Abstract

Gliomas are a very diverse group of brain tumors that are most commonly primary tumor and difficult to cure in central nervous system. It's necessary to distinguish low-grade tumors from high-grade tumors by understanding the molecular basis of different grades of glioma, which is an important step in defining new biomarkers and therapeutic strategies. We have chosen gene expression profile of GSE52009 from GEO database to detect important differential genes. GSE52009 contains 120 samples, including 60 WHO II samples and 24 WHO IV samples, were selected in our analysis. We used GEO2R tool to pick out differently expressed genes (DEGs) between low-grade glioma and high-grade glioma, and then we used The Database for Annotation, Visualization and Integrated Discovery (DAVID) to perform gene ontology (GO) analysis and Kyoto Encyclopedia of Gene and Genome (KEGG) pathway analysis. Furthermore, Cytoscape with Search Tool for the Retrieval of Interacting Genes (STRING) and Molecular Complex Detection (MCODE) plug-in were applied to achieve the visualization of protein-protein

interaction (PPI). We selected 15 hub genes with higher degree of connectivity, including TIMP1 and SAA1 and we used GSE53733 containing 70 glioblastoma samples to conduct Gene Set Enrichment Analysis on. In conclusion, DEGs and hub genes were demonstrated in our bioinformatics analysis, that they might be defined as new biomarkers for diagnosis and to guide the therapeutic strategies of glioblastoma.

1. Introduction

Gliomas are a very diverse group of brain tumors that are most commonly primary tumor and difficult to cure in central nervous system (Louis et al. 2016; Ostrom et al. 2017). Despite the multiple therapeutic strategies, including surgery, radiation, and chemotherapy, the average survival time of glioblastoma patients is less than 15 months (Liu et al. 2016). Additionally, approximately 70% of low-grade glioma patients develop to grade IV glioblastoma multiforme (GBM) within 5–10 years as ending (Furnari et al. 2007). With the development of molecular pathology in gliomas, several biomarkers routinely applied to evaluate gliomas include MGMT promoter methylation, EGFR alterations, IDH1 or IDH2 mutations, and 1p19q co-deletion and many of these markers have become standard of care for molecular testing and prerequisites for clinical trial enrollment(Rodriguez et al. 2016). Therefore, it's necessary to differentiate low-grade tumors to glioblastomas by understanding the molecular basis of different grades of glioma, which is an important step in defining new biomarkers and therapeutic strategies.

Gene expression profiling analysis is a useful method with broad clinical application for identifying tumor-related genes in various types of cancer, from molecular diagnosis to pathological classification, from therapeutic evaluation to prognosis prediction, and from drug sensitivity to neoplasm recurrence(De Preter et al. 2010; Freije et al. 2004; Kim et al. 2011; Kulasingam & Diamandis 2008). In recent years, large scales of gene profiling have been made to identify the overwhelming number of genes by the use of microarrays in clinical practice, and complicated and systemic statistical analyses should be made to provide both repeatability and

independent validation (Cheng et al. 2016).

In this analysis, GEO2R online tool was applied to look for the differentially expressed genes (DEGs) according to GSE52009 from Gene Expression Omnibus (GEO). Followed by, we produced a heatmap and picked out 15 genes with higher degree of connectivity from the DEGs selected. Furthermore, we analyzed cellular component (CC), biological process (BP), molecular function (MF) and KEGG pathways of the DEGs. In addition, the overall survival (OS) analysis and expression of these hub genes were made online. Then, we established PPI network of the DEGs and managed a GSEA using GBM patient gene profiling data (GSE53733).

2. Materials and Methods

2.1. Data of Microarray. Gene expression profile of GSE52009 and GSE53733 were downloaded from GEO database, which is a public and freely accessible database. Based on Agilent GPL6480 platform (Agilent-014850 Whole Human Genome Microarray 4x44K G4112F), GSE52009 dataset included 120 samples, containing 60 WHO II samples and 24 WHO IV samples. And GSE53733 was based on GPL570 platform ([HG-U133_Plus_2] Affymetrix Human Genome U133 Plus 2.0 Array), which contained 70 glioblastoma samples.

