**Background:** Maize (*Zea mays* L.) is a principal cereal crop cultivated worldwide for human food, animal feed, and more recently as a source of biofuel. However, as a direct consequence of water insufficiency and climate change, frequent occurrences of both biotic and abiotic stresses have been reported in various regions around the world, and recently, this has become a constant threat in increasing global maize yields. Plants respond to abiotic stresses by utilizing the activities of transcription factors, which are families of genes coding for specific transcription factor proteins. Transcription factor target genes form a regulon that is involved in the repression/activation of genes associated with abiotic stress responses. Therefore, it is of uttermost importance to have a systematic study on each transcription factor family, the downstream target genes they regulate, and the specific transcription factor genes involved in multiple abiotic stress responses in maize and other staple crops.

**Method:** In this review, the main transcription factor families, the specific transcription factor genes and their regulons that are involved in abiotic stress regulation will be briefly discussed. Great emphasis will be given on maize abiotic stress improvement throughout this review, although other examples from different plants like rice, Arabidopsis, wheat, and barley will be used.

**Results:** We have described in detail the main transcription factor families in maize that take part in abiotic stress responses together with their regulons. Furthermore, we have also briefly described the utilization of high-efficiency technologies in the study and characterization of TFs involved in the abiotic stress regulatory networks in plants with an emphasis on increasing maize production. Examples of these technologies include next-generation sequencing, microarray analysis, machine learning and RNA-Seq.

**Conclusion:** In conclusion, it is expected that all the information provided in this review will in time contribute to the use of TF genes in the research, breeding, and development of new abiotic stress tolerant maize cultivars.

31 **Abstract**

32 **Background:** Maize (*Zea mays* L.) is a principal cereal crop cultivated worldwide for human  
33 food, animal feed, and more recently as a source of biofuel. However, as a direct consequence of  
34 water insufficiency and climate change, frequent occurrences of both biotic and abiotic stresses  
35 have been reported in various regions around the world, and recently, this has become a constant  
36 threat in increasing global maize yields. Plants respond to abiotic stresses by utilizing the  
37 activities of transcription factors, which are families of genes coding for specific transcription  
38 factor proteins. Transcription factor target genes form a regulon that is involved in the  
39 repression/activation of genes associated with abiotic stress responses. Therefore, it is of  
40 uttermost importance to have a systematic study on each transcription factor family, the  
41 downstream target genes they regulate, and the specific transcription factor genes involved in  
42 multiple abiotic stress responses in maize and other staple crops.

43 **Method:** In this review, the main transcription factor families, the specific transcription factor  
44 genes and their regulons that are involved in abiotic stress regulation will be briefly discussed.  
45 Great emphasis will be given on maize abiotic stress improvement throughout this review,  
46 although other examples from different plants like rice, Arabidopsis, wheat, and barley will be  
47 used.

48 **Results:** We have described in detail the main transcription factor families in maize that take  
49 part in abiotic stress responses together with their regulons. Furthermore, we have also briefly  
50 described the utilization of high-efficiency technologies in the study and characterization of TFs  
51 involved in the abiotic stress regulatory networks in plants with an emphasis on increasing maize  
52 production. Examples of these technologies include next-generation sequencing, microarray  
53 analysis, machine learning and RNA-Seq.

54 **Conclusion:** In conclusion, it is expected that all the information provided in this review will in  
55 time contribute to the use of TF genes in the research, breeding, and development of new abiotic  
56 stress tolerant maize cultivars.

## 67 Introduction

68 Abiotic stresses for instance drought, salinity, cold, high temperatures and mineral toxicity are  
69 the main cause of major crop yield reductions worldwide, reducing expected average yields of  
70 the major crops by more than 50% (Prasad et al., 2011; Mahalingam, 2015). Plants are sessile  
71 beings that are continuously exposed to various changes in the environmental conditions.  
72 Variations in the environment involving both biotic and abiotic stresses have negative effects on  
73 economically important crops like maize (Ramegowda and Senthil-Kumar, 2015). Evolutionary  
74 changes have helped many plants adapt to different adverse conditions. Some species show a  
75 marked increase in tolerance to various abiotic stresses compared to others (Phukan et al., 2014).  
76 Due to global warming and the climatic abnormalities accompanying it, the frequencies of  
77 combined biotic and abiotic stresses have significantly increased, leading to reduced growth and  
78 yield of the major crops worldwide (Mittler., 2006; Pandey et al., 2015; Ramegowda and Senthil-  
79 Kumar, 2015). Moreover, continuous manifestations of abiotic stresses such as heat and drought  
80 together, has led to severe reductions in crop yields as opposed to when these stresses occur  
81 separately during the different growth stages (Mittler., 2006; Prasad et al., 2011).

82 Maize (*Zea mays* ssp. *Mays* L) is one of the most important cereal crops cultivated worldwide  
83 (particularly in Africa and South America). Global maize production increased from 255 million  
84 tonnes in 1968 to 1,134 million tonnes in 2017 representing an average annual growth of 3.46%.

85 ([https://knoema.com/atlas/World/topics/Agriculture/Crops-Production-Quantity-tonnes/Maize-](https://knoema.com/atlas/World/topics/Agriculture/Crops-Production-Quantity-tonnes/Maize-production)  
86 [production](https://knoema.com/atlas/World/topics/Agriculture/Crops-Production-Quantity-tonnes/Maize-production)). Maize production has significantly enlarged in both the developing countries and  
87 the developed countries (Wang et al., 2013).

88 Maize is a staple food in many parts of the world; it is consumed directly by humans, used for  
89 animal feed, and in other maize products such as corn syrup and corn starch. In the last century,  
90 maize has been utilized as a model system in the study of various biological events and systems  
91 including paramutation, transposition, allelic diversity, and heterosis (Bennetzen and Hake.,  
92 2009). Recently, maize has been identified as a potential sustainable feedstock, as well as a  
93 model system for research in the bioenergy and biofuel industries (Perlack et al., 2005).  
94 Continuous study in maize genetics has led to further understanding of other related C4 grasses  
95 such as Elephant grass (*Miscanthus giganteus*) and switchgrass (*Panicum virgatum*) as scientists  
96 aim to develop and domesticate these plants (Perlack et al., 2005). However, maize belts around  
97 the world which range from the latitude 40° South to the latitude 58° North are exposed to  
98 continuous effects of both biotic and abiotic stresses (Gong et al., 2014). Abiotic stresses, like  
99 salinity, drought, nutrient deficiency, and high and low temperatures are the major environmental  
100 factors that negatively influence maize production. In particular, intense waterlogging, extreme  
101 temperatures, and drought have significantly affected maize yields (Ahuja et al., 2010).

102 Plants must cope with a variety of abiotic stresses including extreme temperatures, heavy metals,  
103 osmotic stresses, and high light intensity. Under stress, accumulation of some metabolites  
104 positively regulates plants response to both abiotic and biotic stresses thus protecting plants from  
105 multiple stresses (Rasmussen et al., 2013). Changes in ions fluxes, callose accumulation,  
106 phytohormones, and ROS are the first responses induced to tackle the stresses, leading to  
107 metabolic reprogramming in the plants defenses (Bartoli et al., 2013).

108 Reactive oxygen species such as hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) and superoxide (•O<sub>2</sub><sup>-</sup>) which are  
109 produced due to oxidative stresses, inhibit photosynthesis and cause vast cellular destruction

110 (Allan and Fluhr, 2007). ROS are normally removed rapidly by antioxidative mechanisms,  
111 although this removal can be hindered by the stresses leading to an increase in ROS  
112 concentration inside the cells, and further increasing the damage caused (Allan and Fluhr, 2007).

113 Another pathway involved in abiotic stress responses in plants is the Mitogen-Activated Protein  
114 Kinase (MAPK) cascades. MAPK cascades are activated following the recognition and  
115 perception of stress stimuli and control the stress response pathways (Wurzinger et al., 2011).  
116 They are highly conserved in eukaryotes and are responsible for signal transduction in various  
117 cellular processes under different biotic and abiotic stress responses. Because MAPKs are  
118 involved in various stress responses, they play a main role in the combination of biotic and  
119 abiotic stresses (Amajová et al., 2013).

120 Additionally, hormone signaling in plants is another important pathway involved in biotic and  
121 abiotic stress responses and the primary hormone involved is ABA. An increase in ABA  
122 concentration in plants under abiotic stress modulates the abiotic stress-regulation network  
123 (Xiong et al., 2002), while biotic stress is mediated by antagonism in other stress hormones such  
124 as JA/ET and SA (Liu et al., 2008). The role of ABA in abiotic stress responses has been widely  
125 described throughout this review.

126 Plants do not respond to multiple stresses by way of a linear pathway. The responses are  
127 complex circuits involving various pathways in tissues, cellular specific compartments and the  
128 interactions of signaling molecules in controlling a particular response to a stimulus  
129 (Dombrowski, 2003). Due to abiotic stresses, numerous proteins and gene transcripts are altered  
130 through the regulation of protein turnover and gene expression (Jiang et al., 2007; Wong et al.,  
131 2006).

