Background. Dyslipidemia contributes to the risk of many diseases, including stroke, cardiovascular disease and metabolic-related diseases. Previous studies have indicated that single nucleotide polymorphisms (SNPs) are associated with different levels of serum lipid. Therefore, this study explored the relationship between the *APOA1/C3/A4/A5-ZPR1-BUD13* gene cluster gene polymorphisms and dyslipidemia in the total sample population and stratified by genders in a northeast Chinese population.

Methods. A total of 3850 participants from Jilin Province, China, were enrolled in our study, and their serum lipid levels were measured. Six functional SNPs (*APOA1* rs5072, *APOC3* rs5128, *APOA4* rs5104, *APOA5* rs651821, *ZPR1* rs2075294 and *BUD13* rs10488698) were genotyped using polymerase chain reaction and MALDI-TOF-MS. Logistic regression analysis was performed to explore the relationship of *APOA1/C3/A4/A5-ZPR1-BUD13* gene cluster gene polymorphisms with dyslipidemia. Linkage disequilibrium and haplotype analyses were performed with SNPStats program and Haploview software.

Results. All SNPs conformed to Hardy-Weinberg Equilibrium. Logistic regression analysis revealed that rs5072, rs5128 and rs651821 were associated with hypertriglyceridemia, rs5104 and rs651821 were associated with low-HDL cholesterolemia in overall group. rs651821 was associated with hypertriglyceridemia and low-HDL cholesterolemia in both the male and female group. However, among females, rs5072 was observed to be associated with hypertriglyceridemia. Haplotype analysis showed that haplotypes TGCCGC and CAGCGC were associated with dyslipidemia in the overall, male and female groups.

Conclusion. SNPs in the *APOA1/C3/A4/A5-ZPR1-BUD13* gene cluster were associated with dyslipidemia. Furthermore, the association of *APOA1* rs5072 in this gene cluster with dyslipidemia differed between genders; thus, additional studies are needed to confirm this conclusion, and the mechanisms underlying these results warrant further exploration.

31   **Abstract**

32   **Background.** Dyslipidemia contributes to the risk of many diseases, including stroke,

33   cardiovascular disease and metabolic-related diseases. Previous studies have indicated that single

34   nucleotide polymorphisms (SNPs) are associated with different levels of serum lipid. Therefore,

35   this study explored the relationship between the *APOA1/C3/A4/A5-ZPR1-BUD13* gene cluster

36   gene polymorphisms and dyslipidemia in the total sample population and stratified by genders in

37   a northeast Chinese population.

38   **Methods.** A total of 3850 participants from Jilin Province, China, were enrolled in our study, and

39   their serum lipid levels were measured. Six functional SNPs (*APOA1* rs5072, *APOC3* rs5128,

40   *APOA4* rs5104, *APOA5* rs651821, *ZPR1* rs2075294 and *BUD13* rs10488698) were genotyped

41   using polymerase chain reaction and MALDI-TOF-MS. Logistic regression analysis was

42   performed to explore the relationship of *APOA1/C3/A4/A5-ZPR1-BUD13* gene cluster gene

43   polymorphisms with dyslipidemia. Linkage disequilibrium and haplotype analyses were

44   performed with SNPStats program and Haploview software.

45   **Results.** All SNPs conformed to Hardy-Weinberg Equilibrium. Logistic regression analysis

46   revealed that rs5072, rs5128 and rs651821 were associated with hypertriglyceridemia, rs5104 and

47   rs651821 were associated with low-HDL cholesterolemia in overall group. rs651821 was

48   associated with hypertriglyceridemia and low-HDL cholesterolemia in both the male and female

49   group. However, among females, rs5072 was observed to be associated with hypertriglyceridemia.

50   Haplotype analysis showed that haplotypes TGCCGC and CAGCGC were associated with

51   dyslipidemia in the overall, male and female groups.

52   **Conclusion.** SNPs in the *APOA1/C3/A4/A5-ZPR1-BUD13* gene cluster were associated with

53   dyslipidemia. Furthermore, the association of *APOA1* rs5072 in this gene cluster with dyslipidemia

54   differed between genders; thus, additional studies are needed to confirm this conclusion, and the

55 mechanisms underlying these results warrant further exploration.