2.2. Screen Genes of Differential Expression. Differentially expressed genes between low grade glioma and high-grade glioma was detected by GEO2R, which was an online analysis tool based on R language (Davis & Meltzer 2007). We set the adjust P value < 0.05 and $|\log_{2}FC| \geq 2$ as the selection criteria to decrease the false positive rate and false discovery rate. Furthermore, the top 15 genes with higher degree of connectivity were selected as hub genes among the 133 discovered DEGs which includes 56 down-regulated genes and 77 up-regulated genes. In addition, we used visual hierarchical cluster analysis to show the two groups by Morpheus online analysis software (<https://software.broadinstitute.org/morpheus/>) and volcano plot of two groups by ImageGP (<http://www.ehbio.com/ImageGP/index.php/Home/Index/index.html>) after the relative raw data

of TXT files were downloaded.

2.3. Gene Ontology and KEGG Pathway Analysis of DEGs. With functions including molecular function, biological pathways, and cellular component, gene ontology (GO) analysis we annotated genes and gene products (2006). KEGG. comprises a set of genome and enzymatic approaches and abiological chemical energy online database (Kanehisa & Goto 2000). It is a resource for systematic analysis of gene function and related high-level genome functional information. DAVID (<https://david.ncifcrf.gov/>) can provide systematic and comprehensive biological function annotation information for high-throughput gene expression (Dennis et al. 2003). Therefore, we applied GO and KEGG pathway analyses to the DEGs by using DAVID online tools at functional level. We considered $P < 0.05$ had significant differences. In addition, we used visual analysis to show GO Enrichment plot of two groups by ImageGP (<http://www.ehbio.com/ImageGP/index.php/Home/Index/index.html>) after the relative raw data of TXT files were downloaded(Geng et al. 2018).

2.4. PPI network and module analysis. The online tool, Search Tool for the Retrieval of Interacting Genes (STRING), is designed to demonstrate the interaction between different proteins(Szklarczyk et al. 2015). STRING in Cytoscape was applied and mapped the DEGs into STRING to detect the possible relationship among the selected DEGs. We set the confidence score ≥ 0.4 , maximum number of interactors = 0 as the selection criteria. In addition, the Molecular Complex Detection (MCODE) was used to screen modules of PPI network in Cytoscape with degree cutoff = 2, node score cutoff = 0.2, k-core = 2, and max. depth = 100. DAVID was used to perform the signal pathway analysis of genes in the module. 15 hub genes were also mapped into STRING with confidence score ≥ 0.4 , maximum number of interactors ≤ 5 . The potential information was explored through GO and KEGG pathway analysis.

2.5. Comparing the expression level of the hub genes. The GlioVis (<http://gliovis.bioinfo.cnio.es/>)

is a user-friendly web application for data visualization and analysis to explore brain tumors expression datasets, which was used to analyze the gene expression data of brain tumors and normal samples based on the TCGA datasets. (Bowman et al. 2017). The customizable functions are provided such as analyzing the differences of expression levels between glioblastoma and low-grade glioma, so the expression of these genes was demonstrated. And the relationship could be visualized through the boxplot. All values are presented as the mean±SD. All statistical analyses were performed by SPSS 19.0 software. A difference of $P < 0.05$ was considered statistically significant.

2.6. Gene expression profile and gene set enrichment analysis. The expression profiles of GSE53733 was downloaded from the Gene Expression Omnibus (GEO). And we used gene set enrichment analysis (GSEA) (<http://www.broadinstitute.org/gsea>) to detect the potential genes influenced by SAA1 and TIMP1 through the Java programming. According to their hub genes expression level (top 50%: high vs bottom 50%: low), we divided the patients into two groups and GSEA was conducted to analyze the effects of selected genes expression level on different biological process. And we set P value of <0.05 and false discovery rates of <0.25 as selection criteria to confirm significant gene sets.

