and the likelihood value of
208 the GMYC model was always higher at both methods, single and multiple ($ML_{\text{SINGLE}} = 202.026$,
209 $ML_{\text{MULTIPLE}} = 202.117$) than the value of the likelihood of null model ($L = 199.268$). The
210 Bayesian implementation of the method (bGMYC) also delimited 26 putative species, the same
211 that were recovered with GMYCs (Fig. 3, see also the Klee diagram in Fig. S3).

212 The ML implementation of PTP and the Bayesian implementation of the method (bPTP),
213 considered the topology recovered with MrBayes as a guide tree. These methods delimited 26
214 putative species with good support, recovering the same delimitation results obtained with
215 GMYC and bGMYC (Figs. 3 and S4). Further details of the results of the analysis of species
216 delimitation are in Supplementary Information.

217 Average genetic distances of the 16S matrix, within and between candidate species pairs of the
218 *C. buckleyi* species complex are presented in Table S2. The maximum values between candidate
219 species were observed for the comparison between *C. buckleyi* [Ca1] with *C. buckleyi* sensu
220 stricto and *C. buckleyi* [Ca2] (1.6% and 1.8% respectively); while the lower values correspond to
221 the comparisons between *C. venezuelense* with *C. buckleyi* [Ca2] and *C. aff. buckleyi* [Ca3]
222 (0.7% and 0.4% respectively). It is also worth highlighting the low values recovered between *C.*
223 *buckleyi* sensu stricto with its sister taxa *C. ballux* (0.6%) and *C. buckleyi* [Ca1] with its sister
224 taxa *C. sabini* (0.4%).

225 Discussion

226 *Centrolene buckleyi* has been suggested to represent a species complex, requiring therefore, a
227 taxonomic revision (Guayasamin et al., 2006; Cisneros-Heredia & McDiarmid, 2007; Hutter,
228 Guayasamin & Wiens, 2013; Castroviejo-Fisher et al., 2014), which in turn would have direct
229 consequence on conservation status and strategies (the *C. buckleyi* species complex is currently
230 listed as Vulnerable by IUCN; Guayasamin, 2010).

231 In this study, we find four distinct lineages within the *buckleyi* species complex and corroborate
232 the distinction of *C. venezuelense* (but see the results of the GMYCm analysis, Fig. 3). Within

233 the current taxonomic definition of *C. buckleyi*, we propose three candidate species (namely *C.*
234 *buckleyi* [Ca1], *C. buckleyi* [Ca2] and *C. aff. buckleyi* [Ca3]) in addition to the typical form. This
235 scenario is supported by phylogenetic (ML, BI) and coalescence-based species delimitation
236 analyses (GMYC, PTP). The ML and BI analyses resulted in a tree with topology similar to
237 those of previous studies targeting glassfrogs (e.g. Hutter, Guayasamin & Wiens, 2013;
238 Castroviejo-Fisher et al., 2014; Delia, Bravo-Valencia & Warkentin, 2017), but with an
239 increased sampling within the *C. buckleyi* species complex. In all phylogenetic analyses
240 performed in this study, *C. buckleyi* is not recovered monophyletic; specimens allocated to this
241 taxon fall into four main lineages, *C. buckleyi* sensu stricto, *C. buckleyi* [Ca1], *C. buckleyi* [Ca2]
242 and *C. aff. buckleyi* [Ca3], which are not closely related (except for *C. buckleyi* [Ca2] and *C. aff.*
243 *buckleyi* [Ca3], which are recovered in the same clade with *C. venezuelense* in ML and BI
244 analysis). These distinct lineages, instead, are recovered as sister to distinct glassfrog species (*C.*
245 *buckleyi* sensu stricto - *C. ballux*, *C. buckleyi* [Ca1] - *C. sabini*, and *C. aff. buckleyi* [Ca3] - *C.*
246 *venezuelense*, respectively). Therefore, the topologies obtained here suggests that there are at
247 least four species in the *C. buckleyi* species complex. We acknowledge, however, that the
248 observed lack of monophyly of the *C. buckleyi* species complex at the mitochondrial genome
249 may be a case of differences between gene and species trees, which may be caused by distinct
250 biological processes, such as mitochondrial DNA introgression. This process has been suggested
251 for cases of other amphibians such as the Nearctic treefrogs of the genus *Dryophytes* (Bryson et
252 al., 2010, 2014) and the toads of the genus *Rhinella* (Sequeira et al., 2011). However, without
253 nuclear DNA data we cannot test if the mitochondrial-based tree inferred for the *C. buckleyi*
254 species complex departs from the species tree; as such, we have not reasons to reject it and
255 assume that represents the true evolutionary history of the group.