56 **Keywords:** *APOA1/C3/A4/A5-ZPR1-BUD13* gene cluster, single nucleotide polymorphism

57 (SNP), dyslipidemia

58 **Background**

59 Dyslipidemia, which is characterized by abnormally increased total cholesterol (TC),

60 triglycerides (TG), low-density lipoprotein cholesterol (LDL-C) and decreased high-density

61 lipoprotein cholesterol (HDL-C) levels, is a well-established risk factor for cardiovascular diseases

62 (CVD)(El Hajj et al. 2016; Parhofer 2015; Rai et al. 2016) and contributes to metabolic syndrome

63 (MetS), stroke and other metabolism-related diseases(Albai et al. 2017; Amalakanti et al. 2016;

64 Wang et al. 2017; Wu et al. 2016). A nationally representative survey in China indicated that the

65 prevalence of high TC, high LDL-C, low HDL-C and high TG in Chinese adults over the age of

66 18 was 6.9%, 8.1%, 20.4% and 13.8%, respectively(Zhang et al. 2018). Previous studies involving

67 epidemiological surveys found that diet, exercise and other environmental risk factors may be

68 associated with abnormal serum lipid levels(Tan et al. 2016). However, genetic factors could also

69 partially explain the development of dyslipidemia(Dron & Hegele 2016; Dron & Hegele 2018;

70 Weiss et al. 2006).

71 The *APOA1/C3/A4/A5-ZPR1-BUD13* (APO, apolipoprotein; ZPR1, zinc finger; BUD13,

72 BUD13 homolog) gene cluster is located on chromosome 11q23.3, and the apolipoprotein gene

73 cluster at this location has been revealed to be more often associated with lipid traits via genome-

74 wide association study (GWAS)(Braun et al. 2012; Willer et al. 2013). APOA1 synthesis and

75 lipolysis promote HDL-mediated reverse cholesterol transport by generating cholesterol

76 acceptors(Reichl & Miller 1989); therefore, APOA1 plays an important part in lipid metabolism,

77 especially that of HDL cholesterol. The major function of APOC3 in lipid metabolism is to inhibit

78 lipoprotein lipase (LPL); thus, the concentrations of plasma APOC3 are positively associated with

79 TG concentrations(Ooi et al. 2008). APOA4 modulates the activation of LPL by APOC2(Goldberg

80 et al. 1990) and participates in reverse cholesterol transport(Stein et al. 1986). The transcription of

81 APOA4 is regulated synchronously with that of APOA1, supporting the relationship between these

82   apolipoproteins(Malmendier et al. 1991), and APOA4 is associated with TG and HDL levels.

83   APOA5 is a component of HDL and regulates TG levels via hydrolysis of TG-rich lipoproteins

84   and endocytosis of lipoprotein remnants(Forte et al. 2009). *BUD13* encodes the BUD13 homolog

85   protein, which is one of the subunits of the splicing factor that affects nuclear pre-mRNA

86   retention(Brooks et al. 2009). *ZPR1* encodes a regulatory protein involved in cell proliferation and

87   signal transduction(Galcheva-Gargova et al. 1996). In summary, based on the above mechanisms,

88   this gene cluster can influence lipid levels, therapy contributing to the risk of dyslipidemia.

89   Relevant studies have been conducted to explore the relationship between serum lipid levels

90   and genetic loci in this gene cluster among different ethnic groups(Aung et al. 2014a; Aung et al.

91   2014b; Hsueh et al. 2017; Suarez-Sanchez et al. 2017; Yin et al. 2011). However, to the best of

92   our knowledge, there have been few studies conducted in northeast Chinese populations that

93   explore the relationship between the *APOA1/C3/A4/A5-ZPR1-BUD13* gene cluster and

94   dyslipidemia. Functional SNP may influence gene and protein expression. This study assessed the

95   association of tag and well-studied SNPs (*APOA1* rs5072, *APOC3* rs5128, *APOA4* rs5104, *APOA5*

96   rs651821, *ZPR1* rs2075294 and *BUD13* rs10488698) selected from the Han Chinese data in

97   Haploview (http://hapmap.ncbi.nlm.nih.gov/) and based on previous studies(Wu et al. 2015; Wu

98   et al. 2016) with dyslipidemia in the overall sample and stratified by genders in a large sample

99   from a Han Chinese population.