132 In this review, we will briefly describe the main TF families and the interactions of these TFs  
133 with the *cis*-acting elements (CREs) which are present in the promoter regions of stress  
134 responsive genes. Even though TF regulons have been described recently by (Gahlaut et al 2016;  
135 Joshi et al., 2016), this review will focus on TFs involved in abiotic stress tolerance with a  
136 specific focus on maize. We will also focus on new ways of increasing production of maize by  
137 utilizing currently available genomic information, tools and data.

138

### 139 **Survey methodology**

140 All published manuscripts cited in this review were obtained from different databases including  
141 Pubmed, Web of Science, EBSCO, Google Scholar, research gate, Science Direct, SCOPUS,  
142 JSTOR, SciELO, and Semantic Scholar. Key words such as “maize stress tolerance”,  
143 “transcription factors involved in abiotic stress responses”, “abiotic stress”, “transcription factor  
144 downstream genes”, and “regulons involved in abiotic stress” were searched between 10 January  
145 to 25 October 2018. We have critically analyzed articles to provide an in-depth and  
146 comprehensive research trend focusing on the TFs involved in abiotic stress tolerance in maize.  
147 Furthermore, we have provided perspectives on the latest research as well as previous findings  
148 with focus on TF families involved in abiotic stress responses in maize.

149

150

151

## 152 **Functions of Transcription Factors**

153 Abiotic stress-induced genes are generally classified into two main groups based on their protein  
154 products. One type includes the genes coding for products which directly allow cells to resist  
155 environmental stresses for instance osmotic regulatory protein, late embryogenesis abundant  
156 (LEA) protein, enzymes synthesizing proline, betamine, malondialdehyde (MDA) and other  
157 osmotic regulators and anti-freezing proteins (Loredana et al., 2011). The second type of genes  
158 are regulatory proteins which operate in the signal transduction networks, for example, molecular  
159 chaperones, functional proteins, and transcription factors (TFs) or kinases (Song et al., 2013;  
160 Loredana et al., 2011).

161 Networks of transcription factors together with transcription factor binding sites (TFBS) directly  
162 control transcriptional regulation of plant genes (Chaves and Oliveira, 2004). Transcription  
163 factors are proteins usually consisting of two domains, namely (1) the DNA binding domain  
164 (DB) and (2) an activation domain (AD). A TF binds to the *cis*-acting element (TF binding site)  
165 located in the promoter region of a stress-induced gene with the support of a DB domain  
166 (Yamasaki et al., 2013). This event brings the AD close to the target gene leading to repression  
167 or activation of this gene. A large percentage of genes in the plant genome (nearly 10%)  
168 essentially encode for transcription factors (Franco-Zorrilla et al., 2014). TFs activate or repress  
169 the activity of RNA polymerase, leading to gene regulation. TFs can be categorized into various  
170 families based on their DNA binding domains (Riechmann et al., 2000). Since abiotic stresses  
171 are quantitative traits that might require regulation of several genes including the TF genes, and  
172 since a single transcription factor may regulate several genes that are involved in abiotic stress  
173 tolerance. A detailed study of all TFs associated with abiotic stress regulatory mechanisms in  
174 maize will be significantly rewarding. For example, Xu et al. (2006) successfully converted flood  
175 sensitive rice genotypes into flood-tolerant varieties by introgression of the *sub1* locus which  
176 encodes an (ethylene response factor) TF, leading to the induction of about 900 stress-responsive  
177 genes.

178 TF DNA-binding domains are strongly conserved between species, to the extent of using these  
179 characteristics to classify the TFs into various families (Fig. 1). These families differ among  
180 plant species in that different plant systems have between 26 to 83 TFs families (Jin et al., 2014).  
181 In *Arabidopsis*, for instance, approximately 34 families consisting of 1533 TFs have so far been  
182 classified (Riechmann et al., 2000). Additionally, in *Arabidopsis* and many other plants,  
183 transcriptome data revealed a number of pathways which respond to abiotic stresses  
184 independently, pointing to the possibility that susceptibility or tolerance of both biotic and  
185 abiotic stresses are controlled by a sophisticated gene regulatory network at the transcriptome  
186 level (Umezawa et al., 2006).

187 Abscisic acid (ABA) is the principal hormone involved in the coordination of abiotic stress in  
188 plants (Fig. 1). This hormone regulates a complex gene regulatory system that enables plants to  
189 handle decreased moisture availability (Cutler et al., 2010). ABA-dependent gene activation  
190 pathways were identified as pathways which determine stress tolerance by the induction of at  
191 least two separate regulons: the first one is the myeloblastosis oncogene (MYB)/  
192 myelocytomatosis oncogene (MYC) regulon and the second one, is the ABA-responsive element  
193 binding protein/ ABA-binding factor (AREB/ ABF) (Abe et al., 1997; Saibo et al., 2009) (Fig.

194 1). ABA- independent regulons include; the NAC (CUC, NAM and ATAF) and the zinc-finger  
195 homeodomain (ZF-HD) regulon (Nakashima et al., 2009; Saibo et al., 2009) (Fig. 1).

196 The different stress tolerance responsive TFs normally function independently, although there is  
197 a possibility that some level of cross-link occurs between these TFs (Fig. 2). Many studies have  
198 shown that ABA-independent and ABA-dependent pathways might converge at several  
199 unexpected points. This points of convergence represent transcriptional repressors and enhancers  
200 interacting indirectly or directly with DRE/C repeat and ABRE and hence initiate synergistic  
201 interactions between ABA response and osmotic stress (Fig. 2).

202 The above mentioned TF families have been studied in detail in a number of important food  
203 crops and also in model plant systems including; *Arabidopsis thaliana*, *Oryza sativa*, *Triticum*  
204 *aestivum*, *Sorghum bicolor*, *Vitis vinifera*, *Hordeum vulgare*, *Solanum tuberosum*, and *Brassica*  
205 *napus*. Recent studies have shown the functions of abiotic stress-responsive TFs, and their  
206 potential roles to be used in future for purposes of molecular breeding and improvement of  
207 different crop varieties.

208 Much progress has been achieved in our understanding of transcriptional regulation, signal  
209 transduction, and gene expression in plant responses to abiotic stresses (Zhu et al., 2010). In rice  
210 for example, overexpression of a NAC TF encoding gene, *SNAC1* resulted in increased yields  
211 and increased tolerance to drought in transgenic plants (Hu et al., 2006). Overexpression of a  
212 *Glycine soja* NAC TF designated as *GsNAC019* in transgenic *Arabidopsis* resulted in plants that  
213 were tolerant to alkaline stress at both the seedling and mature stages although the transgenic  
214 plants had reduced sensitivity to Abscisic acid (ABA) (Cao et al., 2017). Similarly, functional  
215 analysis of a *Pyrus betulifolia* NAC TF gene designated as *PbeNAC1*, revealed that this gene is  
216 involved in the regulation of cold and drought stress tolerance (Jin et al., 2017). Additionally, a  
217 chickpea (*Cicer arietinum*) stress associated TF, *CarNAC4* was linked with reduced MDA  
218 content and water stress rates in response to salinity and drought stress respectively (Yu et al.,  
219 2016).

220 Ramakrishna et al. (2018) showed that overexpression of a finger millet bZIP TF gene *EcbZIP17*  
221 in tobacco plants resulted in higher germination rate, increased biomass, and increased survival  
222 rate in the transgenic plants. Furthermore, the transgenic tobacco plants also showed increased  
223 seed yields compared to the control plants. Likewise, Xu et al. (2016) showed that transgenic  
224 *Arabidopsis* and soybean seedlings overexpressing a soybean bZIP TF designated as  
225 *GmbZIP110* had improved salt tolerance, suggesting that *GmbZIP110* functions as a positive  
226 regulator involved in salt stress tolerance. Functional analysis of *GmbZIP110* in transgenic  
227 *Arabidopsis* revealed that this gene could bind to the ACGT motif and regulate many  
228 downstream target genes (Cao et al., 2017). Elsewhere, overexpression of an *Arabidopsis* bZIP  
229 TF designated as *ABF3* in transgenic alfalfa (*Medicago sativa*) under the command of a sweet  
230 potato oxidative stress-inducible promoter *SWPA2*, resulted in improved growth under drought  
231 stress (Wang et al., 2016c). In hot pepper (*Capsicum annuum*), overexpression of a bZIP  
232 encoding gene *CaBZI* in transgenic potato significantly improved dehydration stress tolerance  
233 without any detrimental effects on plant growth or yield (Moon et al., 2015).

234 Overexpression of *OsMYB55*, a rice MYB encoding gene in transgenic maize resulted in  
235 improved plant growth as well as decreased negative effects of drought and high temperature  
236 (Casaretto et al., 2016). Wei et al. (2017) demonstrated that *CiMYB3* and *CiMYB5* cloned from  
237 *Cichorium intybus* were both involved in the fructan pathway degradation in response to various

238 abiotic stresses. In banana (*Musa paradisiaca*), overexpression of an MYB TF gene designated  
239 as *MpMYBS3* significantly improved tolerance to cold stress in transgenic plants (Dou et al.,  
240 2015). Elsewhere, a MYB TF gene designated as *MtMYBS* from *Medicago truncatula* was able to  
241 enhance salt and drought tolerance in transgenic *Arabidopsis* by improving the primary root  
242 growth (Dong et al., 2017). Likewise, overexpression of *GaMYB62L* from cotton (*Gossypium*  
243 *arboreum*) in transgenic *Arabidopsis* resulted in enhanced drought tolerance (Butt et al., 2017).

