ZBTB38 belongs to the zinc finger protein family and contains the typical BTB domains. As a transcription factor, ZBTB38 is involved in cell regulation, proliferation and apoptosis, whereas, functional deficiency of ZBTB38 induces the human neuroblastoma cell death potentially. To have some insight into the role of ZBTB38 in neuroblastoma development, high throughput RNA sequencing was performed using the human neuroblastoma cell line SH-SY5Y with the deletion of ZBTB38. In the present study, 2,438 differentially expressed genes (DEGs) in ZBTB38^{-/-} SH-SY5Y cells were obtained, 83.5% of which was down-regulated. Functional annotation of the DEGs in the Kyoto Encyclopedia of Genes and Genomes database revealed that most of the identified genes were enriched in the neurotrophin TRK receptor signaling pathway, including PI3K/Akt and MAPK signaling pathway. we also observed that ZBTB38 affects expression of CDK4/6, Cyclin E, MDM2, ATM, ATR, PTEN, Gadd45 and PIGs in the p53 signaling pathway. In addition, ZBTB38 knockdown significantly suppresses the expression of autophagy-related key genes including PIK3C2A and RB1CC1. The present meeting provides evidence to molecular mechanism of ZBTB38 modulating neuroblastoma development and targeted anti-tumor therapies.

Transcriptome Profiling Reveals the Role of ZBTB38 Knock-down in Human Neuroblastoma

26 ABSTRACT

27 ZBTB38 belongs to the zinc finger protein family and contains the typical BTB domains. As a
 28 transcription factor, ZBTB38 is involved in cell regulation, proliferation and apoptosis, whereas,
 29 functional deficiency of ZBTB38 induces the human neuroblastoma cell death potentially. To
 30 have some insight into the role of ZBTB38 in neuroblastoma development, high throughput
 31 RNA sequencing was performed using the human neuroblastoma cell line SH-SY5Y with the
 32 deletion of ZBTB38. In the present study, 2,438 differentially expressed genes (DEGs) in
 33 ZBTB38^{-/-} SH-SY5Y cells were obtained, 83.5% of which was down-regulated. Functional
 34 annotation of the DEGs in the Kyoto Encyclopedia of Genes and Genomes database revealed
 35 that most of the identified genes were enriched in the neurotrophin TRK receptor signaling
 36 pathway, including PI3K/Akt and MAPK signaling pathway. we also observed that ZBTB38
 37 affects expression of CDK4/6, Cyclin E, MDM2, ATM, ATR, PTEN, Gadd45 and PIGs in the
 38 p53 signaling pathway. In addition, ZBTB38 knockdown significantly suppresses the expression
 39 of autophagy-related key genes including PIK3C2A and RB1CC1. The present meeting provides
 40 evidence to molecular mechanism of ZBTB38 modulating neuroblastoma development and
 41 targeted anti-tumor therapies.

42 INTRODUCTION

43 Neuroblastoma (NB) is an embryonal malignant tumor that originated from neural crest cells of
 44 the sympathetic nervous system. It is the most common extracranial solid tumor in children,
 45 accounting for 8-10% of pediatric malignancies (Castel et al. 2013; Schulte et al. 2013). This
 46 disease is highly malignant and progresses rapidly—most of the patients would have been at the
 47 advanced stage upon diagnosis when conventional radiotherapy and chemotherapy would have
 48 little efficacy, so their survival rate is very low (Bagatell & Cohn 2016). In recent years, new
 49 therapeutic methods including hematopoietic stem cell transplantation and biological
 50 immunotherapy have been employed to treat relapsed or refractory NB, but the efficacy is still
 51 limited (Binkhathlan & Lavasanifar 2013; Han & Wang 2015). Drug resistance has been
 52 recognized as the key obstacle to reach a satisfactory outcome (Castel et al. 2013), while
 53 induction of programmed death of the cancer cells by targeted gene therapy shows great potential
 54 in improving the cure rate and long-term survival of NB patients, especially those with higher
 55 risks.

ZBTB38 belongs to the zinc finger and BTB domain-containing protein family. Most members of the family, as transcription factors, bind to specific DNA sequences and regulate the transcriptional activity of target genes (Sasai et al. 2005; Stogios et al. 2005). In addition, the family members also involve in various intracellular signal transduction pathways via recognizing and interacting with other proteins, thereby playing important roles in the transcriptional repression, DNA damage, tumorigenesis, and cell proliferation, differentiation, and apoptosis (Lee et al. 2010; Matsuda et al. 2008; Nishii et al. 2012). At least 49 ZBTB proteins are encoded in the human genome, most of which are nuclear proteins (Lee & Maeda 2012). Among the predicted BTB domain-containing proteins encoded by the human genome, only several of them have been functionally characterized (Cai et al. 2012; Matsuda et al. 2008). No relevant studies have been reported concerning the effect of ZBTB38 in human neuroblastoma.