100   **Materials and Methods**

101   **Study population**

102   The Project of Present Situation and Change Forecast of Disease Spectrum in Jilin Province,

103   China, was conducted from June 2012 to August 2012 among individuals aged 18 to 79 years in

104   all nine areas of Jilin Province. This project was a cross-sectional and representative survey of Jilin

105   Province, China, which aimed to evaluate the prevalence and risk factors associated with chronic

106   diseases(Wang et al. 2015). The genetic associations results for dyslipidemia-related diseases have

107   been reported in previous studies(Su et al. 2016; You et al. 2018; You et al. 2017). The whole

108   sample size of the survey was 21435, and the participants in our present study were randomly

109 chosen from the whole sample. They were unrelated members of the Han population, and

110 individuals with a family history of dyslipidemia and other metabolic diseases or without complete

111 serum lipid data were excluded; the participants were excluded if they were being treated with any

112 drugs that may affect lipid parameters. In total, 3850 participants (1927 males and 1923 females)

113 were enrolled in the association study between the *APOA1/C3/A4/A5-ZPR1-BUD13* gene cluster

114 and dyslipidemia.

115   Dyslipidemia was assessed according to the Guidelines on Prevention and Treatment of

116 Dyslipidemia in Chinese Adults(Prevention & Adults 2007): hypertriglyceridemia, TG $\geq$ 2.26

117 mmol/L; hypercholesterolemia, TC $\geq$ 6.22 mmol/L; hyper-LDL cholesterolemia, LDL-C $\geq$ 4.14

118 mmol/L; low-HDL cholesterolemia, HDL-C < 1.04 mmol/L.

119   For laboratory evaluation, including the assessment of total TC, TG, HDL-C and LDL-C

120 levels, 5-mL blood samples were collected from each individual. The blood samples were

121 transported under refrigeration and then stored at -20°C. Our study was approved by the ethics

122 committee of the Jilin University School of Public Health (2012-R-011), and all subjects in this

123 study signed a written informed consent form.

124 **SNP selection**

125   Tag   SNPs   were   selected   from   the   Han   Chinese   data   in   Haploview

126 (http://hapmap.ncbi.nlm.nih.gov/). Other functional or well-studied SNPs were simultaneously

127 selected based on previous studies(Wu et al. 2015; Wu et al. 2016) that have documented

128 associations between SNPs in the *APOA1/C3/A4/A5-ZPR1-BUD13* gene cluster and lipid levels.

129 The minor allele frequency (MAF) criterion for these SNPs was a MAF greater than 0.05 in the

130 Chinese Han population. Finally, 6 SNPs were included in this study: *APOA1* rs5072, *APOC3*

131 rs5128, *APOA4* rs5104, *APOA5* rs651821, *ZPR1* rs2075294 and *BUD13* rs10488698.

132 **DNA extraction and genotyping**

133   Genomic DNA was extracted from peripheral blood lymphocytes following the protocols

134 provided with a commercial DNA extraction kit (JiuNa biology, Hangzhou, China). Genotyping

135 of each SNP was performed via MALDI-TOF-MS (Sequenom, San, Diego, CA, USA) with a

136 MassARRAY system. Completed genotyping reactions were dispensed onto a 384-well

137 SpectroCHIP using a MassARRAY nanodispenser (Sequenom).

138 The detection rates for the 6 SNPs were 99.7%, 99.6%, 95.8%, 99.6%, 99.8%, and 99.8% (for

139 *APOA1* rs5072, *APOC3* rs5128, *APOA4* rs5104, *APOA5* rs651821, *ZPR1* rs2075294 and *BUD13*

140 rs10488698, respectively).

Statistical analysis

142 Continuous variables with a normal distribution were summarized as the mean ± standard

143 deviation and compared by Student's t-test. The Chi-square test was used to check whether the

144 genotype and allele distributions of the six SNPs were significantly different between males and

145 females. For each SNP, Hardy-Weinberg Equilibrium (HWE) was calculated with the goodness-

146 of-fit Chi-square test. $P<0.05$ was considered statistically significant. Binary logistic regression

147 analysis was used to detect associations between the genotypes of the six SNPs in the

148 *APOA1/C3/A4/A5-ZPR1-BUD13* gene cluster (in Dominant Model) and dyslipidemia adjusted for

149 sex (adjusted only in the overall group), age, BMI and waist circumference in the overall, male

150 and female groups. We set hypercholesterolemia, hypertriglyceridemia, high LDL cholesterolemia

151 and reduced HDL cholesterolemia as dependent variables, while genotypes, sex (only in the overall

152 group), age, BMI and waist circumference were set as independent variables and entered as

153 method. The strength of any evident association was explored by calculating odds ratios together

154 with their 95% confidence intervals (CI), and P values of no more than 0.008 after Bonferroni

155 Correction were considered statistically significant. All analyses were conducted using SPSS 24.0.

156 Linkage disequilibrium and haplotype analyses were performed with the SNPStats program

157 (http://bioinfo.iconcologia.net/SNPStats)(Sole et al. 2006) and Haploview software(Barrett et al.