3. Results

3.1. Identification of DEGs and hub genes. 60 WHO II samples and 24 WHO IV samples from GSE52009 were selected in this study. DEGs were detected by applying the GEO2R online analysis tool, setting adjust P value < 0.05 and $|\log FC| \geq 2$ as selection criteria. 133 differential expressed genes, containing 77 up-regulated genes and 56 down-regulated genes, were detected after the analysis of GSE52009. In addition, we selected 15 hub genes with higher degree of connectivity (Table 1). The results were validated with a DEG expression heatmap and volcano plot of the all downregulated genes and upregulated genes (Figure 1).

3.2. GO function and KEGG pathway enrichment analysis. To explore more particular knowledge of the selected DEGs, we used DAVID to gain the results of GO function and KEGG pathway enrichment analysis. All DEGs were imported to DAVID software and GO analysis results demonstrated that up-regulated and down-regulated DEGs were particularly enriched in the following biological processes (BP): cell migration, locomotion and leukocyte migration, cell motility for up-regulated DEGs, and for downregulated DEGs nervous system development, brain development and regulation of cell projection organization (Table 2, Figure2a, Figure2b). The upregulated DEGs were enriched in phospholipase A2 inhibitor activity, growth factor binding, extracellular matrix structural construction, receptor binding, and the down-regulated DEGs were enriched in calcium ion binding, structural construction of myelin sheath, and protein complex binding for molecular function (MF) (Table 2, Figure2). Moreover, GO cell component (CC) analysis showed that the up-regulated DEGs were enriched in the proteinaceous extracellular matrix, extracellular matrix and cytoplasmic membrane-bounded vesicle lumen, and down-regulated DEGs enriched in neuron part, myelin sheath, and internode region of axon (Table 2, Figure2a, Figure2b).

Interestingly, the most significantly enriched of KEGG pathway only showed in up-regulated pathway, including adhesion, ECM-receptor interaction, amoebiasis and PI3K-Akt signaling pathway (Table3, Figure2c).

3.3. Hub Genes and Module Screening from PPI Network. PPI network of the top 15 hub genes with higher degree of connectivity was made based on the information in the STRING protein query from public databases (Figure 3A). The top module was selected by using MCODE plug-in in the PPI network. (Figure 3B).

3.4. The Kaplan-Meier Plotter of hub genes. The website, [http:// gepia.cancer-pku.cn/](http://gepia.cancer-pku.cn/), freely provides the prognostic data of the hub genes. It was found that expression of VEGFA (HR 4.2, p

= 0) was associated with worse overall survival (OS) for glioblastoma patients, as well as NDC80 (HR 5.8, $p = 0$), CENPA (HR 5.3, $p = 0$), CENPF (HR 3.9, $p = 0$), NCAPG (HR 5.6 $p = 0$), ASPM (HR 5, $p = 0$), ITGA2 (HR 3, $p = 0$), TIMP1 (HR 7, $p = 0$) and SAA1 (HR 4.8, $p = 0$). (Figure4).

3.5. Expression Level and relationship with molecular pathologic diagnosis of Hub genes. We used data from GlioVis to detect the hub gene expression level between glioblastoma and low-grade glioma including astrocytoma, oligodendroglioma and oligoastrocytoma reflect that compared to low-grade glioma, the expression level of SAA1 and TIMP1 significantly increased in glioblastomas (Figure 5A, 5C). And the expression level of SAA1 have no significant difference in three kinds LGG (Figure 5B). However, the expression level of TIMP1 is significantly higher in astrocytoma than oligodendroglioma and oligoastrocytoma (Figure 5D). We also detect the relationship between expression level and molecular pathologic diagnosis of hub genes. We found both SAA1 and TIMP1 increase in both IDH mutant IDH wild type. The same results were found in MGMT promoter and non-deletion of chromosome 1p.19q. Because of the limited samples in the datasets, we didn't the result of co-deletion of chromosome 1p.19q. (Figure 5E,5F) What's more, we also found that both SAA1 and TIMP1 played important roles in MES-like in the IDH wild type. (Figure 5G,5H)

