Abstract

Crowdsourcing shifts medical research from a closed environment to an open collaboration between the public and researchers. We define crowdsourcing as an approach to problem solving which involves an organization having a large group attempt to solve a problem or part of a problem, then sharing solutions. Crowdsourcing allows large groups of individuals to participate in medical research through innovation challenges, hackathons, and related activities. The purpose of this literature review is to examine the definition, concepts, and applications of crowdsourcing in medicine. This multi-disciplinary review defines crowdsourcing for medicine, identifies conceptual antecedents (collective intelligence and open source models), and explores implications of the approach. Several critiques of crowdsourcing are also examined. Although several crowdsourcing definitions exist, there are two essential elements: (1) having a large group of individuals, including those with skills and those without skills, propose potential solutions; (2) sharing solutions through implementation or open access materials. The public can be a central force in contributing to formative, pre-clinical, and clinical research. A growing evidence base suggests that crowdsourcing in medicine can result in high-quality outcomes, broad community engagement, and more open science.

48 **Introduction**

49 Crowdsourcing is an approach to problem solving that has gained momentum in the past

50 decade.(Han et al. 2018; Pan et al. 2017) Crowdsourcing involves an organization having a large

51 group attempt to solve a problem or a component of a problem, then sharing solutions.(van Ess

52 2010) This concept has facilitated ways for the public to engage in medical research, including

53 innovation challenges (also called prize competitions, prize contests, or open contests),

54 hackathons, online systems for collaboration, and other activities (Table 1).(Brabham et al. 2014;

55 Pan et al. 2017; Ranard et al. 2014) We define medicine as the science and practice of

56 preventing, diagnosing, and treating human disease.(2019) Crowdsourcing is related to open

57 innovation, diverging from conventional closed innovation medical research in several ways

58 (Table 2).(Chesbrough 2003)

59

60 Systematic reviews(Crequit et al. 2018; Ranard et al. 2014) and a World Health Organization

61 practical guide on crowdsourcing(Han et al. 2018) demonstrate a growing evidence base

62 supporting crowdsourcing in medicine. Some crowdsourcing projects have asked groups to

63 develop health communication materials (e.g., images, videos) to promote HIV, hepatitis, and

64 STI testing.(Tang et al. 2018; Zhang et al. 2017b; Zhang et al. 2015) Others have used

65 crowdsourcing to accelerate antibiotic and other drug development.(Desselle et al. 2017;

66 Grammer et al. 2016; Shaw 2017; Tuffery 2015) However, this literature has not examined

67 broader concepts and applications related to crowdsourcing in medicine.

68

69   The diversity of crowdsourcing approaches complicates attempts to achieve a single overarching

70   conceptual framework.(Ringh et al. 2015; Tang et al. 2016a) Some have suggested that

71   crowdsourcing lacks a strong conceptual foundation.(Geiger et al. 2011a) Others argue that the

72   relatively brief history of crowdsourcing makes it premature to consider conceptual or theoretical

73   elements.(Geiger et al. 2011b) However, the conceptual basis of crowdsourcing reaches well

74   beyond the first use of the term. This history alongside more recent data on collective

75   intelligence and open-source models pave the way for a better understanding of crowdsourcing

76   concepts and applications.

77

78   **Review Methodology**

79   This literature review examined the peer-reviewed and gray literature on crowdsourcing

80   approaches related to medicine. We searched PubMed, Google Scholar, ResearchGate, and

81   Academia.edu to identify potential studies for inclusion on February 25th 2019. We focused on

82   manuscripts that defined conceptual issues and applications of crowdsourcing for medical

83   research. We excluded studies that were not in English. This manuscript defines crowdsourcing

84   for medicine, identifies conceptual antecedents, considers relationships with other approaches,

85   and examines common critiques.

86

87   **Crowdsourcing: A Definition**

88   There have been many definitions of crowdsourcing since Jeff Howe coined the term in

89   2005.(Brabham 2008; Howe 2006; Ranard et al. 2014; Tang et al. 2018; Wazny 2017) The term

90   is a portmanteau composed of "crowd" and "outsourcing." The original definition was applied to

91   describe companies outsourcing tasks to a group of individuals who worked collectively or

92   individually. Howe himself realized that this initial definition was overly narrow and later

93   expanded it to include the application of open-source principles to fields outside of software.