158 2005).

Results

Subject characteristics and distributions of genotype and allele

161 The baseline characteristics of the subjects stratified by genders were shown in Table 1. No

162 difference was observed between males and females in terms of BMI, but the average age and

163 waist circumference were greater in males than females. In addition to the percentage of subjects

164 with hypercholesterolemia, there were significant differences in the percentages of subjects with

165 hypertriglyceridemia, high LDL, reduced HDL and dyslipidemia between males and females.

166 There were 2264 participants without dyslipidemia while the numbers of participants with one to

167 four type of dyslipidemia were 763, 623 ,184 and 16, respectively. The top five types of

168 dyslipidemia (and the number of participants with each type) were as follows:

169 hypertriglyceridemia (425), hypertriglyceridemia + reduced HDL cholesterolemia (397), reduced

170 HDL cholesterolemia (220), hypercholesterolemia + high LDL cholesterolemia (126) and

171 hypertriglyceridemia + hypercholesterolemia + high LDL cholesterolemia (107).

172 The genotype distributions of the six SNPs in the *APOA1/C3/A4/A5-ZPR1-BUD13* gene

173 cluster conformed to HWE in the overall group (Table S1). The allele distribution of one SNP

174 (rs651821) was different between males and females, and the genotype and allele distributions of

175 the six SNPs were shown in Table S1. Genotype distributions and allele frequencies of

176 dyslipidemia and normal groups were shown in Table S2.

177 **Association between SNPs and dyslipidemia**

178 In the overall group, logistic regression analysis revealed that dyslipidemia was associated

179 with three SNPs (rs5072, rs5104 and rs651821) after adjusting for sex, age, BMI and waist

180 circumference (Table 2). In the male group, rs651821 was found to be associated with

181 hypertriglyceridemia (OR=1.78, 95% CI=1.41-2.26) and low-HDL cholesterolemia (OR=1.61,

182 95% CI=1.27-2.05). Similar results were observed in the female group.   However, we found that

183 rs5072 was associated with hypertriglyceridemia (OR=1.39, 95% CI=1.09-1.76) in the female

184 group (Table 2). The association between the numbers of risk alleles and dyslipidemia was shown

185 in Table S3.

186 **Linkage disequilibrium (LD) and haplotype analyses**

187 The pattern of pairwise linkage disequilibrium (LD) between the SNPs of the

188 *APOA1/C3/A4/A5-ZPR1-BUD13* gene cluster was shown in Figure 1. Rs10488698, rs2075294

189 and rs651821 were located in block 1, while rs5104, rs5128 and rs5072 were located in block 2

190   after choosing the cut-off value of 0.75 for D'. The haplotype analysis results were shown in Table

191   3. People carrying haplotypes 2 and 3 presented an increased risk of dyslipidemia in the total

192   sample and the female and male groups. The association between haplotypes in blocks and

193   different types of dyslipidemia stratified by sexes was explored. We found that subjects with

194   haplotype CGC of block1 exhibited a higher risk of developing hypertriglyceridemia and reduced

195   HDL cholesterolemia in both sexes. In males, subjects carrying haplotype GCT of block 2

196   presented a higher risk of developing hypertriglyceridemia and reduced HDL cholesterolemia;

197   however, these results were not observed in females. Details were shown in Table S4.

198   **Discussion**

199   The study applied a large sample design to study the association between the

200   *APOA1/C3/A4/A5-ZPR1-BUD13* gene cluster gene polymorphisms and dyslipidemia. The

201   participants in this study were enrolled from a representative community-based population. To the

202   best of our knowledge, this is the first study to analyze the association of this gene cluster with

203   dyslipidemia in a sex-specific pattern in northeast China.