Transcriptomic studies are developing rapidly over recent years, which, contrary to the studies on an individual gene, enable the investigation on the altered expression of differentially expressed genes (DEGs) on the level of whole protein-coding or non-coding RNAs in cells or tissues of the body. Besides, it can also provide information of the relationship between transcriptional regulation and the protein functions in the whole genome under specific conditions (Reimann et al. 2014; Zhao et al. 2011). Next-generation sequencing (NGS) technology offers important technical support for the annotation and quantification of transcriptomes. The major strength of this technique lies in its high-throughput and high sensitivity for transcript abundance, providing throughout understanding of the transcriptional information of the genome in a comprehensive manner and valuable resources for studies investigating therapeutic biomarkers of cancer (Chang et al. 2015; Li et al. 2014).

Therefore, in the present study, a high-throughput transcriptome sequencing approach was adopted to investigate the transcriptome profiles of neuroblastoma cells in which the expression of ZBTB38 gene was down-regulated, thus revealing potential biomarkers associated with anti-tumor therapies in neuroblastoma.

MATERIALS & METHODS

Cell culture and standard assays

SH-SY5Y cells were purchased from American Type Culture Collection (Rockville, MD, USA) and cultured in Dulbecco's modified Eagle's medium supplemented with 10% fetal bovine serum and penicillin–streptomycin. Transient transfections, quantitative real-time polymerase

chain reaction (qRT-PCR) and western blotting were performed as described previously (Cai et al. 2012; Cai et al. 2017). The primers used in qRT-PCR and siRNA suppression assays are listed in supplemental Table S1. Cell viability was tested using the CCK-8 assay. The absorbance of each well was measured at 450 nm on a microplate reader. The proliferation rate was defined in terms of the percentage of each group of surviving cells compared with the untreated group for both cell lines.

RNA Preparation and library construction for transcriptome sequencing

Transcriptome high-throughput sequencing was performed in the control group (SH-SY5Y cells transfected with liposome alone, Samples-ID: T04, T05, T06) and the treatment group (SH-SY5Y cells transfected with ZBTB38 siRNA, Samples-ID: T01, T02, T07). Total RNA was isolated from SH-SY5Y cells using TRIzol and the pure-link RNA mini kit (ThermoFisher Scientific, Waltham, MA, USA) according to manufacturer's instructions. RNA purity was checked using the NanoPhotometer spectrophotometer (IMPLEN, CA, USA). RNA concentration was measured using the Qubit RNA Assay Kit in Qubit 2.0 Fluorometer (Life Technologies, CA, USA). RNA integrity was assessed using the RNA Nano 6000 Assay Kit of the Agilent Bioanalyzer 2100 system (Agilent Technologies, CA, USA).

In total, 2 µg RNA per sample was used as input material for RNA sample preparations. This study included two groups of three biological replicates. Sequencing libraries were generated using a NEBNext Ultra™ RNA Library Prep Kit for Illumina (NEB, USA), and index codes were added to attribute sequences to each sample. Fragmentation was performed using divalent cations under elevated temperature in NEBNext First Strand Synthesis Reaction Buffer (5×). First-strand cDNA was synthesized using random hexamer primer and M-MuLV Reverse Transcriptase (RNase H). Second-strand cDNA synthesis was subsequently performed using DNA Polymerase I and RNase H. Remaining overhangs were converted into blunt ends via exonuclease/polymerase activities. After the adenylation of 3' ends of DNA fragments, NEBNext Adaptor with a hairpin loop structure was ligated to prepare for hybridization. The library fragments were purified using AMPure XP system (Beckman Coulter, Beverly, USA). Then, 3 µl USER Enzyme (NEB, USA) was used with size-selected, adaptor-ligated cDNA at 37°C for 15 min, followed by 5 min at 95°C before PCR. Following this, PCR was performed with Phusion High-Fidelity DNA polymerase, universal PCR primers, and index (X) Primer. Finally, PCR products were purified (AMPure XP system), and library quality was assessed using the Agilent Bioanalyzer 2100 system. The clustering of the index-coded samples was performed on a cBot Cluster Generation System using the TruSeq PE Cluster Kit v4-cBot-HS (Illumia).

Following cluster generation, the library preparations were sequenced on an Illumina Hiseq 2500 platform, and paired-end reads were generated.

Data and Statistical Analysis

Cancer genomics analysis

we downloaded the mRNA expression data from TCGA ([The Cancer Genome Atlas](#)) database and systematically evaluated the expression of ZBTB38 and correlation with patients' survival in 511 brain lower grade glioma samples of the TCGA database.