94   However, this definition and many of the existing ones(Brabham 2008; Ranard et al. 2014) do

95   not include the subsequent obligation to share solutions. Henk van Ess suggested that

96   crowdsourcing involves those with skills and those without skills attempting to solve a problem,

97   then freely sharing some solutions with the public.(van Ess 2010) We have included the sharing

98   component for the following reasons: crowdsourcing activities draw on the strength of many

99   laypeople who will not receive incentive prizes (e.g., gifts, money, mentorship, or other

100   benefits); there are ethical problems with leveraging group insights (either individually or

101   collectively) and not giving back to the group(Tucker et al. 2018); not sharing would likely

102   diminish enthusiasm for sustained engagement from those who contribute to challenges; sharing

103   may be more likely to advance medical knowledge. Many individuals who participate in

104   crowdsourcing activities report altruistic motivations, hoping to help their community or the

105   public at large.(2018b; Mathews et al. 2018; Zhang et al. 2017b) Including a sharing component

106   fulfills this obligation to give back to the public.

107

108   First, an organization has a group (including those with skills and those without skills) attempt to

109   solve a problem. The group could be working independently or collaborating as a team. The

110   rationale for sourcing solutions from a group rather than select individuals includes the

111   following: (1) the potential for groups to have relevant knowledge and experiences in a related

112   field; (2) the importance of public participation and community consultation in health services;

113   (3) the potential for local end-users, patients, and others to be more actively engaged in the

114   process of developing new ideas; (4) the inclusion of people from the community to assist in

115   designing interventions that would be feasible and relevant in the local community. The group

116   participation component of crowdsourcing has been used by states, international organizations,

117   and non-profits for centuries. For example, in 1714, the British government wanted to find an

118   accurate method to measure a ship's longitudinal position. They offered a cash prize to

119   whomever developed a solution that met pre-specified benchmarks. This spurred many groups to

120   focus on enhanced methods for measuring longitude, resulting in important advances in this

121   field.(2009)

122

123   The second key component of crowdsourcing involves sharing solutions. This could be

124   accomplished through implementing the solution in a local community(Tang et al. 2018) or

125   creating open access materials for public use.(Wu et al. 2018) For example, the rights to an

126   exceptional crowdsourced image could be made widely available through creative commons

127   attribution. Crowdsourcing approaches may generate a range of materials and products that can

128   be shared in both digital and in-person formats. Some examples of ways that crowdsourced

129   materials have been shared include: providing crowdsourced images, concepts, and logos to the

130   public through an open access website;(Wu et al. 2018) widely distributing images through

131   social media;(Zhang et al. 2015) evaluating the effectiveness of the crowdsourced output through

132   a trial;(Tang et al. 2016a; Tang et al. 2016c; Tang et al. 2018) holding a series of in-person

133   workshops to communicate crowdsourced findings with key stakeholders.(Zhang et al. 2017a)

134

135 These two crowdsourcing components – group participation and sharing solutions – are each

136 indebted to earlier multidisciplinary concepts on collective intelligence and open source models,

137 respectively. The next two section explores these related concepts as they inform crowdsourcing.

138

139 **Collective Intelligence**

140 Collective intelligence suggests that in certain settings, a group is better able to solve difficult

141 problems than an individual working alone. The concept is not a universal statement about

142 groups being wiser than individuals, but rather that there are certain contexts wherein this is true.