204   The *APOA1/C3/A4/A5* gene cluster is a well-studied gene cluster. Suarez-Sanchez F et al.

205   found that there was a significant association between *APOA1* rs5072 and TG in Mexican

206   children(Suarez-Sanchez et al. 2017), and in an Indian study(Pranavchand & Reddy 2017),

207   Pranavchand R concluded that rs5072 was also associated with increased TG; both of these

208   findings were similar to our results. Pranavchand R(Pranavchand & Reddy 2017) found that the

209   genotypic and allelic frequencies of rs5072 exhibited no significant differences between cases and

210   controls; however, our study indicated that there was an association between them in females. One

211   explanation for the difference between these two studies could be that they were conducted in

212   people of different ethnicities and ages. A recent exome-wide association study (EWAS)(Yamada

213   et al. 2017) performed in a Japanese population indicated that *APOA4* rs5104 located in this gene

214   was associated with the serum TG concentration. A genome-wide association study (GWAS)

215   conducted in Chinese people(Zhou et al. 2013) showed that rs651821 presented a strong

216   association with TG levels. Cha S et al.(Cha et al. 2014) drew the conclusion that subjects carrying

217 the variant allele of this SNP exhibited a higher risk of developing low-HDL cholesterolemia than

218 noncarriers in both genders in Koreans, which was consistent with our findings. In our study,

219 haplotype analysis showed that participants carrying the CGC haplotype of block 1 presented a

220 higher risk of developing hypertriglyceridemia (OR=1.76, 95% CI=1.59-1.96) and reduced HDL

221 (OR=1.80, 95% CI=1.59-2.03) than those carrying the CGT haplotype, which revealed that the T

222 allele of rs651821 was associated with a higher risk of hypertriglyceridemia and reduced HDL.

223 The MAFs of rs5072, rs5128, rs5104 and rs651821 in our study were 0.3060, 0.2966, 0.2995, and

224 0.2406, respectively. These results were similar to the frequencies identified in the southern Han

225 Chinese population in the 1000 Genomes Project, which were 0.3190, 0.3190, 0.3571 and 0.2714.

226 Compared with the frequencies observed in American subjects (0.0656, 0.0492, 0.1311 and

227 0.1639), British subjects (0.1099, 0.1209, 0.1648 and 0.0714) and other ethnicities, the frequencies

228 determined in our study were markedly different. Ethnicity may be critically important in studying

229 the association between SNPs and dyslipidemia. We used Polyphen to predict the influence of two

230 missense mutations (*APOA4* rs5014 and *BUD13* rs10188698) on the resultant proteins and found

231 that there was no significant influence on protein function. We also observed that these two SNPs

232 were not associated with any types of dyslipidemia.

233   At present, studies on *BUD13-ZPR1* gene polymorphisms focus on the association with lipid-

234 related diseases. *BUD13* and *ZPR1* were found to be associated across anatomical categories of

235 coronary artery disease in an Indian study(Pranavchand et al. 2017). Another study(Lin et al. 2016)

236 performed in a Taiwanese population indicated that *BUD13* may contribute to the risk of metabolic

237 syndrome, and *BUD13* rs623908 was shown to be significantly associated with high TG, low HDL,

238 and HDL levels. Among Chinese individuals(Xu et al. 2018), a strong association between

239 *BUD13-ZPR1* rs964184 and coronary heart disease was found, and both gender and age had great

240 impacts on the association of the rs964184 polymorphism with coronary heart disease. Another

241 study(Ueyama et al. 2015) indicated that rs964184 was significantly associated with the prevalence

242 of metabolic syndrome. In addition, there have been studies showing that that *ZPR1* contributed

243 to the risk of type 2 diabetes mellitus(Guan et al. 2016; Tokoro et al. 2015). Due to the association

244   of these two genes with lipid-related diseases, we conjecture that *BUD13* and *ZPR1* gene
245   polymorphisms may contribute to the risk of dyslipidemia.

246   In our study, we obtained the novel finding of sex-specific differences between the
247   *APOA1/C3/A4/A5-ZPR1-BUD13* gene cluster gene polymorphisms and dyslipidemia. These
248   differences could be partially explained by differences in sex between males and females.
249   Menopause could change the lipid profile by reducing HDL-C and increasing TG, TC and LDL-
250   C(Reddy Kilim & Chandala 2013). However, after menopause, healthy females were prone to
251   become more insulin resistant and gain total body and intra-abdominal fat(Milewicz et al. 2001).
252   Additionally, females with polycystic ovary syndrome (PCOS) usually become overweight or
253   obese, especially abdominally obese(Wu & von Eckardstein 2003). Accumulation of body and
254   central fat and decreased insulin resistance are associated with TG, HDL-C and LDL-C and may
255   therefore alter lipid homeostasis, respectively(Ferrannini et al. 2007). Consequently, mechanisms
256   underlying sex-specific differences between the gene cluster and dyslipidemia are complex and
257   should be further studied. We also found that the associations of the SNPs with dyslipidemia were
258   different when the total sample, males and females were considered separately. We speculated that
259   these associations may be influenced by sex and *P* values we set, since some *P* values were
260   between 0.008 and 0.05. There are some limitations of our study that must be recognized. In each
261   gene, we selected only one tag SNP with a MAF > 5% reported in published articles. We may have
262   ignored some SNPs with low MAFs or important functions in the *APOA1/C3/A4/A5-ZPR1-*
263   *BUD13* gene cluster. In addition, dyslipidemia is influenced not only by genetic factors but also
264   by diet, exercise and other environmental factors. We adjusted only sex, age, BMI and waist
265   circumference in our study. Consequently, more environmental factors need to be recorded and
266   adjusted in future studies, and the effects and mechanisms of SNPs in relation to gene expression
267   and protein expression warrant further study.