256 Coalescent-based species delimitation methods provide hypotheses for the delimitation of
257 species based on gene trees inferred from DNA sequences (Fujita et al. 2012). Previous studies
258 have reported the congruence in the results of methods such as GMYC and PTP when defining
259 putative species (Lang, Bocksberger & Stech, 2015; Thormann et al., 2016; Conte-Grand et al.,
260 2017). Although GMYC and PTP differ in assumptions (e.g., GMYC uses an ultrametric tree and
261 in PTP it is not required), we obtained similar results with both methods. In fact, most of the
262 used species delimitation methods agree in considering *Centrolene buckleyi* as a species complex
263 composed of at least four independently evolving lineages. GMYC provided consistent diversity
264 estimates for BEAST trees (Talavera, Dincă & Vila, 2013; Tang et al., 2014). This method gives
265 better results when the guide tree is well supported; otherwise it may tend to overestimate (or
266 underestimate) the number of candidate species (Fujisawa & Barraclough, 2013; Leavitt, Moreau
267 & Lumbsch, 2015). In addition, GMYC is generally stable in the presence of a certain number of
268 singletons, as is our case (Monaghan et al., 2009; Pons et al., 2006). The results of GMYC with
269 multiple threshold (which searches for more than one probable scenario of speciation) gave a
270 smaller number of candidate species than the other methods; when the GMYC method was used
271 with a single threshold (GMYCs), results were in line with those of bGMYC, PTP and bPTP. It
272 should be noted that bGMYC has been successfully applied in other studies that examined
273 species delimitation in amphibians (Lawson et al., 2015; De Andrade et al., 2016), however, this
274 method could also fail due to errors associated with unilocus data (e.g., selection, error in gene
275 tree estimation, incomplete lineage sorting; Satler, Carstens & Hedin, 2013). Both PTP
276 approaches, ML-PTP and bPTP (adding Bayesian PPV) gave exactly the same result; these
277 methods simultaneously inferring speciation events based on change in the number of
278 substitutions in the internal nodes (Zhang et al., 2013). When visualizing the likelihood plot of

279 each delimitation method, we observed that the MCMC chains converged, which suggests that
280 the PTP results are reliable (Fig. S5). In bPTP, high values of Bayesian support were obtained,
281 which were calculated as the number of occurrences of all the descendants under a particular
282 node, and are the posterior probabilities that these taxa form a single species under the PTP
283 model (Zhang et al., 2013). The results obtained with the methods GMYC and PTP are
284 consistent; however, this scheme should be viewed with caution, mainly due to intrinsic factors
285 of the mitochondrial genes (e.g. smaller genome size, high mutation rates), to the sampling
286 coverage of the taxa, and to the time of divergence between taxa (Talavera, Dincă & Vila, 2013;
287 Luo et al., 2018), which could regard intraspecific structure as distinct species (Satler, Carstens
288 & Hedin, 2013; Sukumaran & Knowles, 2017).

289 One of the main limitations of our study is that our genetic sampling covers only a fraction of the
290 historical distribution range of the *Centrolene buckleyi* species complex. The limited sampling is
291 consequence of population crashes observed across distributional range of this species complex.
292 For instance, Bustamante et al. (2005) mentioned that *C. buckleyi* has disappeared or is rarely
293 found at localities where it used to be abundant. Similarly, Guayasamin et al. (2006) carried out
294 intensively fieldwork in Yanayacu during three years and only found three individuals of what
295 we recognize as *C. buckleyi* [Ca2]. Finally, historically *C. buckleyi* has been reported in several
296 localities and different vegetation formations in 10 different provinces of Ecuador; however,
297 only four populations had been recorded between the years 1997 and 2007 (Cisneros-Heredia &
298 McDiarmid, 2007). Two of these populations correspond to the candidate species that we
299 propose herein (*C. buckleyi* [Ca1] and *C. buckleyi* [Ca2]). Thus, in the scenario of widespread
300 population declines, our findings of distinct independently evolving lineages within the *C.*

301 *buckleyi* species complex make a strong case for increasing efforts aimed to avoid their
302 disappearance.