Quality control

Raw reads of fastq format were firstly processed through in-house perl scripts. In this step, clean reads were obtained by removing reads containing adapter, reads containing ploy-N and low quality reads from raw reads. At the same time, Q20, Q30, GC-content and sequence duplication level of the clean reads were calculated. All the downstream analyses were based on clean reads with high quality (Ewing & Green 1998; Ewing et al. 1998). The clean data of this article are publicly available in the NCBI Sequence Reads Archive (SRA) with accession number SRP150042.

Comparative analysis

The adaptor sequences and low-quality sequence reads were removed from the data sets. Raw sequences were transformed into clean reads after data processing. These clean reads were then mapped to the reference genome sequence. Only reads with a perfect match or one mismatch were further analyzed and annotated based on the reference genome. Tophat2 tools soft were used to map with reference genome (Kim et al. 2013; Langmead et al. 2009). Reference genome download address: ftp://ftp.ensembl.org/pub/release-80/fasta/homo_sapiens/.

Gene functional annotation

The assembled sequences were compared against the NR ([NCBI non-redundant protein sequences](#)), Pfam ([Protein family](#)), KOG/COG ([Clusters of Orthologous Groups of proteins](#)), Swiss-Prot ([A manually annotated and reviewed protein sequence database](#)), KO ([KEGG Ortholog database](#)), and GO ([Gene Ontology](#)) databases with an E-value $\leq 10^{-5}$ for the functional annotation. The Blast2GO program was used to obtain GO annotation of unigenes including molecular function, biological process, and cellular component categories (Gotz et al. 2008).

Differential expression analysis

Differential expression analysis of the two conditions was performed using the DEGseq R package (Robinson et al. 2010). The P-values obtained from a negative binomial model of gene expression were adjusted using Benjamini and Hochberg corrections to control for false discovery rates (Anders & Huber 2010). Genes with an adjusted P-value < 0.05 were considered to be differently expressed between groups. DEG expression levels were estimated by fragments per kilobase of transcript per million fragments mapped (Florea et al. 2013). The formula is shown as follow:

$$FPKM = \frac{\text{cDNA Fragments}}{\text{Mapped Fragments(Millions)} \times \text{Transcript Length(kb)}}$$

GO enrichment and KEGG pathway enrichment analysis

GO enrichment analysis of the differently expressed genes (DEGs) was implemented in the “Goseq” package in R based on a Wallenius non-central hyper-geometric distribution, which can adjust for gene length bias in DEGs (Young et al. 2010).

KEGG is a database for understanding high-level functions and utilities of biological systems through large-scale molecular datasets generated by genome sequencing and other high-throughput experimental technologies (<http://www.genome.jp/kegg/>) (Kanehisa et al. 2008). We used the KOBAS software to test for the statistical enrichment of differentially expressed genes in KEGG pathways. KEGG enrichment can identify the principal metabolic pathways and signal transduction pathways of DEGs (Mao et al. 2005).

DEGs quantitative real-time pcr (qRT-PCR) verification

For validation of the transcriptome result, we subjected three significantly differential expressed unigenes on related pathways to qRT-PCR analysis. Redundant RNA from the cDNA library preparation was used to perform reverse transcription according to the Invitrogen protocol. quantitative real-time polymerase chain reaction (qRT-PCR) were performed as described previously (Zhang et al. 2017). The primers used in qRT-PCR suppression assays are listed in *Table S1*.

Statistical analysis

All data were reported as mean ± standard deviation and analyzed using one-way analysis of variance in SPSS v.17.0. Statistical tests were performed with the Kruskal–Wallis and Mann–Whitney U-tests. A least significant difference test was used for comparisons between groups. A P-value < 0.05 was considered statistically significant.

RESULTS

Variation of ZBTB38 in tumors

According to the statistical analysis of the TCGA database resources, we found that the expression changes of ZBTB38 gene are closely related to the occurrence of 20 kinds of cancers, and especially the most remarkable down-regulated expression in UCEC (Uterine corpus endometrial carcinoma) and CESC (Cervical squamous cell carcinoma and endocervical adenocarcinoma) (Fig. 1). And we also uncover here that low expression of ZBTB38 was associated with improved the prognosis of the LGG (Brain lower grade glioma) patients (Fig. 2), suggesting that these changes are closely related to neuronal tumors.

Neuroblastoma cell proliferation and viability after down-regulated of ZBTB38 expression

To investigate the importance of ZBTB38 in the process of neuronal tumors, three pairs of siRNAs named siRNA1, siRNA2, and siRNA3, were designed to suppress expression of ZBTB38 in human neuroblastoma cells SH-SY5Y. The protein level of ZBTB38 was decreased significantly ($p < 0.05$) at 24 h after transfection (Fig. 3A and B), and furthermore, siRNA3 worked best for the suppression. No significant difference in cell proliferation and viability was observed among the initial phases of each group after culture by transient transfection ($p > 0.05$). From 12–72 h, the ZBTB38^{-/-} SH-SY5Y group showed significantly lower cell proliferation and viability than the control group ($p < 0.05$) (Fig. 3C and D).