244 The exogenous expression of *AtDREB1A* (Dehydration responsive element binding proteins)  
245 gene from *Arabidopsis* in transgenic *Salvia miltiorrhiza* resulted in plants with higher antioxidant  
246 activities and photosynthetic rates under drought stress (Wei et al., 2016). Elsewhere,  
247 overexpression of *SbDREB2A* from *Salicornia brachita* in transgenic tobacco resulted in  
248 improved growth and seed germination under hyperionic and hyperosmotic stresses (Gupta et al.,  
249 2014). Zhang et al. (2015) cloned SsDREB protein from *Suaeda salsa* and showed that this  
250 protein enhances the photosynthesis rate in transgenic tobacco plants under drought and salt  
251 stresses.

252 In the WYKY TF gene family, *OsWRKY71* from rice was found to act as a positive regulator to  
253 cold stress tolerance by regulating several downstream genes like *WSI76* and *OstGFR* (Kim et  
254 al., 2016). VIGS (Virus-induced gene silencing) of *GhWRKY6* gene from cotton (*Gossypium*  
255 *hirsutum*) led to increased sensitivity to various abiotic stresses in the silenced plants (Ullah et  
256 al., 2017). Elsewhere, *SIDRW1* and *SLWRKY39* which are WRKY TFs were found to confer  
257 both abiotic and biotic stress tolerance in tomato (*Solanum lycopersicum*) by activating both  
258 abiotic stress and pathogenesis-related downstream genes (Liu et al., 2014a; Sun et al., 2015).

259 TFs and regulons involved in abiotic stress regulation from other TF families have also been  
260 identified and described. For instance in *Populus euphratica*, exogenous expression of *PeHLH35*  
261 belonging to the bHLH TF family resulted in significant improvement in water deficit tolerance  
262 through changes in several physiological processes such as stomatal density and transcription  
263 rate (Dong et al., 2014). In tomato, overexpression of a cycling Dof factor (CDF) TF designated  
264 as *CDF3* resulted in increased biomass production and higher yields in transgenic tomato plants  
265 under salt stress (Renau-Morata et al., 2017).

266

## 267 **TFs and the specific target genes involved in abiotic stress tolerance in maize**

268

### 269 **MYC/ MYB regulon**

270 The MYC (myelocytomatosis)/ MYB (myeloblastosis) families of TF proteins have diverse  
271 functions and are found in both animals and plants (Abe et al., 2003). Both MYB/ MYC TFs  
272 participate in the ABA-dependent pathway involved in abiotic stress signaling (Fig. 1). The first  
273 MYB TF gene in plants was identified in Maize and was designated as *CI*, it codes for a c-MYB  
274 like TF that is involved in the biosynthesis of anthocyanin (Paz-Ares et al., 1987). In the MYB  
275 family, each TF consists of an MYB domain containing 1 to 3 imperfect repeats and is made up  
276 of around 52 amino acid residues with a helix-turn-helix (HTH) conformation which interposes  
277 inside the major grooves of DNA (Yanhui et al., 2006). Both MYB and MYC TFs are usually  
278 involved in making up the common regulons known as the MYB/ MYC regulons (Gahlaut et al.,  
279 2016).

280 In the maize genome, Du et al. (2013) reported 72 MYB related proteins. Chen et al. (2017)  
281 analyzed the expression profiles of 46 MYB genes from maize, in response to various abiotic  
282 stresses and found 22 genes that responded to the different stress conditions. Additionally, 16 of  
283 these genes were induced in response to a minimum of two stresses. These results suggesting that  
284 these genes could take part in signal transduction pathways involved in abiotic stress responses.  
285 Additionally, the function of *ZmMYB30* which was significantly up-regulated under drought,  
286 salt, and ABA stresses was further analyzed (Table. 1). Exogenous expression of *ZmMYB30* in  
287 *Arabidopsis* stimulated tolerance to salt and elevated the expression of eight abiotic stress  
288 corresponding genes (*ABF3*, *ATGols2*, *AB15*, *DREB2A*, *RD20*, *RD29B*, *RD29A*, and *MYB2*)  
289 enabling transgenic plants to be more tolerant to adverse environmental conditions (Table. 1).  
290 Moreover, another six genes (*RD22*, *RbohD*, *P5CS1*, *RAB18*, *RbohF*, and *LEA14*) were either  
291 unchanged or slightly elevated in the transgenic *Arabidopsis* plants.

292 Another maize MYB TF, *ZmMYB31* was found to repress the biosynthesis of sinopoylmalate  
293 leading to increased sensitivity to UV irradiation and dwarfism in transgenic plants (Fornale et  
294 al., 2010). Furthermore, *ZmMYB31* activated a number of stress-responsive genes (*ZmF5H*, *C3H*,  
295 *ZmActin* and *ZmCOMT*) in vivo in maize, and *4CL1* and *COMT* genes in transgenic *Arabidopsis*.  
296 The roles of maize MYB related genes in response to drought stress were examined based on  
297 microarray data (Dash et al., 2012; Du et al., 2013). On the maize 18k GeneChip, 26 probe sets  
298 were shown to correspond to 32 MYB-related genes (whereby five probes represented one gene).  
299 Further analysis of this highly similar sequence data revealed that the majority of the MYB-  
300 related genes were expressed at low levels, although their expression was in response to a  
301 specific stress. Elsewhere, gene expression analysis between two maize varieties, a drought  
302 sensitive (Ye478) variety, and a drought tolerant (Han21) variety was found to be very similar  
303 (Du et al., 2013). For instance, four CCA1-like/ R-R genes (*ZmMYBR49*, *ZmMYBR19*,  
304 *ZmMYBR56*, and *ZmMYBR28*), six TBP-like genes (*ZmMYBR55*, *ZmMYBR45*, *ZmMYBR47*,  
305 *ZmMYBR31*, *ZmMYBR26*, and *ZmMYBR07*) and a single TRF-like gene (*ZmMYBR41*) were all  
306 elevated in response to drought stress. Expression analysis of *ZmMYBR37* an I-box-like gene,  
307 and five CCA1-like/ R-R genes (*ZmMYBR63*, *ZmMYBR44*, *ZmMYBR27*, *ZmMYBR18*, and  
308 *ZmMYBR03*), showed that these genes were highly down-regulated in response to drought stress.  
309 Although recovery of all these genes above was observed after re-watering (Table. 1). Similarly,  
310 a maize R1-type TF that is encoded by *ZmMYB-R1* gene was activated by cold, exogenous ABA,  
311 drought, heat and high salinity (Liu et al. 2012). Functional analysis of *ZmMYB-R1* in different  
312 tissues revealed it first reached its maximum levels in the leaves and later it was detected in the  
313 roots and stems.

314 In the model plant *Arabidopsis*, MYB and MYC TFs were found to accumulate in plant tissues  
315 following the accumulation of ABA (Lata et al., 2007). Seven *Arabidopsis* MYB TF genes  
316 namely *AtMYBCDC5*, *AtMYB77*, *AtMYB73*, *AtMYB44*, *AtMYB6*, *AtMYB7*, and *AtMYB4* were all  
317 strongly expressed in all organs, in response to several abiotic stresses (Yanhui et al., 2006).  
318 Functional analysis of two MYB/ MYC genes, (*AtMYC2* and *AtMYB2*) in transgenic *Arabidopsis*  
319 revealed that the TF proteins encoded by these two genes can bind to the promoter regions of  
320 several ABA or jasmonic-acid (JA) inducible genes. For example, *AtADH1* and *RD22* thus  
321 making the transgenic *Arabidopsis* plants ABA-responsive and more tolerant to both drought and  
322 osmotic stress (Abe et al., 2003).

323 Taken together, all the above findings suggest that *MYB* genes could be engineered in crops  
324 leading to activation of general pathways involved in abiotic stress responses in plants. For

325 instance, overexpression of *OsMYB55*, a rice R2R3-MYB TF significantly improved rice plants  
326 tolerance to extreme temperatures, and this was directly linked with improved amino acid  
327 metabolism (El-kereamy et al., 2012). Additionally, these findings will facilitate our  
328 understanding of gene regulation by MYB TFs, thus leading to the development of new abiotic  
329 stress tolerant crop varieties. Finally, Phylogenetic, functional and structural analyses revealed  
330 that most homologous MYB proteins that possess conserved domains have similar activities and  
331 functions in divergent plant species. Although a lot of information is available on the molecular  
332 functioning of MYB TFs in abiotic stress responses, deciphering the downstream and upstream  
333 events in MYB TFs in abiotic stress responses remains an immense undertaking.