3.6. Gene expression profile and gene set enrichment analysis. We managed a GSEA by using GBM patient gene profiling data (GSE53733), and showed in figure 5, gene set differences in SAA1 in low versus high glioma patients indicated that SAA1 regulates biology process mainly associated with inflammatory response processes ($P < 0.001$ FDR=0.012) and cytokine mediated signaling pathway ($P < 0.001$ FDR=0.012) (Figure5I, 5J). We considered that SAA1 may negatively regulate inflammatory response and might promote the survival of cancer cells. Seemingly we concluded that TIMP1 might negatively regulates adaptive immune response based on somatic recombination of immune receptors built from leucine-rich ($P < 0.001$ FDR=0.021) and response to interferon ($P < 0.001$ FDR=0.027) may promote the survival of cancer cells. (Figure5K,

189 5L)

190

191 4. Discussion

192

193 In this study, we identified 15 DEGs between glioblastoma and low-grade and used a series
194 of bioinformatics analyses to screen the key genes and pathways associated with glioma.
195 GSE52009 dataset contains 60 WHO II samples and 24 WHO IV samples. In order to improve the
196 statistical power of DEG, we defined that the absolute value of the logarithm (base 2) fold change
197 (logFC) greater than 2 and 133 DEGs were obtained. Bioinformatics analysis on DEGs, including
198 GO enrichment, KEGG pathway, PPI network, and survival analysis, expression level, gene set
199 enrichment analysis, found glioblastoma related genes and pathways that play important roles in
200 glioma development.

201 The GO analysis showed that the up-regulated DEGs were mainly associated with cell
202 migration, extracellular matrix structural construction, cell motility and down-regulated DEGs
203 were involved central nervous system development, calcium ion binding and internode region of
204 axon. Additionally, the KEGG pathways of up-regulated DEGs regulate focal adhesion, ECM-
205 receptor interaction, PI3K-Akt signaling pathway. Among these DEGs, we selected 15 hub genes
206 with higher degree of connectivity. In addition, we found several hub genes with worse overall
207 survival (OS) and higher expression level in glioma patients, including VEGFA, CXCL8, TIMP1,
208 SAA1, PLAT and NCAPG and we firstly found relationship of SAA1 ,TIMP1 and molecular
209 pathology in glioblastoma. We could hypothesize that these genes might contribute to the
210 malignance of glioma.

211 Serum amyloid A1 (SAA1) which was secreted by liver is an acute-phase high density lipo-
212 protein in immune response. Injury, inflammation, and brain trauma can elevate the plasma levels
213 of SAA1 (Lu et al. 2014; Villapol et al. 2015). What's more, it has long been suspected that SAA1
214 might be a prognostic marker and predictor of cancer risk. Elevated levels of SAA1 in the serum
215 of cancer patients directly correlate with poor prognosis and tumor aggressiveness in various types

of cancer, including lung cancer(Cho et al. 2010), cell renal carcinoma(Kosari et al. 2005), melanomas(Findeisen et al. 2009) and so on. Normal brain does not express SAA1(Liang et al. 1997), though an in vitro study demonstrated that microglia and astrocytes are responsive to SAA (Yu et al. 2014). Recently, it has been reported that SAA1 the expression levels in GBM patients are upregulated on both miRNA and protein in human glioblastoma, and SAA1 involves in angiogenesis via HIF-1 α and tumor associated macrophages(Knebel et al. 2017). Consistently, SAA1 has been reported as a molecular/metabolic signature that can help identify patients are at high risk of malignant GBM and promotes glioma cells migration and invasion through integrin α V β 3(Lin et al. 2018). What's more, although it's unknown why SAA1 upregulated in GBM and other malignant cancers, it has been speculated that SAA proteins play a primary role in the regulation of immunity and invasion processes (Moshkovskii 2012), which is consistent with the result of our study. Thus, we hypothesis SAA1 could be a biomarker of GBM and predict the prognosis of GBM patients. And the mechanism of SAA1 regulate in GBM need further research.