Quality control and yield statistics of transcriptome sequencing data

A total of 47.05 Gb clean data were obtained through the transcriptome sequencing of SH-SY5Y cells, with at least 6.12 Gb and a $\geq 89.30\%$ Q30 percentage for each sample (Table 1). Efficiency of sequence alignment referred to the percentage of mapped reads in the clean reads, which reflected the utilization of transcriptome sequencing data. Statistical analysis of the alignment results showed that the efficiency of read alignment for the reads of each sample and the reference genome ranged between 79.42% and 81.92% (Table 1), which guaranteed that the selected reference genome assembly was qualified for data analysis.

Qualified transcriptome libraries are a major requisite for transcriptome sequencing. To ensure the quality of the libraries, quality of the transcriptome sequencing libraries was evaluated from three different perspectives:

(1) Randomicity of mRNA fragmentation and the degradation of mRNA were evaluated by examining the distribution of inserted fragments in genes. As shown in Figure S1, The degradation of mRNAs was relatively low in the 6 groups of samples.

(2) The dispersion degree of the inserted fragment length directly reflected the efficiency of magnetic bead purification during library preparation. Simulated distribution of the inserted fragment length for each sample showed only single-peak pattern, indicating a high purification rate (*Fig. S2*).

(3) With the increase of sequencing data, the number of DEGs tended to saturate, as shown in *Figure S3*, which confirmed that the data were sufficient and qualified for the subsequent analysis.

DEG and DEGs Function annotation

To acquire the comprehensive genetic information of ZBTB38^{-/-} SH-SY5Y cells, the unigenes were blasted against the NR, Swiss-Prot, GO, COG, KOG, Pfam, KEGG database resources to identify the functions of all of the unigene sequences. All of DEGs were annotated to genes having known functions in the indicated databases based on the sequences with the greatest similarity. DEseq was used to analyze the DEGs derived from the two groups of cells to obtain a DEGs set. Finally, a total of 2,036 (83.5%) down-regulated DEGs and 402 (16.5%) up-regulated DEGs were selected. The number of DEGs annotated in this gene set was shown in *Table 2*. A total of 2,258 (93.4%) DEGs were annotated successfully by GO annotation. These annotated DEGs were classified into the next terms of three ontologies: BP (biological process), CC (cellular component) and MF (molecular function). The distribution of unigenes is shown in *Figure 4*. Among the “Biological Process”, a high percentage of genes were classified into Cellular Process (1,924 unigenes, 85.2%). Within the cellular component category, the majority of genes were assigned into Cell Part (2,145 unigenes, 95%) . For the molecular function, most of genes were involved in “Binding” (1,949 unigenes, 86.3%). The greatest number of annotated unigenes were involved in Biological Process. The results of the topGO functional enrichment analyses of DEGs indicated that the most significantly enriched GO terms focus on “neurotrophin TRK receptor signaling pathway” (*Table S2*).

The unigenes was blasted against the COG database in order to orthologously classify gene products. COG classification statistical results of DEGs were shown in *Figure 5*. In addition to “General function prediction only”, “Replication, recombination and repair” accounted for the largest proportion of unigenes (180 DEGs, 13.06%), followed by “Transcription” (133 DEGs, 9.65%), “Signal transduction mechanisms”(128 DEGs, 9.29%), “Translation, ribosomal structure and biogenesis” (80 DEGs, 5.81%), “Posttranslational Modification, Protein Turnover and Chaperones” (79 DEGs, 5.73%), “cell cycle control, cell division, and chromosome partitioning” (44 DEGs, 2.98%). According to the annotation results of the DEGs KEGG database, the largest proportion of the unigenes were involved in the “MAPK signaling pathway” and “PI3K-Akt signaling pathway” of “Environmental Information Processing”(Figure 6).

Based on the results above, a large number of DEGs were screened after a comparative analysis of relevant databases. Meanwhile, functional annotation was also carried out that was crucial for the further understanding of the cellular functions of ZBTB38 gene as a transcription factor.

Detection of candidate genes and analysis of the results of Real-time quantitative PCR

Taking FPKM as a measure for the level of transcripts or gene expressions, DEGs in the p53 signaling pathway, including CDK4/6, Cyclin E, MDM2, ATM, ATR, PTEN, were down-regulated, and Gadd45 and PIGs were up-regulated. Top 20 down-regulated unigenes associated with autophagy were selected (*Table S3*), among which PIK3C2A was the most down-regulated one, followed by RB1CC1 gene. In summary, the transcription factor ZBTB38 is involved in the process of protein synthesis and also, as a positive regulatory factor, in the occurrence of autophagy directly.