334

### 335 **The AP2/EREBP regulons**

336 The AP2/EREBP (ethylene-responsive element binding protein) family is made up of a large  
337 group of plant specific TFs that are characterized by the presence of a highly conserved  
338 AP2/ethylene-responsive element binding factor (ERF). The ERF interacts directly with GCC  
339 box and/or DRE/C-repeat element (CRT) at the promoter site of downstream target genes  
340 (Reichmann and Meyerowitz, 1998). AP2/EREBP TFs play vital roles in stress responses and  
341 developmental processes such as cell proliferation, plant hormone responses, and biotic and  
342 abiotic stress responses (Sharoni et al., 2011). Based on the similarity and number of AP2/ERF  
343 domains, AP2/EREBP TFs are grouped into four main subfamilies: ERF, RAV (related to  
344 AB13/VP1), DREB and AP2 (Apetala 2) (Sharoni et al., 2011). Among these four, the DREB  
345 subfamily has been extensively studied due to the roles its TFs play in plant biotic and abiotic  
346 stress responses.

347 Dehydration responsive element binding proteins (DREBs) play a significant role in the ABA-  
348 independent pathways that are responsible for the activation of abiotic stress-regulatory genes  
349 (Lata et al., 2007). DREB TFs are made up of one AP2/ERF DNA binding region, which binds  
350 to the *cis*-acting element DRE composed of TACGACAT (a 9bp core sequence) and is present in  
351 the promoters of Abiotic stress-responsive genes (Gahlaut et al., 2016). The existence of this *cis*-  
352 acting element (CRE) has been recorded in several abiotic stress-responsive genes for example  
353 *RD29B* and *RD29A* in *Arabidopsis* (Yamaguchi-Shinozaki and Shinozaki, 1994). C-repeat  
354 (CRT) *cis*- acting elements consisting of the A/GCCGAC motif and which are similar to DREBs,  
355 have been identified in the promoter regions of cold-responsive genes in *Arabidopsis*, whereby  
356 the CRT elements bind to the TF CBF (CRT binding factor) in response to cold stress (Saleh et  
357 al., 2005). In *Arabidopsis* for example, exogenous overexpression of *AtDREB1/CBF* led to cold,  
358 drought, and high salinity tolerance in transgenic plants. These findings clearly suggest that  
359 DREBs/CBFs TFs have the potential to target multiple stress-responsive candidate genes in the  
360 plant genomes (Jaglo-Ottosen et al., 1998; Kasuga et al., 1999).

361 In maize, the role of DREB TFs has been investigated by adopting both molecular and genetic  
362 analyses. For example, *ZmDREB1A* was activated by cold stress and moderately elevated by  
363 high-salinity stress in maize seedlings (Qin et al., 2004) (Table. 1). Over-expression of  
364 *ZmDREB1A* in transgenic *Arabidopsis* led to induced over-expression of abiotic stress-activated  
365 genes giving rise to plants with enhanced tolerance to extreme drought and freezing stresses  
366 (Table. 2). Investigations were done to ascertain whether *ZmDREB1A* could induce other genes  
367 in the dehydration and/or cold pathways of wild-type plants. The results revealed that expression  
368 levels of *KIN1*, *KIN2*, and *COR15A* were all highly up-regulated in the 35S:*ZmDREB1Aa*

369 transgenic line under normal conditions when compared to the wild-type plants. Expression  
370 analysis of *RD17*, *ERD10* and *RD29A* showed that these genes were slightly up-regulated in the  
371 35S:*ZmDREB1Aa* transgenic line. The above results showed that *ZmDREB1A* induces both  
372 ABA-independent genes like (*COR15A*, *KIN1*, and *KIN2*) and ABA-dependent genes like  
373 (*RD17*, *ERD10*, and *RD29A*). Therefore, it was concluded that this gene might affect the  
374 expression of dehydration and cold-responsive genes in both the ABA-independent and ABA-  
375 dependent pathways. Likewise, another DREB TF gene *ZmDBP3* was highly induced by cold  
376 and moderately induced by salinity stress (Wang and Dong, 2009) (Table. 1). Over-expression of  
377 this gene in transgenic *Arabidopsis* led to improved tolerance to both cold and drought stresses  
378 (Table. 2).

379 Natural variations present in the promoter region of another maize DREB TF gene *ZmDREB2*,  
380 lead to drought tolerance in maize (Liu et al., 2013) (Table. 1). In transgenic *Arabidopsis*, over-  
381 expression of *ZmDREB2* resulted in plants with enhanced tolerance to drought. Elsewhere, qRT-  
382 PCR analysis of maize leaves revealed that expression of *ZmDREB2A* was induced by  
383 dehydration, heat and cold stress (Qin et al., 2007). Overexpression of *ZmDREB2A* in transgenic  
384 *Arabidopsis* resulted in dwarf plants with enhanced tolerance to drought and heat stresses.  
385 Microarray analysis of these transgenic *Arabidopsis* plants identified a number of genes  
386 associated with detoxification and heat shock for example *RD29B* and *At5G03720*. Moreover,  
387 five genes coding for late embryogenesis abundant (LEA) proteins (*LEA14*, *At1g52690*,  
388 *At3G53040*, *At3G15670*, and *At2G36640*) in addition to a metabolism associated gene *AtGoIS3*,  
389 were all up-regulated under different stress treatments in the transgenic lines (Table. 1).  
390 Elsewhere, functional analysis of *ZmDBF3* showed that this TF gene was activated by drought,  
391 high temperature, salt, cold and abscisic acid (ABA). However, no significant difference was  
392 noted under methyl jasmonate (MeJA) and salicylic acid (SA) (Zhou et al., 2016). Ectopic  
393 expression of *ZmDBF3* in yeast (*Saccharomyces cerevisiae*) resulted in a higher survival rate  
394 during exposure to KCl, Na<sub>2</sub>CO<sub>3</sub>, NaHCO<sub>3</sub>, NaCl, PEG 6000, sorbitol, and freezing  
395 temperatures. Moreover, exogenous expression of *ZmDBF3* in transgenic *Arabidopsis*  
396 considerably improved tolerance to drought, freezing and salt stresses (Table. 2). These findings,  
397 suggest that *ZmDBF3*, a novel maize DREB TF may have similar functions to a regulatory factor  
398 taking part in abiotic stress response pathways. Similarly, overexpression of *ZmDBP4* in  
399 *Arabidopsis* resulted in transgenic plants with improved cold and drought stress tolerance (Wang  
400 et al., 2011) (Table. 2). Analysis of the promoter region of *ZmDBP4* identified *cis*-acting  
401 elements which responded to abiotic stresses, suggesting that *ZmDBP4* encodes a functional  
402 factor that plays an important role in the control of multiple abiotic stress responses in maize.  
403 Elsewhere, mRNA accumulation analysis profiles of two DRE-binding proteins (*DBF1* and  
404 *DBF2*) in maize seedlings revealed that *DBF1* was induced during embryogenesis and in  
405 response to drought, ABA, and NaCl treatments (Kizis and Investigacio, 2002).

406 DREB TFs are versatile when it comes to abiotic stress regulation. Recently, numerous studies  
407 have been done to understand the roles DREB TFs play in abiotic stress responses and to reveal  
408 the mechanisms involved in their transcription and post transcriptional regulation. Collectively,  
409 these studies suggest that DREB TFs can be potential candidates for abiotic stress tolerance,  
410 although these studies have not addressed the vital question of whether DREB TFs can improve  
411 the yield of engineered crops under stress. Many DREB homologues have been identified and  
412 isolated from different plant species, especially from plant species with exceptional tolerance to  
413 different abiotic stresses. Thus, the focus now is to evaluate the existing methods of yield

414 analyses under different stress conditions and to assess transgenic plants in actual field  
415 conditions.

416

### 417 **NAC TFs and regulons**

418 The TF members in the NAC family, (ATAF, CUC, and NAM) represent one of the largest  
419 plant-specific TFs (Ooka et al., 2003). In the main crop species, a large number of NAC TFs  
420 have been analyzed and sequenced at the genome-wide level. These include 151 members in rice  
421 and 117 in *Arabidopsis* (Nuruzzaman et al., 2010), 204 members in the Chinese cabbage (Liu  
422 T.K et al., 2014b) and 152 members in maize (Shiriga et al., 2014). The TFs belonging to the  
423 NAC family share a greatly conserved N-terminus made up of 150-160 amino acid residues,  
424 constituting a DNA-binding domain that carries five sub-domains (A-E) and a varying C-  
425 terminal (Hu et al., 2008; Ooka et al., 2003). The NAC genes and their constituent *cis*-acting  
426 elements (NACRs) make up the NAC regulons, which further provide vital examples of finely  
427 characterized collaboration between a single TF and one or more *cis*-acting elements that  
428 associate in response to multiple stresses (Christianson et al., 2010). The roles of NAC TFs in  
429 plants have been extensively studied in rice and *Arabidopsis*. In *Arabidopsis* for example, an  
430 *ERD1* (early dehydration stress 1) gene was activated by a number of NAC TFs including  
431 *ANAC055*, *ANAC019*, and *ANAC072* (Tran et al., 2007). A rice NAC TF designated as OsNAM,  
432 was found to regulate the activation of five genes (*OsAH*, *OsCESA*, *OsMtN3*, *OsGdpD*, and  
433 *OsGDP*) in response to drought (Dixit et al., 2015). Several NAC TFs utilize the NACRS motif  
434 in plants, for instance *SNAC2* and *ENAC1* found in rice (Sun et al., 2012) and *ANAC055*,  
435 *ANAC072* and *ANAC019* found in *Arabidopsis* (Tran et al., 2004).