303 Here we show the existence of candidate species in the *Centrolene buckleyi* species complex.

304 Although the morphology of all candidate species matches the description of *C. buckleyi*, calls

305 from the so far studied candidate species are different (see Guayasamin et al., 2006). This

306 observation matches the fact that calls of populations from the Cordillera Occidental of

307 Colombia, approximately 180 kilometers west of the locality of *C. aff. buckleyi* [Ca3] (Bolívar,

308 Grant & Osorio, 1999) and those of *C. buckleyi* [Ca2] (Yanayacu Biological Station (YBS) in

309 northeast of Ecuador) are different. Guayasamin et al. (2006) found that the call of *C. buckleyi*

310 [Ca2] in YBS consisted of 1-5 notes and fundamental frequency = 4,139 Hz which is

311 considerably distinct from that of specimens from Colombia that consists of a single note and

312 fundamental frequency = 5,200 Hz.

313 Overall genetic comparisons between species pairs are not related with geographic distances. For

314 example, despite the large geographic distance separating the analyzed populations of *C.*

315 *buckleyi* [Ca2] with those of *C. venezuelense* and *C. aff. buckleyi* [Ca3] (approximately 1300 km

316 and 700 km, respectively; see Table 1), the genetic differences for the 16S matrix are low (0.7%

317 and 0.9%). The same pattern is seen for *C. sabini* and *C. buckleyi* [Ca1] that have a very low

318 genetic distance (0.4%) and approximately 1300 km of geographic distance. On the other hand,

319 for the pair *C. buckleyi* sensu stricto and *C. buckleyi* [Ca2], whose populations in the cloud

320 forests of the Ecuadorian Napo province, are separated by only 45 km, present a large genetic

321 distance than the previous comparisons (1.4%). Moreover, in general, sister species of

322 *Centrolene* show low levels of genetic divergence. For example, between *C. altitudinale* and *C.*

323 *notostictum* there is a divergence of 0.7%, a similar low value (0.6%) is found between *C.*
324 *huilense* and *C. muelleri* (CORBIDI 14667) (see Table S2). It has been suggested that most
325 speciation events of *Centrolene* occurred during the last five million years, mostly mediated by
326 the Andes uplift (Lynch & Duellman, 1997; Hutter, Guayasamin & Wiens, 2013; Castroviejo-
327 Fisher et al., 2014). This rapid and recent speciation could explain both the low genetic
328 differences found among species, as well as the little morphological divergence observed in the
329 *C. buckleyi* species complex. A similar pattern has been observed in the plump toad
330 *Osornophryne bufoniformis*, another high-Andean anuran species distributed in the northern
331 Andes of Ecuador and Colombia (Páez-Moscoso & Guayasamin, 2012).

332 Some of the candidate species that are suggested in our study (Fig. 3) seem to be delimited by
333 well-characterized biogeographic barriers. For example, *C. sabini* (Kosñipata valley, Cusco
334 Department, Peru) and *C. buckleyi* [Ca1] (Zamora Chinchipe, southern Ecuador) are separated
335 by the Huancabamba Depression, an important geographic barrier delimiting distinct
336 communities of high-Andean amphibians (see Catenazzi et al., 2012; Hutter, Guayasamin &
337 Wiens, 2013; Castroviejo-Fisher et al., 2014; Hutter, Lambert & Wiens, 2017). Another well-
338 supported example of sister species of Andean frogs separated by geographical barriers are
339 rainfrogs of genus *Pristimantis*, such as *P. cedros* and *P. pahuma* separated by the Guayllabamba
340 River in northern Ecuador (Hutter & Guayasamin, 2015).