To validate the sequencing results obtained by RNA-seq, real-time quantitative PCR was performed on three candidate genes, including PIK3C2A, RB1CC1, ATM, related to the mTOR signaling pathway. The result showed that the expression of these candidate genes was significantly decreased in the ZBTB38^{-/-} cells compared to control group, which was similar to the RNA-seq data (*Fig. 7*). The result verified the reliability of the transcription sequencing results.

DISCUSSION

Transcriptomic studies are developing rapidly over recent years. Based on the information of the whole mRNAs obtained in one cell or tissue, transcriptomic studies provide data on the expression regulation systems and protein functions of all genes. NGS facilitates the deep sequencing of whole cancer genomes for the discovery of novel therapeutic biomarkers, helping to consequently build a solid foundation for comprehensive studies of cancer pharmacogenetics. Furthermore, NGS allows for detailed analyses of the whole epigenome and transcriptome, thus profoundly revealing the multilevel regulation networks of the human genome (McGettigan 2013; Wang et al. 2009; Young et al. 2010). Remarkably, the large amount of data information of gene expression profiles revealed by transcriptome sequences have provided valuable resources for studies investigating therapeutic biomarkers of cancer.

Genomic instability is an important factor in the early stages of cell carcinogenesis. Error-prone DNA repair and the accumulation of abnormal DNA after repair are the main causes of genomic instability (Lord & Ashworth 2012). Strict regulation of gene transcription is an essential factor to maintain genomic stability (Kakarougkas et al. 2014). According to the statistical analysis of

the TCGA database, ZBTB protein family is mainly involved in the regulation of the expression of target genes. Besides, the amplification, deficiency and/or mutation of most genes in ZBTB family occurs in different types of tumors (Jardin et al. 2007; Maeda et al. 2007; Phan & Dalla-Favera 2004). Among them, the expression changes of ZBTB38 gene are closely related to the occurrence of 20 kinds of cancers (*Fig. 1A*), and there exists significant different expression changes in different tumors, especially the most remarkable down-regulated expression in UCEC and CESC (*Fig. 1B and D*). In our study, the statistical analysis of the prognosis of the LGG patients exhibited a negative correlation with the expression change of ZBTB38 (*Fig. 2*), indicating great significant concerning the study of the effect of ZBTB38 expression changes on the occurrence and development of neuroma. However, there was no relevant report about the expression change of ZBTB38 in NBs. This study demonstrated for the first time in vitro that the knockdown of ZBTB38 seriously affected the proliferation of NB cells. Accordingly, it deserves further analysis regarding the biological function of ZBTB38 and relationship with clinical prognosis of NB.

Annotation of the function of the DEGs revealed that the most of DEGs after ZBTB38 knockdown enriched in neurotrophin TRK (tyrosine kinase receptor) receptor signaling pathway. Neurotrophic factors (NTs) are a class of factors that regulate neuronal development, differentiation, and function. NTs may activate two types of receptors, the high-affinity tyrosine kinase family TRK receptors and the low-affinity p75NTR (p75 neurotrophin receptor) receptor of the tumor necrosis factor receptor superfamily (Yang et al. 2016). NTs can initiate many complex signal transduction pathways by activating these two types of receptors and thus exert biological effects. In most cases, p75NTR is a ligand-activated apoptotic receptor, whose main biological effect is to induce neuronal apoptosis and activate the apoptotic signal transduction pathway JKN-p53-Bax (Redden et al. 2014). TRKs mainly activate two pathways: the PI3K-Akt signaling pathway that inhibit the production and activity of apoptotic proteins, and the MAPK signaling pathway that activate anti-apoptotic proteins to promote survival (Wong et al. 1999). In this study, the KEGG pathway enrichment analysis of differentially expressed genes revealed that DEGs were the most enriched genes in the MAPK and PI3K-Akt signaling pathways, and most of the DEGs were downregulated, so we speculated that ZBTB38 knockdown-induced reduction in viability and proliferation rate of SH-SY5Y cells may be closely related to these pathways, and plan to focus on key components of the DEGs in future studies, to clarify the molecular mechanism and to further evaluate the potential of ZBTB38 as a target gene to treated NB.

A key feature of neuroblastoma is that it is uniformly p53 wild-type at diagnosis with intact intrinsic and extrinsic apoptotic mechanisms, and direct inactivating p53 mutations are rare regardless of stage of treatment suggests that neuroblastoma has an innate requirement for