436 In maize, several NAC TFs involved in abiotic stress regulatory pathways have been isolated,  
437 cloned and characterized. Recently, expression analysis of *ZmSNAC1* in maize seedlings  
438 revealed that this TF gene was strongly induced by high salinity, drought, ABA treatment, and  
439 low temperature, although it was down-regulated in response to salicylic acid (SA) treatment (Lu  
440 et al., 2012). Over-expression of *ZmSNAC1* in transgenic *Arabidopsis* led to increased  
441 hypersensitivity to osmotic stress and ABA as well as enhanced tolerance to dehydration stress at  
442 the germination phase (Table. 2). These results suggest that *ZmSNAC1* acts as a multiple stress  
443 responsive TF, positively modulating abiotic stress tolerance in maize. Elsewhere, Shiriga et al.  
444 (2014) identified 11 NAC TF genes in maize that were induced by various abiotic stresses. This  
445 prediction was confirmed when these genes were differentially expressed in response to drought  
446 stress. Four genes, *ZmNAC45*, *ZmNAC72*, *ZmNAC18*, and *ZmNAC51* were all up regulated in the  
447 drought-tolerant maize genotypes and down-regulated in the drought susceptible genotypes.  
448 Recently, seven ZmNTL, NAC TFs genes (*ZmNTL1*, *ZmNTL2*, *ZmNTL3*, *ZmNTL4*, *ZmNTL5*,  
449 *ZmNTL6*, and *ZmNTL7*) were analyzed in maize seedlings and all seven genes were found to be  
450 strongly expressed in the stem and roots and down-regulated in the leaves when the plants were  
451 exposed to hydrogen peroxide and/or ABA treatments. Exogenous expression of *ZmNTL1*,  
452 *ZmNTL2*, and *ZmNTL5* in transgenic *Arabidopsis* led to increased tolerance to hydrogen  
453 peroxide in transgenic plants (Wang et al., 2016a). Overexpression of *ZmNAC55* in transgenic  
454 *Arabidopsis* resulted in plants which were hypersensitive to ABA at the seedling stage but  
455 showed enhanced resistance to drought when compared to the wild-type control seedlings (Mao  
456 et al., 2016). Additionally, twelve stress-responsive genes (*RD20*, *NCED3*, *ZAT10*, *ANAC019*,  
457 *LEA14*, *RD29B*, *RD29A*, *DREB2A*, *RD17*, *RD26*, *RAB18*, and *PP2CA*) were all up regulated in

458 response to drought stress in the transgenic lines (Table. 1). Expression profiles of *ZmNAC55* in  
459 maize revealed that this gene was induced by high salinity, drought, ABA and cold stress.

460 Elsewhere, seven NAC TF genes analyzed in maize seedlings (*Zma001259*, *Zma000584*,  
461 *Zma029150*, *ZmSNAC052*, *Zma003086*, *Zma054594*, and *Zma006493*) were all found to be up  
462 regulated in response to salt stress in all tissues (Lu et al., 2015). In response to PEG treatment,  
463 three of the above-mentioned genes, namely *Zma006493*, *Zma003086* and *Zma000584* were  
464 significantly up regulated in the roots only, while *Zma001259*, *Zma029150*, *Zma000584*, and  
465 *Zma054594* were all strongly expressed in both the roots and shoots. Five genes, *Zma054594*,  
466 *Zma000584*, *Zma001259*, *Zma003086*, and *ZmSNAC052* were activated by cold stress although  
467 in varying degrees. In conclusion, due to the strong expression in response to ABA treatments,  
468 these seven genes could play a vital role in the ABA-dependent signaling network in maize.

469 Numerous advancements in NAC TFs functional studies have been achieved over the past few  
470 years. However, most of these studies are related to the involvement of NAC TFs in biotic stress  
471 responses. To achieve a deeper understanding of NAC TFs in abiotic stress responses, it is of  
472 vital importance to identify the main components of signal transduction pathways that interact  
473 with these TFs. Utilizing data obtained from microarray analyses could help in the direct  
474 determination of specific NAC DNA- binding sites on a global scale under different abiotic  
475 stress conditions.

476 Finally, numerous studies have demonstrated the use of stress-responsive NAC TFs in the  
477 improvement of abiotic stress tolerance in crops by genetic engineering. In view of the  
478 specificity of NAC TF in multiple stress responses, NAC TFs that are induced by multiple  
479 abiotic stresses are promising candidates in the engineering of plant varieties with improved  
480 multiple stress tolerance (Shao et al., 2015). Moreover, field evaluation of engineered crops  
481 containing NAC TF genes and efficient promoters, for reducing detrimental effects triggered by  
482 overexpression of some NAC genes must be considered (Rushton et al., 2008).

483

#### 484 **bZIP TFs: AREB/ABF regulon**

485 The ABA-responsive element (ABRE; PyACGTGG/TC), is a conserved *cis*-acting element  
486 bound by the basic Leucine Zipper Domain (bZIP) TFs (Loredana et al., 2011). The ABRE was  
487 first established on the promoter region of ABA-activated genes by (Giraudat et al., 1994). The  
488 bZIP TFs, belong to one of the largest and diversified TF families in plants. They are categorized  
489 into ten subfamilies based on the presence of extra conserved motifs and the basic region  
490 sequence similarities (Perez-Rodrigues et al., 2010). AREB/ABF TFs are characterized by a  
491 strongly conserved bZIP domain made up of two structural components [a leucine (Leu) zipper  
492 and a basic region], the leucine (Leu) zipper is composed of heptad repeats of Leu and/ or other  
493 heavy hydrophobic amino acid residues and controls hetero- and or homodimerization of the  
494 bZIP proteins. The basic region is composed of 16 amino acids with the indistinguishable N-x7-  
495 R/K-x9 motif and is responsible for DNA binding and nuclear localization (Jakoby et al., 2002).  
496 The bZIP TFs, which are part of the AREB/ABF regulons, give an excellent example of  
497 interactions involving stress-responsive genes and TFs carrying the *cis*-acting element (ABRE).  
498 In maize, a bZIP TF gene *ABP9* that has the ability to bind to the AREB2 motif located in the  
499 *Cat1* promoter region was activated by drought, salt, H<sub>2</sub>O<sub>2</sub>, and ABA (Zhang et al., 2011).  
500 Exogenous expression of *ABP9* in *Arabidopsis* led to significant tolerance to freezing, salt,

501 oxidative stress and drought in transgenic plants. Transgenic *Arabidopsis* plants also showed  
502 enhanced sensitivity to exogenously supplied ABA during stomatal closure, seed germination,  
503 and root growth. Furthermore, transgenic plants expressing *ABP9* showed reduced levels of  
504 oxidative cellular damage, reduced cell death and reduced levels of ROS.

505 More recently, Wang et al. (2017) demonstrated that *ABP9* enhanced salt and osmotic stress  
506 tolerance in transgenic cotton plants. Overexpression of *ABP9* resulted in elevated transcripts of  
507 several stress responsive-genes (*GhNCED2*, *GhDBP2*, *GhZFP1*, *GhHB1*, *GhSAP1*, and  
508 *GhERF1*) in the transgenic cotton plants in response to salt stress (Table. 2). Additionally,  
509 transgenic plants were shown to have higher germination rates, and improved root systems in a  
510 greenhouse setting and reduced stomatal density and stomatal aperture in a growth room. Finally,  
511 the relative water content (RWC) and survival rate of the transgenic plants was significantly  
512 higher compared to the control plants in response to drought. Wang et al. (2012) demonstrated  
513 that expression of *ZmbZIP60* was highly activated by a wide range of stresses including ABA,  
514 high salinity, tunicamycin treatment and dehydration (Table. 1). In the wild-type *Arabidopsis*,  
515 over-expression of *ZmbZIP60* resulted in plants with enhanced tolerance to dithiothreitol (DDT)  
516 stress. Furthermore, Li et al. (2018) discovered a major QTL governing heat-induced *ZmbZIP60*  
517 expression and deduced that the upstream region of *ZmbZIP60* plays a vital role in regulating  
518 responses to heat stress in maize.