The tissue inhibitors of metalloproteinases (TIMPs, including TIMP-1, TIMP-2, TIMP-3, TIMP-4) are well known play critical roles in both metastasis and invasion through extracellular matrix remodeling which are controlled by the activity of matrix metalloproteinases (MMPs) (Jackson et al. 2017; Ries 2014). Among the four well-known TIMPs characterized so far, most focus has been on TIMP-1 defined as a naturally occurring inhibitor of most MMPs, a family of zinc dependent endopeptidases essential for degrading components of the ECM(Aaberg-Jessen et al. 2009). In addition, TIMP1 shows protease-independent function including anti-apoptotic, antiangiogenic, and differentiation activities in cells (Bridoux et al. 2013; Mandel et al. 2017). Over the past year, more and more studies focus on the influence of TIMP1 in cancers. Serum or urine levels of TIMP1 are also considered as a diagnostic predictor in pancreatic ductal carcinomas containing extensive desmoplasia(Jenkinson et al. 2015; Roy et al. 2014). Increased levels of cytosolic TIMP1 in pretreatment tumor tissue is associated with a significantly shorter overall survival in patients with breast cancer receiving standard adjuvant chemotherapy(Dechaphunkul et al. 2012). And it has been reported that low expression of TIMP-1 in glioblastoma patient

predicts longer survival. The shorter survival of glioblastoma patients with a high tumor TIMP-1 level may be explained by the antiapoptotic effect of TIMP-1 preventing apoptosis induced by radiation and chemotherapy(Aaberg-Jessen et al. 2009). More recently, Aaberg-Jessen C et al demonstrated that Co-expression of TIMP-1 and CD63 might have effects in glioblastoma stemness and may predict the poor prognosis of patients through influencing tumor aggressiveness and resistance of therapy(Aaberg-Jessen et al. 2018). We consider TIMP-1 can be identified as a future biomarker for prognosis or monitoring patients' treatment response. However, all these studies didn't demonstrate the specific mechanism, which is the direction for further researches.

5.conclusion,

We presumed these key genes identified by a series of bioinformatics analyses on DEGs between glioblastoma samples and low-grade glioma samples, probably related to the development of glioma. These hub genes could also affect the survival time of glioma patients. These identified genes and pathways provide a more detailed molecular mechanism for underlying glioma initiation and development. According to the study, SAA1 and TIMP1 can be considered as biomarkers or therapeutic targets or monitoring patients' treatment response for glioblastoma. However, further molecular and biological experiments are required to confirm the functions of the key genes in glioblastoma.

Figure 1(on next page)

Differentially expressed gene expression heat map and volcano plot of glioma.

Figure 1 : (A) Differentially expressed gene expression heat map of glioma (all upregulated and downregulated genes). (B) Differentially expressed genes were selected by volcano plot filtering (fold change ≥ 1 and p value ≤ 0.05). The blue point in the plot represents the differentially expressed genes with statistical significance.

Figure 2 (on next page)

GO analysis results showed that upregulated DEGs

Figure 2 : GO analysis results showed that upregulated DEGs (A) and downregulated DEGs (B) were particularly enriched in BP, MF, and CC. (C) The most significantly enriched KEGG pathway of the upregulated DEGs. GO: gene ontology; BP: biological process; MF: molecular function; CC: cell component; KEGG: Kyoto Encyclopedia of Genes and Genomes.

Figure 2

Figure 3 (on next page)

protein-protein interaction network and top module of hub genes

Figure 3 : (A) The protein-protein interaction network of top 15 hub genes. (B) Top module from the protein-protein interaction network.

Figure 4(on next page)

Prognostic value of hub genes (VEGFA, NDC80, CENPA, CENPF, NCAPG, ASPM, ITGA2, TIMP1, and SAA1) in glioma patients.