341 The inferences drawn up in this study should be taken as conservative when evaluating species
342 boundaries of the *Centrolene buckleyi* species complex, mainly because our population sampling
343 is relatively low and to the use of single-locus based methods. The hypothesis posed here should
344 be used as a preliminary perspective of species boundaries and not as the only evidence

345 necessary to circumscribe species (Leavitt, Moreau & Lumbsch, 2015). However, the lack of
346 monophyly of *C. buckleyi* as currently delimited, constitutes strong evidence of the existence of
347 hidden specific diversity. Having said that, before formalizing any taxonomic change (i.e.,
348 describing and naming any new species), further studies integrating morphological variation as
349 well more geographical samples, additional behavioural (calls) and genetic data (nuclear
350 markers), are needed to test our taxonomic hypothesis (Olave, Solà & Knowles, 2014;
351 Sukumaran & Knowles, 2017).

352 **Conclusions**

353 We highlight that our study is in line with several others showing a pattern of high levels of
354 cryptic diversity in amphibians of tropical South America, including glassfrogs (e.g. Páez-Vacas,
355 Coloma & Santos, 2010; Funk, Caminer & Ron, 2012; Hutter & Guayasamin, 2012, 2015;
356 Gehara et al., 2014; Twomey, Delia & Castroviejo-Fisher, 2014; Ortega-Andrade et al., 2015;
357 Tarvin et al., 2017). As such, we note, that in this era of biodiversity crisis, it is urgent to
358 increase the rate in which the biodiversity is characterized. Therefore, intense fieldwork and
359 museum-based research are much needed. This message should be made clear to scientists, as
360 well as to governmental authorities that regulate research activities.

361 **Acknowledgements**

362 We thank César Marín, Natalí Hurtado, Ewan Twomey, two anonymous reviewers, and the
363 editors for their valuable comments on an earlier version of this contribution. LA wants to thank
364 Mayra García, Dharma Amador, and Gael Amador for their constant support. Thanks to José
365 Núñez for his advice on analysis of coalescence based species delimitation.

629 **Table legends**

630 **Table 1.** Names, museum codes, localities and GenBank accession numbers of sequences of
631 specimens of *Centrolene buckleyi* species complex analysed in this study. Sequences gathered
632 here are written in bold.

633 **Figure legends**

634 **Figure 1.** Distribution of *Centrolene buckleyi* species complex. *Centrolene buckleyi* sensu stricto
635 (KU 178031 Imbabura province, Ecuador and MZUTI 763 Napo province, Ecuador, blue
636 circles); *C. buckleyi* [Ca1] Shucos, Zamora province, Ecuador (orange circle); *C. buckleyi* [Ca2]
637 Yanayacu, Napo province, Ecuador (green circle); *C. aff. buckleyi* [Ca3] MAR 371 Chingaza
638 National Park, Cundinamarca, Colombia (purple circle); *C. venezuelense* EBRG 5244 Páramo de
639 Maraisa, Mérida, Venezuela (red circle). *C. ballux* in Ecuador (black triangle) and *C. sabini* in
640 Peru (black star).

641 **Figure 2.** ML tree depicting phylogenetic relationships of species of the genus *Centrolene* based
642 on the concatenated dataset of 12S + 16S sequences. Gray nodes represent Bayesian posterior
643 probabilities equal or greater than 0.95 and ML bootstrap values equal or greater than 75%.
644 Species names with different colours represent lineages within the *Centrolene buckleyi* species
645 complex.

646 **Figure 3.** Maximum clade credibility of DNA sequences of glassfrogs of the genus *Centrolene*
647 based on mitochondrial DNA (12S and 16S) showing a comparison of the results of distinct
648 species delimitation methods (see text for details). Each coloured bar represents a candidate
649 species delimited by each method employed. The gene tree is from a BEAST 2 analysis under a

650 relaxed clock with a Birth-Death model tree prior. Node height was determined using mean
651 height across the posterior distribution. Asterisks above branches represent Bayesian posterior
652 probabilities equal or greater than 0.95. The outgroup (*Nymphargus*) was removed prior to the
653 analyses. Figure inserted in the upper left end corresponds to log lineages through time plot,
654 which shows an increase in the rates of branching to the present, probably corresponds to the
655 change from interspecific to intraspecific branching events.