519 Similarly, Ying et al. (2011) cloned and characterized a maize bZIP TF gene designated as  
520 *ZmbZIP72*, which was induced by drought, ABA and high salinity stress (Table. 1). *ZmbZIP72*  
521 was differentially expressed in various organs in maize. Overexpression of *ZmbZIP72* in  
522 transgenic *Arabidopsis* led to enhanced tolerance to drought, partial tolerance to salinity and  
523 hypersensitivity to osmotic stress and ABA treatment. Furthermore, the transgenic *Arabidopsis*  
524 plants also showed enhanced expression of several ABA-inducible genes including (*RAB18*,  
525 *HIS1-3*, and *RD29B*). Elsewhere, microarray analysis of two specific maize inbred lines, a  
526 drought-sensitive Ye478 line, and a drought tolerant Han21 line revealed that 22 *ZmbZIP* genes  
527 might play a critical role in drought tolerance (Wei et al., 2012a). In the same report, *ZmbZIP37*  
528 an orthologous gene of two rice genes *OsbZIP72* and *OsbZIP23* that both play vital roles in  
529 drought tolerance and ABA response in rice, was found to be up-regulated in response to drought  
530 stress in maize. Similarly, cloning and characterization of a bZIP TF gene *ZmbZIP17* from the  
531 Han21 maize inbred line revealed that this gene was up regulated in response to drought (Jia et  
532 al., 2009). Real-time PCR analysis revealed that *ZmbZIP17* was highly up regulated in response  
533 to heat, salinity, drought, and ABA stresses immediately, suggesting that this gene represents an  
534 early responsive gene that reacts to various abiotic stresses. Elsewhere, expression analysis of  
535 two maize bZIP TF genes *ZmbZIP107* and *ZmbZIP54* revealed that these two genes were highly  
536 elevated in a lead tolerant maize line when compared to a lead sensitive line in response to  
537 different treatments of lead (Zhang et al., 2017) (Table. 1). Recently, Ma et al. (2018)  
538 demonstrated that *ZmbZIP4* was induced by drought, cold, high salinity, ABA, and heat in maize  
539 seedlings. Overexpression of *ZmbZIP4* led to an improved root system, increase in the number of  
540 lateral roots, and longer primary roots in transgenic maize. Additionally, genome-wide analysis  
541 of *ZmbZIP4* target genes by immunoprecipitation sequencing, unearthed a number of  
542 downstream stress response genes that were positively regulated by *ZmbZIP4*. These  
543 downstream target genes included *ZmRD21*, *ZmLEA2*, *ZmRD20*, *ZmGEA6*, *ZmNHX3*, and  
544 *ZmRAB18*. Collectively, these results suggested that *ZmbZIP4* is a positive regulator of abiotic  
545 stress response that takes part in root development in maize.

546 In conclusion, the promoter region of each abiotic stress responsive gene might carry a single or  
547 several proximal or distal coupling elements (CE) for instance, CE 3 and CE1 which activate the  
548 expression of abiotic stress-responsive genes. In addition, Shen et al. (1996) identified CEs in  
549 *Hordeum vulgare* that form an abscisic acid response complex (ABRC), which could be a  
550 necessary component in triggering ABA-mediated gene expression. Collectively, the above  
551 reports confirmed the participation of bZIP TFs in the ABA signaling pathway. These findings  
552 could be useful in the future development of better genotypes with improved tolerance to various  
553 abiotic stresses (Todaka et al., 2015). An accurate understanding of the functions of bZIP TFs in  
554 crops will require an accurate mapping of the location of bZIP genes in the different plant  
555 organs.

556

### 557 **WRKY TFs and WRKY regulons**

558 WRKY proteins represent the largest superfamily of TFs, which are specific to plants. WRKY  
559 TFs control plant growth and development and spur tolerance against both abiotic and biotic  
560 stresses (Tripathi et al., 2014). WRKY TFs are usually identified by a WRKY domain made up  
561 of 60 amino acid residues, and contains a highly conserved WRKYGQK sequence followed up  
562 by a zinc-finger motif. The WRKY domain shows a strong binding affinity for a *cis*-acting  
563 element known as W-box (TTGACC/T), which is present in a number of abiotic stress  
564 responsive genes (Rushton et al., 2010; Ulker and Somssich, 2004).

565 Several WRKY TFs involved in abiotic stress tolerance have recently been reported in maize.  
566 For example, functional analysis of *ZmWRKY33* under different abiotic stresses, revealed that  
567 this gene was activated by cold, dehydration, ABA and salt treatments (Li et al., 2013). Over-  
568 expression of *ZmWRKY33* in transgenic *Arabidopsis* led to the activation of two stress-activated  
569 genes (*RD29A* and *DREB1B*), which were both up-regulated resulting in enhanced salt tolerance  
570 in the transgenic plants (Table.1). The above-mentioned results strongly suggest that this maize  
571 WRKY TF plays a vital role in abiotic stress regulation in maize. Elsewhere, Wang (2013)  
572 demonstrated that exogenous over-expression of *ZmWRKY44* in transgenic *Arabidopsis* resulted  
573 in plants that were moderately sensitive to NaCl stress. In maize seedlings, *ZmWRKY44* was  
574 induced by high temperature, salt stress, ABA, and hydrogen peroxide treatments. Recently,  
575 *ZmWRKY17* was cloned, characterized and its expression was analyzed in maize seedlings (Cai  
576 et al., 2017) (Table. 1). The results showed *ZmWRKY17* was induced by ABA, salt and drought  
577 stresses. Additionally, constitutive expression of this gene in transgenic *Arabidopsis* led to a  
578 striking reduction in tolerance to salt stress, as confirmed by the physiological assays performed  
579 on relative electrical leakage, malondialdehyde (MDA) content, cotyledons greening rate and  
580 root growth. Still in the same study, RNA-Seq analysis showed that eight stress-related genes  
581 (*DREB1F*, *KIN1*, *bHLH92*, *RD29A*, *RD29B*, *NAC019*, *RD22*, and *MYB101*) were significantly  
582 up-regulated in the wild-type plants when compared to the transgenic plant lines in response to  
583 salt stress. However, expression of *NCED5* was higher in transgenic plants under the same stress.  
584 Together, these results give a strong indication that *ZmWRKY17* may function as a negative  
585 regulator in response to drought stress in maize. This could be due to elevated levels of ABA  
586 ensuing as a direct response to salt stress through the ABA signaling system. Wei et al. (2012b)  
587 compared the expression profiles of 31 WRKY genes in two maize lines, a drought-sensitive  
588 Ye478 line and a drought tolerant Han21 line. The results showed that the expression of the  
589 WRKY genes in the drought-tolerant Han21 line changed less, and the seedlings recovered faster

590 when re-watered, as opposed to the drought-sensitive Ye478 seedlings. In the same study, the  
591 expression of *ZmWRKY115* was decreased as a direct result of drought stress. Elsewhere, qRT-  
592 PCR expression analysis showed that *ZmWRKY58* was activated by salt, drought and ABA  
593 treatments (Cai et al., 2014) (Table. 1). Constitutive expression of *ZmWRKY58* in transgenic rice  
594 led to delayed germination and constrained post-germination growth and development. However,  
595 transgenic seedlings over-expressing *ZmWRKY58* reported increased tolerance to both salt and  
596 drought stresses (Table. 2). Similarly, Wang et al. (2018a) identified a WRKY TF gene named  
597 *ZmWRKY40* (Table. 1). A number of stress-related transcriptional regulatory factors were located  
598 in the promoter region of this gene. In maize, *ZmWRKY40* was induced by high salinity, drought,  
599 abscisic acid (ABA) and high temperature. Overexpression of *ZmWRKY40* in *Arabidopsis* led to  
600 enhanced drought tolerance in the transgenic plants. Additionally, overexpression of *ZmWRKY40*  
601 induced the expression of three stress-responsive genes *DREB2A*, *STZ* and *RD29A* in transgenic  
602 *Arabidopsis*. Recently, the expression of *ZmWRKY106*, a member of the WRKYII group was  
603 found to be induced by high temperature, drought, and exogenous ABA treatment, but was  
604 weakly induced by salinity (Wang et al., 2018c). Overexpression of *ZmWRKY106* in transgenic  
605 *Arabidopsis* led to improved tolerance to heat and drought. Additionally, *ZmWRKY106*  
606 positively regulated the expression of several stress response genes including *RD29A*, *CuZnSOD*,  
607 *DREB2A*, and *NCED6*. The above results strongly indicate *ZmWRKY106* may play an important  
608 role in the abiotic stress response pathways in maize by regulating stress-related genes.

609 In the model plant *Arabidopsis*, two WRKY genes WRKY 60 and WRKY 18 were found to  
610 regulate ABA signaling positively while one WRKY gene *WRKY40* negatively regulated ABA  
611 signaling. These three WRKY genes mentioned above, bind to the promoter region of several  
612 genes including some TFs genes like (*DREB1A/CBF3*, *ABI5*, and *DREB2A*), and several stress-  
613 regulated genes like (*COR47* and *RD29A*) in the process controlling their expression (Shang et  
614 al., 2010; Chen et al., 2010).

615 WRKY TFs have been identified as promising candidates for crop improvement due to the strict  
616 regulations involved in the identification and binding of these TFs to the downstream target  
617 promoter regions (Phukan et al., 2016). Taken together, all the above insights highlight the  
618 multiple stress responses and diverse regulation of WRKY TFs in maize and other crops.