143 The collective intelligence concept has a history in political science, philosophy, social science,

144 and biology. Perhaps the earliest mention of this concept was in 1785 when Marquis de

145 Condorcet published a theorem about the relative probability of a given group of individuals

146 arriving at a correct decision.(de Condorcet 1785) The theorem examines the optimal number of

147 voters when engaging in a group decision. The number is greater when there is a higher

148 probability of each voter making a correct decision; the number is small when there is a lower

149 probably of each voter making a correct decision. This provides a theoretical basis for

150 democracy and has been widely used in political science.(Austen-Smith & Banks 1996; Ladha

151 1992) Within a health context, Condorcet's theorem has been used in clinical diagnostic

152 imaging(Gottlieb & Hussain 2015) and reviewing organ transplant eligibility.(Koch & Ridgley

153 2000)

154

155 Philosophers and others have contributed to the development of a collective intelligence concept.

156 The French philosopher Pierre Lévy defined collective intelligence as "a form of universally

157   distributed intelligence, constantly enhanced, coordinated in real time, and resulting in effective

158   mobilization of skills."(Lévy 1997) Social reformers have also used collective intelligence as a

159   key guiding principle. H. G. Wells described a "World Brain" concept that would help citizens to

160   share information as a group,(Wells 1938) benefiting from local knowledge and experience

161   within a common platform. He envisioned the platform as a non-commercial resource that would

162   span political boundaries and help expand knowledge.(Wells 1938) The crowdsourced

163   encyclopedia, Wikipedia, echoes some of the structures and functions of Wells' original world

164   brain concept.

165

166   Empirical evidence from humans suggests that in some contexts, a convergent collective

167   intelligence factor explains a group's performance on several tasks.(Woolley et al. 2010) Further

168   empirical evidence supporting collective intelligence is summarized in James Surowiecki's *The*

169   *Wisdom of Crowds*.(Surowiecki 2004) He argues that four elements are necessary for collective

170   intelligence – diversity of opinion, independence of individual ideas, decentralization of ideas,

171   and a way to aggregate individual ideas. Surowiecki shows how collective intelligence has been

172   used in many different contexts, ranging from prediction markets to the Delphi method. The

173   Delphi method has a group of individuals iteratively answer questions and converge on a single

174   answer. The method has been widely used to achieve group consensus in health

175   guidelines.(Diamond et al. 2014)

176

177   Collective intelligence approaches have been evaluated in several medical settings. Research

178   among medical students suggests that groups of medical students have increased diagnostic

179 performance compared to individual medical students.(Hautz et al. 2015; Kammer et al. 2017)

180 Similar approaches have been evaluated in the context of physician diagnosis of skin

181 cancer(Kurvers et al. 2016) and breast cancer.(Wolf et al. 2015)

182

183 **Open Source Model**

184 Open source models can inform the second important component of crowdsourcing – sharing

185 solutions. Open source refers to a decentralized structure that facilitates collaboration and online

186 sharing. Open source models were developed in the 1960s and 1970s as a way to collaboratively

187 develop software and share code.(von Hippel & von Krogh 2003) In 1969, the United States

188 Advanced Research Project Agency created the first large, high-speed computer network. This

189 extended opportunities for sharing code among broader online groups. For example, the Linux

190 operating system is one of the first open source operating systems, shared online and available

191 for free to anyone. Linus Torvalds developed the source code for this operating system by

192 sending it to other internet users who helped improve it on a volunteer basis. The collective

193 development of open source products, such as Linux, demonstrate how large, diverse groups

194 working together can iteratively enhance a product that is openly available, to the benefit of all.

195

196 This trend also led to the development of Creative Commons, a non-profit organization that

197 allows individuals to legally change and share creative works. The organization has a series of

198 copyright licenses that clarify the terms of sharing. There are currently approximately 1.4 billion

199 works that have been licensed through Creative Commons.

200

201   Open source models have increasingly appeared in medicine. For example, several drug

202   development projects have used open source models.(Bombelles & Coaker 2015; Munos 2006;

203   Munos 2010; So et al. 2011) A project called Open Source Pharma focuses on developing drugs

204   through open source methods. Thousands of volunteers from over 100 countries have helped

205   with micro-tasks to develop more effective drugs for tuberculosis, schistosomiasis, and other

206   infectious diseases.(Bhardwaj et al. 2011) The open source platform has resulted in high-quality

207   research, including advances related to the development of schistosomiasis drugs.(Ardal &

208   Rottingen 2012) Other open source models for drug discovery have been developed for

209   Huntington's disease,(Wilhelm 2017) malaria,(Ardal & Rottingen 2015) eumycetoma,(Lim et al.

210   2018) and other diseases.(Bagla 2012)