baseline p53 activity (Kim & Shohet 2009). In the present study, the KEGG pathway enrichment analysis of DEGs revealed that genes in the p53 signaling pathway, including CDK4/6, Cyclin E, MDM2, ATM, ATR, PTEN, were down-regulated, and Gadd45 and PIGs were up-regulated after the knockdown of ZBTB38 (*Fig. 8*). Both the CDK4/6-Cyclin D and the CDK2-Cyclin E complexes are the central links in cell cycle regulation via regulating the G1-S transitions in cells, and abnormal activation of the CyclinD-CDK4/6-INK4-Rb pathway, which is often observed in various malignancies, will lead to uncontrolled growth of cancer cells (Sawai et al. 2012; The et al. 2015; VanArsdale et al. 2015). In addition, members of the Gadd45 family serve as key regulatory genes in DNA damage repair pathway with p53 as the central link, and the upregulation of Gadd45 plays an important role in the regulation of G2/M cell cycle checkpoints and the maintenance of genomic stability, therefore to inhibit the cell transformation and the malignant progression of tumors (Wang et al. 1999). ATM and ATR belong to the inositol trisphosphate kinase family, both of which can be activated by DNA damage to phosphorylate the downstream substrates such as CHK1, CHK2, and p53. In addition, the down-regulation of both kinases may impair the downstream transmission of the molecular signals and inhibit the p53 activity (Abraham 2001; Matsuoka et al. 2007). MDM2 regulates the function of p53 via two approaches, i.e., mediating p53 degradation and inhibiting its transcriptional activity. As a negative feedback regulator of p53, the inhibited expression of MDM2 can enhance the transcriptional activity of p53 and inhibit tumorigenesis (Shangary & Wang 2009). PIGs is a target downstream gene of p53 for the regulation of apoptosis, which is critical for cell apoptosis by participating in the synthesis of reactive oxygen species and the regulation of oxidative stress (Jin et al. 2017; Lee et al. 2010). When ZBTB38 gene is knocked down, more PIGs are transferred into the nucleus where cell damage is repaired. Therefore, cellular response to DNA damage is increased and the p53 induced ROS production, ultimately promote the apoptosis of tumor cells. PTEN is a tumor suppressor gene with phosphatase activity. It is an upstream regulatory inhibitor of the PI3K/Akt signal transduction pathway. PTEN is often referred to as a “switch” molecule in the PI3K/Akt pathway due to its ability, which depends on its lipid phosphatase activity, to remove the phosphate group and participate in the regulation of cell activity. Once the expression of PTEN protein is reduced, the dephosphorylation of PIP3(the lipid product of PI3-kinaseis) decreased. Excessive PIP3 is subsequently accumulated in the cells and the PI3K/Akt signaling pathway is continuously activated, eventually leading to cell proliferation or uncontrolled apoptosis and finally the occurrence of various diseases (Bleau et al. 2009; Carnero et al. 2008). In summary, studies that interrogating the roles of ZBTB38 and p53 pathways in growth and apoptosis of NB cells and those involving intervention of specific signaling pathways may allow us to further understand the mechanisms of NB occurrence and progression, and thus better evaluate and control this pediatric malignancy.

Majority of the DEGs were enriched in the PI3K-Akt signaling pathway among all KEGG pathway enrichment categories, especially for those down-regulated genes, with most significance noted in PIK3C2A and RB1CC1. PIK3C2A is a member of the PI3Ks family and one of the key molecules in the signal transduction pathway of growth factors. It has been reported that the overexpressed PIK3C2A in cells induces the accumulation and assembly of clathrin, which mediates the transport of proteins between cell membranes and the network structure of the Golgi body via regulating the movement of microtubules (Dragoi & Agaisse 2015; Shi et al. 2016). RB1CC1 (also known as FIP200) is an interacting protein of the focal adhesion kinase family, with a molecular weight of 200kD. As documented in prior studies, autophagy induction is abolished in RB1CC1-deficient cells. RB1CC1 is an important regulatory protein that can acts on the autophagic initiation complex along with the ULK1 (Unc-51 like autophagy activating kinase) simultaneously. Besides, it is also a key autophagy initiation factor in the mTORC1-dependent signaling pathway (Ganley et al. 2009; Wang et al. 2011; Wei et al. 2009). Therefore, it is believed in our study that the autophagy regulation mechanism of the mTORC1-dependent signaling pathway is also inhibited after ZBTB38 knockdown. Orthologous assignments of gene products were carried out using the COG database. Corresponding statistical analysis of the results also indicated that the silencing of ZBTB38 gene affected the homeostasis of the whole cell, and as a transcriptional factor, ZBTB38 regulated the transcription of intracellular proteins and influenced the expression and transport of proteins in the downstream signaling pathways. The GO functional enrichment analyses of DEGs suggested that most of the genes were involved in “Binding” and “Catalytic Activity” of the molecular function between ZBTB38^{-/-} cells and the controls. Therefore, this also partially explained the biological functions of the key candidate genes enriched in KEGG pathway, i.e., all of them were specific binding DNAs or proteins that regulated the transcriptional activity of target genes and involved in various intracellular signaling pathways.