619

## 620 **Other TFs and their Regulons**

621 Apart from the five main TF families described above, other TF families take part in diverse  
622 roles in plants including, regulating responses to both abiotic and biotic stresses, and various  
623 growth and development processes. Recently, extensive research has uncovered stress-mitigating  
624 roles of a number of TFs whose responses to abiotic stressors were previously unknown in  
625 maize. Three of these TF families are briefly described below.

626

## 627 **Homeodomain-leucine zipper I (HD-ZIP) I**

628 HD-Zip proteins represent a large TF family that is specific to plants. HD-Zip proteins have been  
629 cloned and characterized in several important crops and some model plants such as rice,  
630 *Arabidopsis*, tomato and sunflower (Johannesson et al., 2003; Lin et al., 2008; Agalou et al.,  
631 2008; Manavella et al., 2006). HD-Zip proteins are characterized by a DNA-binding

632 homeodomain (HD) and a neighboring leucine zipper (Zip) motif whose function is to mediate  
633 protein dimerization (Ariel et al., 2007). HD-Zip proteins belonging to the subfamily I are  
634 believed to take part in the majority of plant responses to abiotic stresses (Ariel et al., 2007). In  
635 *Arabidopsis* for example, analysis of four HD-Zip TFs (*ATHB6*, *ATHB7*, *ATHB5* and *ATHB12*)  
636 revealed that these genes were up-regulated or repressed by either ABA or drought stress  
637 (Soderman et al., 1996; Lee et al., 2001; Soderman et al., 1999; Johannesson et al., 2003). These  
638 results suggest that these four genes may play a vital role in the regulation of abiotic stress  
639 regulatory networks in plants.

640 In maize, *Zmhdz10* was the first HD-Zip TF to be isolated and characterized (Zhao et al., 2014).  
641 Expression of this gene was activated by abscisic acid (ABA) treatment and salinity stress  
642 (Table. 1). Exogenous over-expression of *Zmhdz10* in transgenic rice resulted in improved  
643 tolerance to salt and drought stress and enhanced sensitivity to ABA. Furthermore, the transgenic  
644 plants had elevated levels of proline and reduced malondialdehyde (MDA) content when  
645 compared to the wild-type plants (Table. 2). Transgenic *Arabidopsis* plants over-expressing  
646 *Zmhdz10* exhibited strong tolerance to salt and drought stresses, at the same time, expression  
647 patterns of several ABA-responsive genes namely (*ABI1*, *RD29B*, *P5CS1*, and *RD22*) were  
648 altered. The above results give a strong indication that *Zmhdz10* serves as a transcriptional  
649 regulator that can positively regulate both salt and drought stress tolerance in the ABA-  
650 dependent pathway in plants. Recently, Qing and Wei (2018) isolated and characterized a maize  
651 HD-ZIP TF designated as *Zmhdz12*. Tissue expression analysis revealed that this TF was  
652 strongly expressed in the leaves compared to other tissues. In transgenic *Arabidopsis*, *Zmhdz12*  
653 was activated by drought as observed when the drought resistant transgenic lines were compared  
654 to the wild-type lines. Similarly, expression status of 17 *Zmhdz* I genes from maize (*Zmhdz1* to  
655 *Zmhdz17*) revealed that all these genes were either repressed or up-regulated due to drought  
656 stress (Zhao et al., 2011). Additionally, many of the genes above belonging to the same subgroup  
657 in the phylogenetic tree, showed similar patterns of expressions. Elsewhere, *ZmHDZ4* was  
658 isolated and characterized in maize for its role in drought stress tolerance (Wu et al., 2016).  
659 Overexpression of *ZmHDZ4* in transgenic rice resulted in plants with enhanced tolerance to  
660 drought.

661 In conclusion, it is worth noting that HD-Zip proteins play crucial roles in cuticle formation, so  
662 they might be involved in abiotic stress tolerance and protection against plant pathogens (Chew  
663 et al., 2013). In addition, the roles described above make HD-Zip TFs ideal candidates for  
664 genetic engineering in maize and other major crops. Although more in-depth studies are needed  
665 in order to ascertain the function of individual HD-Zip family members in response to various  
666 abiotic stresses.

667

## 668 Heat Shock Proteins (HSPs)

669 All organisms are composed of an evolutionarily conserved, fast cellular defense system known  
670 as heat shock (HS) response, which regulates various reactions associated with heat stress and a  
671 variety of chemical stressors (Lin et al., 2011). HSPs were first discovered in the salivary glands  
672 of *Drosophila* in response to heat shock (Ashburner and Bonner, 1979). HSFs family members  
673 function by binding to the promoter of chaperones referred to as heat shock proteins. HSF TFs  
674 have a 3 N-terminal section and a C-terminal section in addition to leucine amino acid (Schuetz  
675 et al., 1991). HSPs can be categorized into six main families, (Hsp90, Hsp40, Hsp90, Hsp60,

676 Hsp70, and Hsp110) based on their molecular sizes (Wang et al., 2004). HSPs in plants were first  
677 characterized in tomato (Scharf et al., 1990), and since then more HSFs have been reported in  
678 other plants such as *Arabidopsis*, rice, sunflower and wheat (Hubel and Schoffl, 1994;  
679 Yamanouchi et al., 2002; Almoguera et al., 2002; Shim et al., 2009). A survey recently reported  
680 that there are at least 24 HSFs in *Brachypodium*, 21 in *Arabidopsis*, 30 in maize, 25 in rice, 52 in  
681 soybeans and 27 in tomatoes (Scharf et al., 2012). In the model plant *Arabidopsis*, a HsfA2  
682 mutant displayed tolerance to osmotic stress, salt, and heat stresses, suggesting that this gene is  
683 involved in several abiotic stress response networks and pathways (Ogawa et al., 2007).

684 Few HSPs gene have been isolated and characterized in maize. Jinhui et al. (2015) isolated and  
685 characterized a Hsp70 gene named *ZmERD2* (Early Responsive to Dehydration 2) from maize  
686 (Table. 1). Expression patterns of *ZmERD2* revealed that this gene was induced by cold, high  
687 salinity, dehydration, heat stress, and PEG but was not induced by abscisic acid (ABA). Further  
688 expression analysis revealed *ZmERD2* was instantly activated at 42°C and its peak was reached  
689 after 1 hour of exposure to heat stress. Elsewhere, expression patterns of 22 Hsf genes from  
690 maize showed that these genes were differentially expressed when subjected to heat stress (Lin et  
691 al., 2011). Further analyses from this study revealed that *ZmHsfA2* subclass in maize has close  
692 relations with heat shock response. This is after three HsfA2 genes (*ZmHsf-17*, *ZmHsf-01*, and  
693 *ZmHsf-04*) were strongly expressed in response to heat stress. In addition, six more genes were  
694 highly up-regulated in response to heat stress (*ZmHsf-03*, *ZmHsf-01*, *ZmHsf-23*, *ZmHsf-24*,  
695 *ZmHsf-04*, and *ZmHsf-25*). These results pointing to the specific roles these genes play in maize  
696 in response to heat stress. Li et al. (2015) recently cloned a maize HSF designated as *ZmHsf06*  
697 from maize and transformed it in *Arabidopsis thaliana*. Expression analysis of the transgenic  
698 plants over-expressing *ZmHsf06* revealed that this gene was induced by drought and heat stress  
699 (Table. 2). The above results were confirmed by biochemical and physiological evidence that  
700 showed that the transgenic plants displayed longer axial root length, higher seed germination  
701 rate, elevated levels of chlorophyll in leaves as well as reduced osmotic potential (OP) and  
702 malondialdehyde (MDA) content when compared to the wild-type plants. Based on the above  
703 results, it's evident *ZmHsf06* could have future potential use in molecular breeding in maize as  
704 well as other crops for improved drought and heat stress tolerance.

705 Collectively, it is important to mention that HSPs have been shown to have a close association  
706 with reactive oxygen species (ROS), meaning that plants have gained a stronger level of ROS  
707 regulation throughout the course of evolution (Banti et al., 2010). Therefore, understanding the  
708 roles played by HSPs in plant responses to abiotic stresses will be useful in the engineering of  
709 abiotic stress tolerant crop varieties. HSP have been studied and characterized in a number of  
710 important crop varieties as mentioned above, although their functional plasticity and genome  
711 sequence data is still limited (Echevarria-Zomeno et al., 2016).

712

### 713 **NF-Y Transcription Factors**

714 Nuclear factor Y also referred to as CBF (CCAAT binding factor) or heme activator protein  
715 (HAP), is a complex made up of three subunits NF-YB (CBF-A or HAP3), NF-YA (CBF-B or  
716 HAP2) and NF-YC (CBF-C or HAP5) (Nardini et al., 2013; Wang et al., 2018b). The NF-Y TF  
717 family has been comprehensively studied in animal systems, and it was found that each subunit  
718 is encoded by a single gene in yeast and mammals (Mantovani., 1999). NF-Y transcription  
719 factors interact with other factors in the regulatory network to induce or inhibit the expression of

720 downstream target genes (Benatti et al., 2008). Unlike mammals and yeast, plants have many  
721 NF-Y subunit genes (Wang et al., 2018b). For example, in *Arabidopsis* 13 genes encoding NF-  
722 YB, 10 genes encoding NF-YA and 13 genes encoding NF-YC have been reported (Siefers et al.,  
723 2009). Additionally, individual NF-Y subunits have been shown to play vital roles in plant  
724 abiotic stress tolerance (Sato et al., 2014; Ma et al., 2015).