211

212   Open source models have also been used within genomics. A Shiga-toxin producing *E. coli*

213   outbreak occurred in Germany in 2011, infecting 3000 individuals. Scientists used an open

214   source model to organize the analysis of a genome sequence from a single individual. The

215   collaborative effort brought together volunteers from around the world, creating the genome

216   sequence within two weeks of receiving the DNA samples.(Rohde et al. 2011) In addition, the

217   DREAMS Challenge team has organized many open source innovation challenges.(Saez-

218   Rodriguez et al. 2016) These typically involve volunteers collaboratively working together to

219   solve a problem related to big data and genomics. Several evaluations of this approach have

220   found it to be effective in developing prognostic models based on clinical data.(Allen et al. 2016;

221   Guinney et al. 2017; Noren et al. 2016) Both collective intelligence and open source models

222   reveal some of the theoretical antecedents of crowdsourcing.

223

224 **Relationship to Other Research Approaches**

225 Crowdsourcing as an approach is distinct from, but related to community-based participatory

226 research, participatory action research, and community-driven research. Each of these different

227 approaches has a conceptual framework, methods, and assumptions. At the same time, each of

228 these three approaches can be used to inform medical research.

229

230 Community-based participatory research actively engages the community in all stages of the

231 research process, contributing to shared decision making and community ownership.(Minkler &

232 Wallerstein 2003) The community plays a central force in setting the agenda, implementing the

233 study, and evaluating the results, such that local community members and researchers iteratively

234 collaborate to improve the health of the community. Similarities between community-based

235 participatory research and crowdsourcing include the following: a focus on listening to and

236 partnering with local communities; a potential to increase healthy equity; an acknowledgement

237 that communities can be a powerful source of new ideas. These areas of convergence suggest

238 that community-based participatory research could be a useful complement to crowdsourcing.

239 For example, community-based participatory research was used to increase community

240 engagement in an HIV cure research project.(Mathews et al. 2018)

241

242 Other related approaches include participatory action research and youth participatory action

243 research. Participatory action research focuses on partnering with communities to participate in

244 research and achieve social change.(Bradbury 2015) Youth participatory action research

245 provides youth with opportunities to learn about social problems that affect their lives and then

246   propose actions to address these problems.(Cammarota & Fine 2008; Cammarota & Fine 2010;

247   Kirshner 2010; Ozer et al. 2016) The participatory action approach considers youth as potential

248   experts and co-creators of knowledge.(Ozer 2016) Shared elements of crowdsourcing and

249   participatory research approaches include the emphasis on participation, local community

250   partnerships, and empowerment of the public. Participatory action research has been used to

251   complement crowdsourcing projects related to environmental health(English et al. 2018) and to

252   design crowdsourcing approaches for HIV self-testing.(2018c)

253

254   Finally, community-driven research is another approach related to crowdsourcing. Community-

255   driven research has community members and researchers collaboratively design, implement,

256   analyze, interpret, and disseminate research findings.(Orionzi et al. 2016) Community-driven

257   research starts with an assessment of local priorities from the perspective of the community.

258   Both community-driven research and crowdsourcing focus on community-led research,

259   developing ideas and programs from the bottom-up for the community.(McElfish et al. 2015)

260   All three of these approaches have been used in health research. We now turn to examine

261   crowdsourcing specifically in the context of health.

262

263   **Critiques of Crowdsourcing**

264   There are three main critiques of crowdsourcing that merit consideration – the madness of groups

265   concept, the problem of low-quality submissions, and cognitive fixation on examples. We will

266   examine each of these critiques generally and then in the context of crowdsourcing as it applies

267   to medicine.

268

269   First, the madness of groups refers to the potential for groups to create and disseminate popular

270   delusions, contributing to panic and moral outrage.(Mackay 1852) The nineteenth century

271   journalist Charles Mackay remarked, "Men, it has been said, think in herds; it will be seen that

272   they go mad in herds, while they only recover their senses slowly, and one by one."