268   **Conclusion**

269   In conclusion, we analyzed and assessed the association between *APOA1/C3/A4/A5-ZPR1-*
270   *BUD13* gene cluster gene polymorphisms and dyslipidemia between sexes. We not only obtained

271 several results consistent with those reported based on previous studies but also found one SNP

272 (rs5072) was different between males and females, providing new insight into the mechanisms of

273 dyslipidemia in different genders.

274 **Acknowledgments**

275   We are grateful to the Jilin Provincial Health Department and the Chinese Jilin Provincial

276 Center for Disease Control and Prevention for supporting our project.

Basic characteristics and distribution of dyslipidemia of included subjects

1   Table 1 Basic characteristics and distribution of dyslipidemia of included subjects

Characteristics	Total (n=3850)	Male (n=1927)	Female (n=1923)	P
Age (year)	49.54(9.58)	49.93(9.75)	49.16(9.39)	**0.013**
Waist (cm)	82.73(11.22)	84.74(11.25)	80.72(10.83)	**<0.001**
BMI (kg/m^2)	24.40(3.96)	24.38(3.93)	24.42(4.00)	0.734
Hypertriglyceridemia, n (%)	1110(28.8)	664(34.5)	446(23.2)	**<0.001**
Hypercholesterolemia, n (%)	444(11.5)	214(11.1)	230(12.0)	0.406
High LDL, n (%)	352(9.1)	145(7.5)	207(10.8)	**<0.001**
Reduced HDL, n (%)	719(18.7)	450(23.4)	269(14.0)	**<0.001**
Dyslipidemia, n (%)	1586(41.2)	880(45.7)	706(36.7)	**<0.001**

2   Note:

3   BMI, body mass index

4   Means (standard deviation) for age, waist and BMI, a P value in bold indicated differences were

5   significant between males and females ($P<0.05$).

Association between genotypes of the six SNPs and dyslipidemia stratified by genders

Table 2 Association between genotypes of the six SNPs and dyslipidemia stratified by genders

SNPs	Hypertriglyceridemia (n=1110) OR (95% CI)[a]	Hypercholesterolemia (n=444) OR (95% CI)	High LDL (n=352) OR (95% CI)	Reduced HDL (n=719) OR (95% CI)

2 Note:

3 SNP, single nucleotide polymorphism

4 BMI, body mass index

5 OR, odds ratio

6 CI, confidence interval

7 ORs (95% CI) were shown in bold if corresponding *P* values were no more than 0.008 (0.05/6).

8 The genetic model in this association analysis was the Dominant Model.

9 (a) ORs and 95% CI were adjusted for sex, age, waist circumference and BMI in the overall group; ORs and 95% CI were adjusted for

10 age, waist circumference and BMI in the male and female groups.

Association between *APOA1/C3/A4/A5-ZPR1-BUD13* gene cluster haplotypes and the risk for dyslipidemia

3 Note:
4 SNP, single nucleotide polymorphism
5 BMI, body mass index
6 OR, odds ratio
7 CI, confidence interval
8 (a) SNPs are as follows: 1, rs5072; 2, rs5104; 3, rs5128; 4, rs651821; 5, rs2075294; 6, rs10488698.
9 (b) ORs were adjusted for sex, age, BMI and waist circumference in the overall group and were
10 adjusted for age, BMI and waist circumference in males and females.
11 (c) *P* values of less than 0.008 were considered to be significant after Bonferroni correction and
12 were presented in bold.
13 (d) Rare: haplotypes with frequencies<0.01.

Figure 1

Linkage disequilibrium analysis of six SNPs

The value of D' chosen as cut-off for linkage disequilibrium was 0.75.