Figure 4 : Prognostic value of hub genes (VEGFA, NDC80, CENPA, CENPF, NCAPG, ASPM, ITGA2, TIMP1, and SAA1) in glioma patients. HR: hazard ratio.

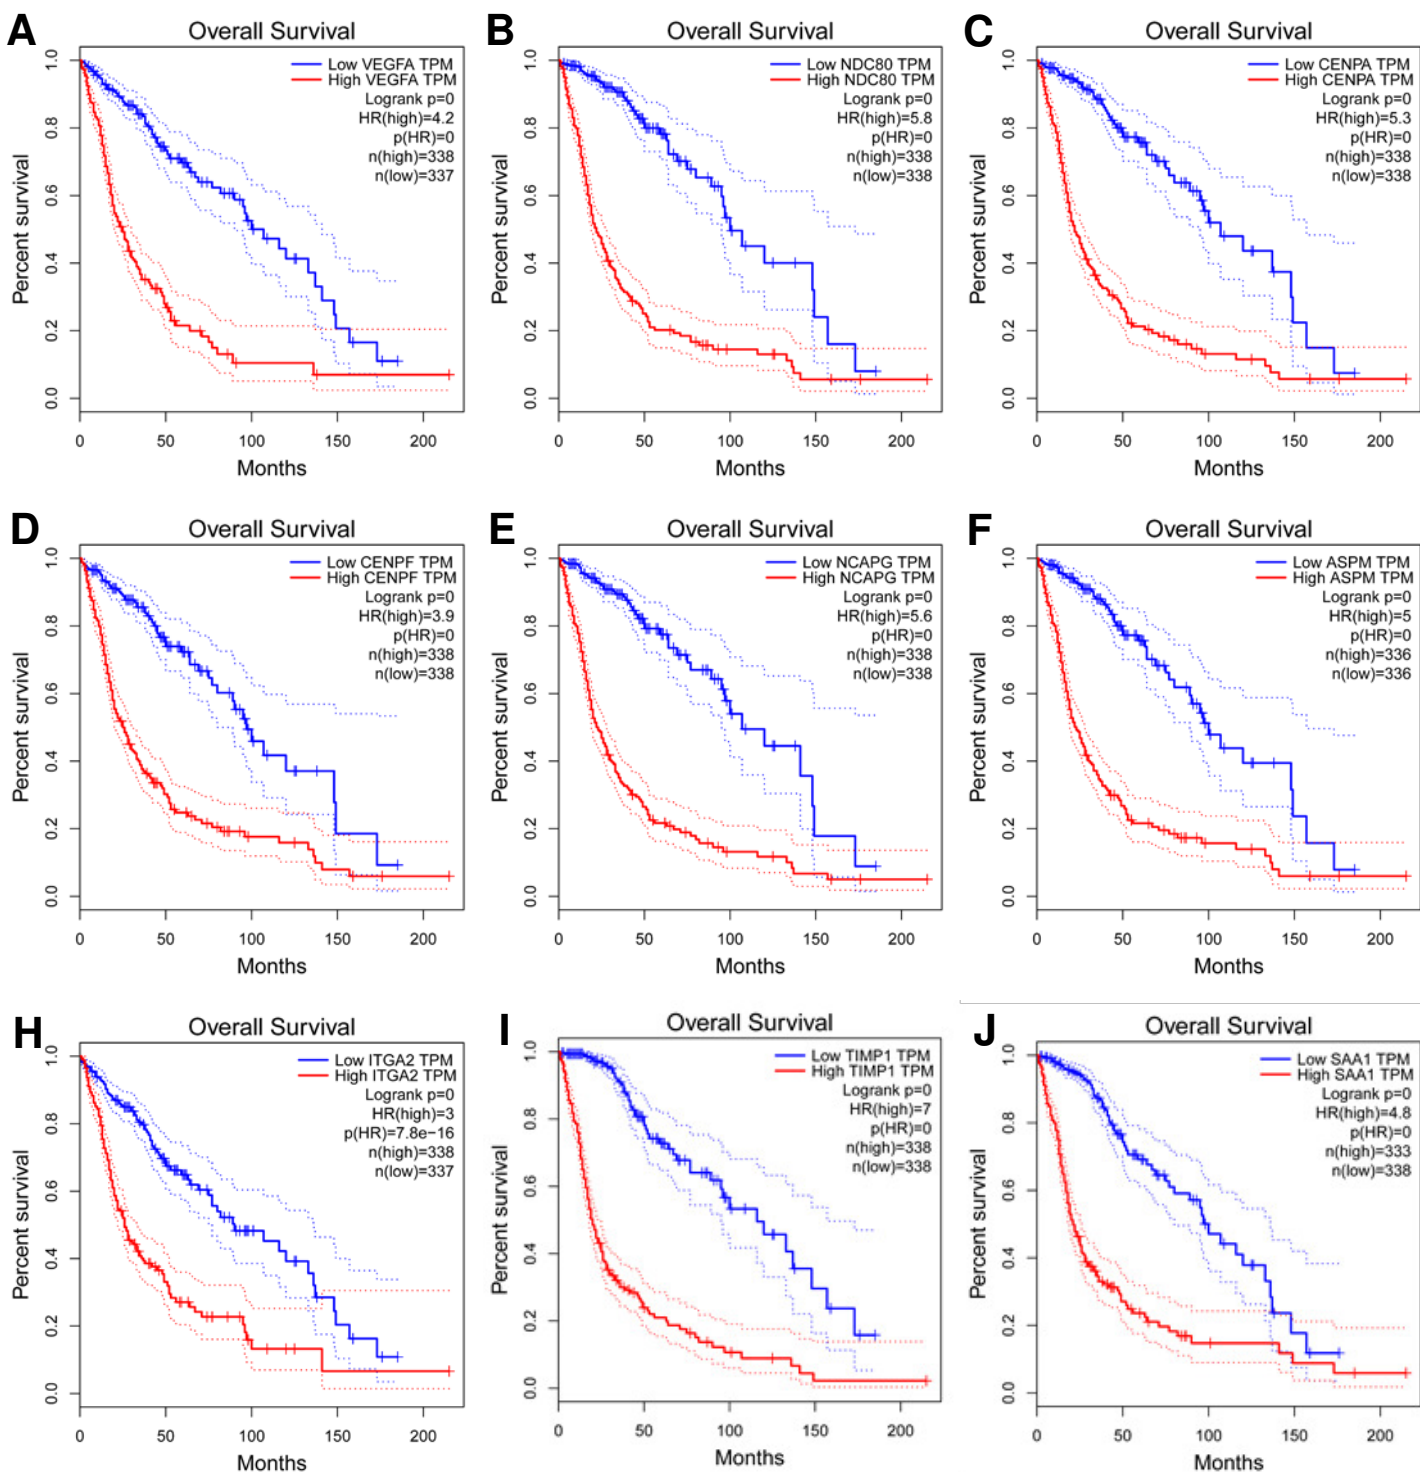

Figure 5(on next page)

the expression level and potential function of SAA1 and TIMP1

Figure 5 : (A) SAA1 significantly increased in glioblastomas; (B) The expression level of SAA1 have no significant difference in LGG; (C) TIMP1 significantly increased in glioblastomas; (D) TIMP1 is significantly higher in astrocytoma than oligodendroglioma and oligoastrocytoma; (E, F) SAA1 and TIMP1 increase in both IDH mutant IDH wild type. The same results were found in MGMT promoter and non-deletion of chromosome 1p.19q; G, H. SAA1 and TIMP1 played important roles in MES-like in the IDH wild type; (I, J) SAA1 regulates biology process associated with inflammatory response processes and cytokine mediated signaling pathway; (K, L). TIMP1 negatively regulates adaptive immune response based on somatic recombination of immune receptors built from leucine-rich and response to interferons.