273   Psychologists have examined how individual behaviors contribute to and diverge from the

274   collective behavior of the groups. Group behavior may be associated with a loss of

275   responsibility. This is illustrated in the case of Boaty McBoatface, a boat name chosen from a

276   public online poll in the United Kingdom. This name was the most popular in the

277   #NameOurShip poll, but ultimately not used to name the ship.(Ellis-Petersen 2016) One example

278   of mad crowds in the context of medicine is low vaccine uptake. Several negative social media

279   reports that spread through online networks have influenced vaccine uptake and disease

280   outbreaks.(Larson et al. 2013)

281

282   However, crowdsourcing as an approach does not suggest that all groups are wise at all times,

283   but rather that there are specific conditions that can allow for wise groups. In addition, several

284   individuals have made rebuttals and clarified the concept of a mad group. Clark McPhail has

285   shown how mad groups are primarily the result of individuals, rather than a group

286   disposition.(McPhail 1991) Empirical data on whether group behavior results in a loss of

287   responsibility has been mixed.(Manstead & Hewstone 1995) Within the context of medicine,

288   online platforms have propagated myths and misunderstandings about disease.(Lavorgna et al.

289   2017; Powell et al. 2016) Submissions to innovation challenges may include myths,(Mathews et

290   al. 2018) but judging typically finds these submissions of lower quality. Other ways to limit the

291   risk of mad crowds is to have multi-phase challenges with vetting(Fitzpatrick et al. 2018) or

292   online moderation of submission platforms.(Rice et al. 2016)

293

294   Second, crowdsourcing projects are sometimes associated with many low-quality outputs. A

295   systematic review of crowdsourcing suggests that only a subset of outputs are excellent.(Pan et

296   al. 2017) Having those without formal training contribute to a more complex medical project will

297   result in a wide range of outputs, especially when mass engagement translates into hundreds of

298   submissions. However, the ability to prompt a large number of submissions is an advantage of

299   crowdsourcing and suggests that a wider group of individuals is actively participating. Several

300   techniques for judging have been developed to assess large numbers of crowdsourcing

301   contributions,(Han et al. 2018) including group judging (having a group of individuals

302   evaluate),(Tang et al. 2018) panel judging (having a diverse group of individuals

303   evaluate),(Zhang et al. 2015) and artificial intelligence.(Albarqouni et al. 2016; Mudie et al.

304   2017) Several systematic reviews of crowdsourcing in medicine suggest that crowdsourcing

305   allows a broad range of quality, including both low and high-quality submissions.(Crequit et al.

306   2018; Dai et al. 2017; Ranard et al. 2014)

307

308   Finally, the problem of cognitive fixation on prior ideas has been described in crowdsourcing.(Fu

309   et al. 2017) This refers to the phenomenon when providing an example or reference limits the

310   diversity of ideas solicited. This concept is similar to groupthink, which occurs when a group of

311   individuals converges on a single solution.(Janis 1972) There are several technical ways of

312   designing a crowdsourcing project that could limit cognitive fixation, including the following:

313   limiting the use of examples when calling for innovative ideas; drawing on different groups of

314   individuals or different topics (avoiding serial challenges focused on the same topic); and having

315   a submission system in which those who submit do not view other submissions.

316

317   **Crowdsourcing Applications in Medical Research**

318   Crowdsourcing approaches have already been used to enhance formative, pre-clinical, and

319   clinical research (Table 3). Crowdsourcing approaches have been used to assist in the discovery

320   and development of antibiotics,(Desselle et al. 2017) lupus drugs,(Grammer et al. 2016) and anti-

321   malarials.(Spangenberg et al. 2013) Several crowdsourcing activities have been used to prepare

322   for clinical and other medical research. Crowdsourcing approaches have identified potentially

323   relevant citations as part of systematic reviews. This approach has been found

324   reliable(Mortensen et al. 2017) and is being piloted as part of a Cochrane program.(2018a)

325

326   Crowdsourcing could accelerate several stages of drug development, including screening, pre-

327   clinical trials, and human clinical trials. Screening of potential drug candidates has been opened

328   to the public through crowdsourcing activities in several fields. The Medicines for Malaria