CONCLUSIONS

The functional knockdown of transcription factor ZBTB38 effectively inhibited proliferation and differentiation of NB cells, which may be largely attributed to significant inhibition of the neurotrophin TRK receptor signaling pathway. In addition, downregulation of ZBTB38 may also promote apoptosis of the NB cells by regulating key components of the p53 signaling pathway. Two DEGs closely related to autophagy initiation (PIK3C2A and RB1CC1) were significantly inhibited, suggesting that ZBTB38 downregulation also blocked autophagy, an important mechanism that protects the cells from programmed cell death, thus accelerating apoptosis of

tumor cells. The present meeting provides evidence to molecular mechanism of ZBTB38 modulating neuroblastoma development and targeted anti-tumor therapies.

ACKNOWLEDGEMENTS

This work was supported by the National Natural Science Foundation of China under Grant [NSFC31372207 and 81570094]; the Innovation Team of Scientific Research Platform in Anhui Province, a start-up Grant from Nanjing Agricultural University [804090].

Figure 1

Expression analysis of ZBTB38 gene in different tumors based on TCGA Database.

(A) The expression changes of ZBTB38 gene are closely related to the occurrence of 20 kinds of cancers; (B-D) ZBTB38 expression profiles based on top 4 cancer stages.

A

Cancer Distribution

B

C

D

E

Figure 2

Effect of ZBTB38 expression level on LGG patient survival.

Red and blue lines indicated high and low expression groups, respectively. $P = 0.02 < 0.05$ was considered to be statistically significant.

Figure 3

Proliferation and viability of ZBTB38 knockdown SH-SY5Y cells.

(A, B) SH-SY5Y cells were divided into two groups underwent control group and siRNA, respectively. cell lysates were collected for Western blot analysis on the 24 h after transfecting different sequences of ZBTB38 siRNAs (siRNA1, siRNA2 and siRNA3 indicate three different siRNA primers). Representative images of these assays are shown in (A) and quantitative data are shown in (B); β -actin was used as an internal control. SH-SY5Y cell proliferation (C) and viability (D) in different groups. * $p < 0.05$. Data are presented as means \pm SEM from at least 3 independent experiments. Control, SH-SY5Y cells treated with liposome alone; ZBTB38^{-/-}, SH-SY5Y cells transfected with ZBTB38 siRNA.

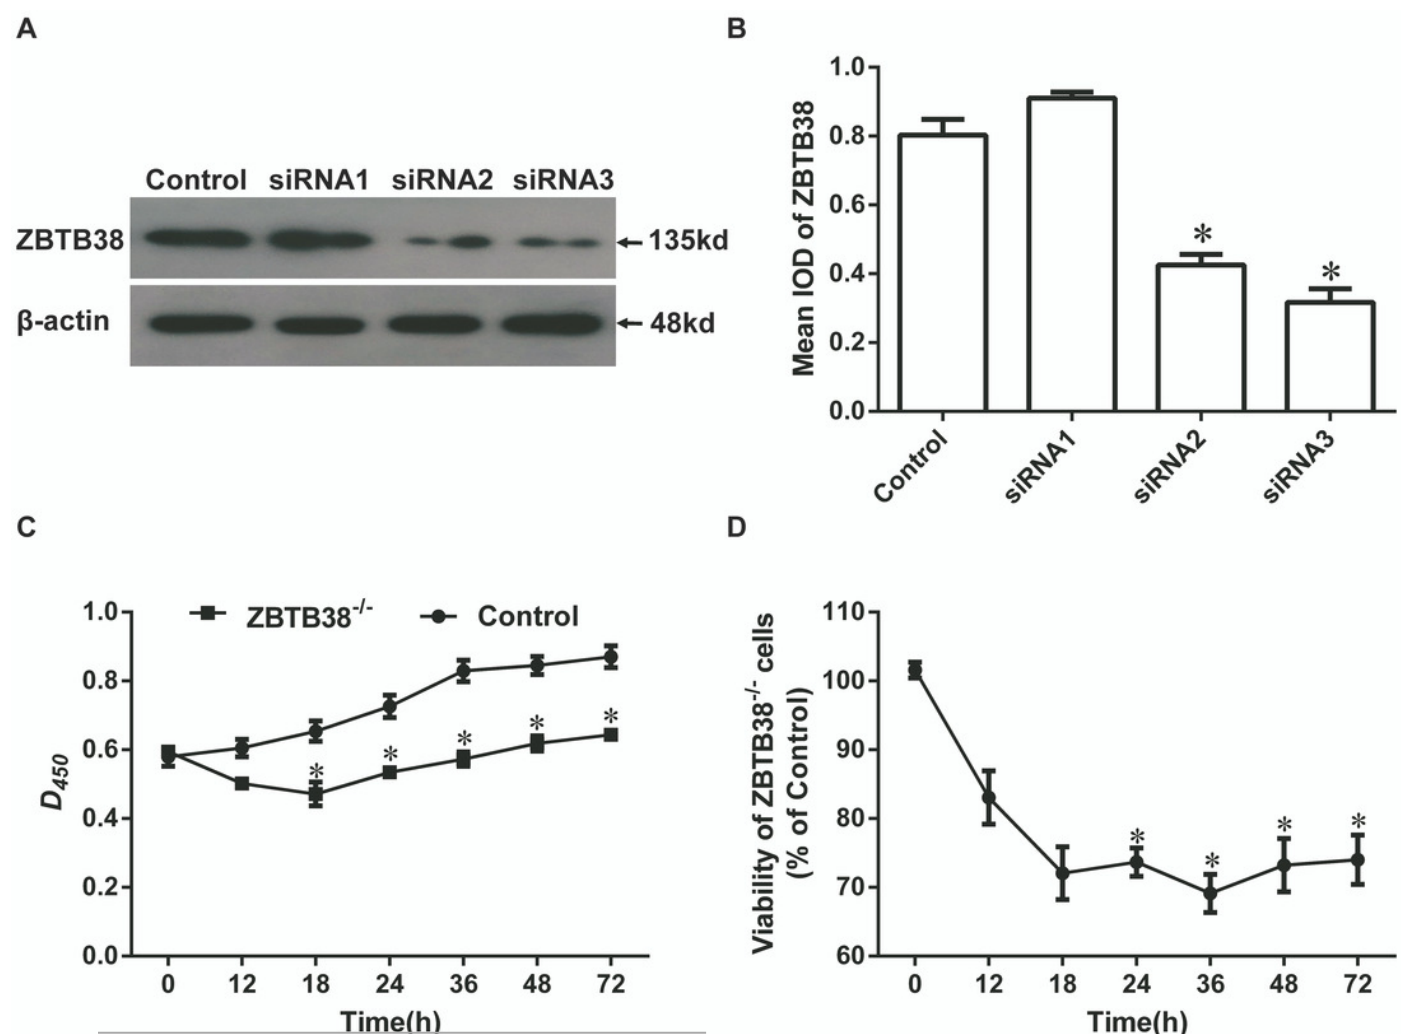

Figure 4

Gene function classification of all annotated unigenes by Gene Ontology.

The vertical axis represents the number of unigenes, and horizontal axis gives the specific GO sub-categories.

Figure 5

COG function classification of consensus sequence.

The vertical axis represents the frequency of unigenes classified into the specific categories, and horizontal axis gives the COG function classification.

Figure 6

DEG KEGG classification.

The vertical axis lists the various metabolic pathways, and horizontal axis gives the number of annotated genes in the pathways.

Figure 7

Differential expression analysis of candidate genes between ZBTB38^{-/-} and ZBTB38 SH-SY5Y cells.

(A) The result of qRT-PCR. (B) The result of RNA-seq.

Figure 8

KEGG pathway annotation map of differentially expressed genes in p53 signaling pathway.

Relative to the control group, the red labeled protein was associated with the up-regulated gene and the white labeled protein was associated with the down-regulated gene.

Table 1(on next page)

Summary of Sequence comparisons among sample sequencing data and selected reference genomes.

1

2 **Table 1. Summary of Sequence comparisons among sample sequencing data and selected reference genomes.**

Samples-ID	Total Reads	Mapped Reads	Uniq Mapped Reads	Multiple Map Reads	GC Content	%≥Q30
T01	41,320,306	32,993,483 (79.85%)	29,171,906 (70.60%)	3,821,577 (9.25%)	56.24%	89.44%
T02	53,706,092	42,655,511 (79.42%)	37,610,672 (70.03%)	5,044,839 (9.39%)	55.36%	89.45%
T04	54,889,928	44,964,104 (81.92%)	41,561,590 (75.72%)	3,402,514 (6.20%)	52.17%	90.04%
T05	50,160,236	40,559,313 (80.86%)	37,552,835 (74.87%)	3,006,478 (5.99%)	52.16%	90.25%
T06	62,721,676	50,526,963 (80.56%)	47,347,475 (75.49%)	3,179,488 (5.07%)	51.94%	90.05%
T07	54,693,534	43,544,178 (79.61%)	38,543,679 (70.47%)	5,000,499 (9.14%)	55.22%	89.30%

3 T01, T02, and T07 indicate the ZBTB38^{-/-} SH-SY5Y cells. T04, T05, and T06 indicate the control groups. Total Reads: Number of Clean Reads,
4 single-ended; Mapped Reads: Number of Reads aligned to the reference genome and percentage in Clean Reads; Uniq Mapped Reads: Match The
5 number of Reads to the unique position of the reference genome and the percentage of the Clean Reads; Multiple Map Reads: The number of
6 Reads aligned to multiple locations in the reference genome and the percentage of Clean Reads. GC content: The Clean Data GC content; ≥ Q30% :
7 The percentage of bases with a Clean Data quality value ≥ 30.