329   Venture(Spangenberg et al. 2013) and a tuberculosis consortium(Ballell et al. 2013) both used

330   crowdsourcing to catalyze drug target identification. At the pre-clinical stage of drug

331   development, sharing of chemical probes with the public has created a new class of

332   bromodomain inhibitors.(Arshad et al. 2016; Scott 2016) Within human trials, several studies

333   have used crowdsourcing to develop human clinical trial study messaging and community

334   engagement.(Leiter et al. 2014; Mathews et al. 2017; Pan et al. 2017) Many studies have used

335   Amazon Turk or other platforms to recruit study participants into online randomized controlled

336   trials.(Jones et al. 2013; Losina et al. 2017; Tang et al. 2016a; Tang et al. 2016b) While such

337   approaches are often rapid and save money, there are concerns about generalizability.(Wang et

338   al. 2017)

339

340   **Conclusion**

341   Our observations about using crowdsourcing in medical research have several important

342   limitations. First, we did not focus our analysis based on different categories of crowdsourcing

343   because other systematic reviews have covered this territory.(Crequit et al. 2018; Wang et al.

344   2018) Second, although there is a growing literature on crowdsourcing in medical research,(Pan

345   et al. 2017) the number of randomized controlled trials and related studies is still limited.(Wang

346   et al. 2018) Third, we have not included a list of areas which problems may be more amenable to

347   crowdsourcing because this has been partially covered in a previous review(Wazny 2017) and is

348   difficult to infer from the existing literature.

349

350   This review suggests several important areas for future crowdsourcing research in medicine.

351   More rigorous research studies are needed to expand our understanding of crowdsourcing,

352   including studies with comparator groups (e.g., randomized controlled trials), cost-effectiveness

353   research, and qualitative studies. In addition, given that much of the crowdsourcing medical

354   research to date has benefitted from academic medical schools as innovation hubs,(Siefert et al.

355   2018) further development of crowdsourcing in medical training and education may be

356   warranted. The design of innovation challenges is widely known among practitioners to

357   influence the ultimate success of crowdsourcing activities, but these design elements are not

358   frequently captured in studies. Further methodological innovation and research are needed.

Crowdsourcing activities used to improve medical research: structure and function.

Crowdsourcing activities in medical research include innovation challenges, hackathons, and online collaboration systems.

Table 1. Crowdsourcing activities used to improve medical research: structure and function

Crowdsourcing activity	Structure	Function
Innovation challenges	Open solicitation and promotion to the public for challenge submissions; evaluation, celebration, and sharing of challenge submissions	Generate innovative ideas, logos, images, or videos (e.g., images to increase HIV testing, strategies to promote hepatitis testing); accelerate pharmaceutical drug development
Hackathons	Short (often 3 days) event that brings together individuals around a common cause	Design a clinical algorithm, prevention service (e.g., design an HIV testing service), or new technology
Online collaboration systems	Websites or portals that allow individuals to solve a problem	Solve micro-tasks for a small amount of money (e.g., evaluation of surgical skills)

Comparison of conventional medical research and crowdsourced approaches.

Most medical research uses a framework of closed innovation (middle column).

Crowdsourcing proposes an open innovation approach (right column).

2   **Table 2. Comparison of conventional medical research and crowdsourced approaches.**

	Conventional medical research (closed innovation)	**Crowdsourced approach (open innovation)**
Medical research questions	Those with medical research skills know best how to frame questions.	A diverse group of individuals together know best how to frame questions.
Methods for innovation	Internal teams led by experts, with little input from outside	Collaborative co-creation with non-experts and the public engaged
Intellectual property	Focus on controlling IP so that competitors will not benefit	Use others' IP when it advances the research

Crowdsourcing applications in medical research.

Crowdsourcing can be used to inform formative work, pre-clinical research, and clinical research.

Table 3. Crowdsourcing applications in medical research.

Crowdsourcing Application	Purpose of Crowdsourcing	Examples
Informing medical research (formative)	Optimize search processes	Assist with systematic reviews
Pre-clinical research	Share key elements necessary for drug development	Curate data on drugs; Accelerate genomic analysis
Clinical and translational research	Recruiting study participants; community engagement	Solicit community feedback; enhance drug development