725 Even though maize has numerous NF-Y subunits, very few studies have been done to investigate  
726 the roles these subunits play in response to abiotic stress (Wang et al., 2018b). Nelson et. (2007)  
727 demonstrated that transgenic maize with elevated levels of *ZmNF-YB2* showed improved  
728 tolerance to drought stress based on responses from various stress-related parameters which  
729 included stomatal conductance, chlorophyll content, reduced wilting and leaf temperature (Table.  
730 2). Recently, overexpression of a NF-YB transcription factor complex member designated as  
731 *ZmNF-YB16* resulted in improved drought and dehydration resistance in transgenic inbred maize  
732 line B104 during reproductive and vegetative stages (Wang et al., 2018b) (Table 1). Analysis of  
733 gene expression in the photosynthesis system between the WT and transgenic plants revealed  
734 that several genes were up-regulated in the transgenic plants when compared to the WT plants.  
735 Examples of genes up-regulated included GRMZM2G117572 (encoding the photosystem II  
736 PsbZ protein), GRMZM2G414660 (encoding the photosystem II cytochrome b599 subunit) and  
737 GRMZM5G831399 (encoding the photosystem II PsbH protein) among others.

738 Analysis of the co-expression between miR169, miRNA family and ZmNF-YA TFs in  
739 transgenic *Nicotiana bethamiana* revealed that mutations in deletion sites terminate the  
740 regulation of zma-miR169 (Luan et al., 2014). The expression levels of *zma-miR169l*, *zma-*  
741 *miR169i*, and *zma-miR169a* were all inversely correlated with *ZmNF-YA11*, *ZmNF-YA6*, and  
742 *ZmNF-YA7* over the short term. However, over the long term, the expression levels of all the NF-  
743 YA genes and miR169s decreased, revealing that *ZmNF-YA11*, *ZmNF-YA6*, and *ZmNF-YA7*  
744 could not have been regulated by zma-miR169 in response to PEG stress after 15 days. Majority  
745 of the zma-miR169s were up-regulated by external ABA and down-regulated by drought stress  
746 but showed an early increase in expression and later a decline in response to salinity stress.  
747 Recently, Su et al. (2018) identified a NF-Y TF designated as *ZmNF-YA3*. Genome-wide  
748 analysis revealed that *ZmNF-YA3* was linked to more than 6000 sites in the maize genome, 2259  
749 of which are linked with genic sequences. Moreover, it was shown that *ZmNF-YA3* could  
750 significantly improve high temperature and drought tolerance in maize by binding to the  
751 promoter region of three downstream genes (*ZmMYC4*, *ZmbHLH92*, and *ZmFAMA*).

752 In conclusion, all of the insights obtained above suggest NF-Y TFs play an important role in  
753 abiotic stress tolerance in maize by regulating several vital downstream genes involved in  
754 important aspects of abiotic stress responses, and plant growth and development, for instance,  
755 photosynthesis and ER stress response. Therefore, NF-Y TF genes could be engineered in maize  
756 and other crops in order to improve their abiotic stress tolerance, leading to improved production.

757

## 758 **Engineering of TFs**

759 The recent discovery of TFs as potential tools in the manipulation and engineering of  
760 quantitative traits such as drought and salinity has ignited the development of novel technologies  
761 based on TFs and benefiting not only gene discovery but also crop improvement. Engineering of  
762 TF activity has been a major target in these efforts, a direction that offers future promises in

763 modulating metabolic pathways. For example, over-expression of DREB2 resulted in no stress  
764 tolerance improvement because proteins are composed of domains that limit the induction of  
765 their target genes downstream (Liu et al., 1998). Sakuma et al. (2006) obtained drought-tolerant  
766 plants by removing this repressor function through the engineering of point mutations. An  
767 undesirable effect of overexpressing stress-related TFs is that sometimes it negatively affects the  
768 growth and development of a plant leading to stunted growth or toxicity (Hussain and Amjad,  
769 2011). Elsewhere, over-expression of *ZmDREB2A* under a stress-activated promoter in the  
770 transgenic plants led to significant improvement in drought tolerance (Qin et al., 2007).

771 Transcriptional down regulators that repress gene expression in response to various abiotic  
772 stresses are also important tools in manipulating drought tolerance. For example, over-expression  
773 of a yeast transcription repressor *CaZPF1* in *Arabidopsis* led to drought tolerance in transgenic  
774 plants (Kim et al., 2004). In the model plant *Arabidopsis*, systematic analysis of TF families  
775 resulted in the discovery of target genes that have the potential to enhance abiotic stress tolerance  
776 in major crops (Reichmann et al., 2000). A good example is the discovery of *AtNF-YB1* gene that  
777 belongs to the Nuclear factor Y TF family (Nelson et al., 2007). The orthologue of (*AtNF-YB1*)  
778 gene in maize, (*ZmNF-YB2*) when over-expressed in transgenic maize, resulted in drought-  
779 tolerant crops (Table. 2). These findings emphasized the significance of TFs, especially when  
780 used in the engineering of plants.

781 The abiotic stress response networks in plants are very complex due to the large number of gene  
782 families involved and the complicated associations between the *cis*-acting elements and the TFs.  
783 In addition, a single TF may regulate a large number of target genes with similar *cis*-elements  
784 whereas TFs from different families may regulate a single target gene with different types of *cis*-  
785 acting elements (Hussain and Amjad, 2011). Therefore, abiotic stresses regulating TFs not only  
786 function independently but also co-regulate abiotic stress responses between each other (Wang et  
787 al., 2016b) (Fig. 2). As mentioned throughout this review, genetic engineering of TF genes will  
788 be much more significant than manipulating a single functional gene. Thereafter, validation of  
789 the identified genes should be performed in model crops as well as the main crops by utilizing a  
790 stress-inducible promoter to reduce the detrimental effects brought about because of over-  
791 expression of certain TFs (Lan et al., 2017). Moving forward, all of these advances will help  
792 elucidate the detailed regulatory channels taking part in multiple abiotic stress responses in  
793 plants, leading to the acquisition of target TF genes for enhanced breeding of abiotic stress-  
794 tolerant plants with improved desirable qualities and yields.

795

## 796 **Current and post genomics approaches**

797 Abiotic stresses represent a combination of various distinct traits consisting of a quantitative  
798 pattern of inheritance. Therefore, in order to efficiently understand the plants response to the  
799 different abiotic stresses at the molecular level, a deeper understanding of the systems involved  
800 in transcription regulation is required. Trait mapping, functional characterization, genomic  
801 selection, rapid RNA and DNA high-throughput SNP genotyping tools, sequencing technologies,  
802 and other platforms are currently used to analyze the genetic mechanisms of different abiotic  
803 stresses including drought, salinity, and cold in an effort to speed up the breeding process in  
804 maize (Nepolean et al., 2018).

805 Genome editing techniques are the most recent technologies applied in gene function analyses  
806 and manipulations. RNA interference (RNAi) is a rapid and inexpensive technique utilized to  
807 analyze gene function in targeted gene knockdown analyses (Rabara et al., 2014). However, a  
808 disadvantage of this technique is that the inhibition of gene function is not complete and this  
809 could lead to unintended off-target effects leading to misinterpretation of results (Gaj et al.,  
810 2013). Of the targeted genome editing approaches currently available, clustered regulatory  
811 interspaced short palindromic repeats ‘CRISPR’ is the most effective system used in editing  
812 plant genomes (Cong et al., 2013). CRISPR artificial transcription factors (CRISPR-ATFs) are  
813 gaining popularity as an effective system for regulating in vivo plant gene expression (Lowder et  
814 al., 2018). For instance, two novel systems (CRISPR-Act2.0 and mTALE-Act) were developed  
815 that could be used to study gene regulatory networks and the control mechanisms involved in  
816 plants (Lowder et al., 2018).

817 The other systems are transcription activator-like effectors nucleases (TALENs) (Boch et al.,  
818 2009) and Zinc-finger nuclease (ZFNs) (Kim et al., 1996). Another approach with huge  
819 potentials in functional genomics in plants is targeting-induced local lesions in genomes  
820 (TILLING). For example, a TILLING approach known as ecotilling, which was used to identify  
821 variations in natural populations, was successfully used to identify TFs in rice associated with  
822 drought tolerance (Yu et al., 2012). These techniques are vital in the selection of better quality  
823 genotypes and target genes in the abiotic stress tolerance research in maize.

824 Another approach currently being explored is the use of machine learning in the study of TFs  
825 gene regulatory networks. Predictions of TF binding sites (TFBSs) and their corresponding  
826 transcription factor target genes (TFTGs) using machine learning approaches has made  
827 substantial contributions to the study of gene regulatory networks (Cui et al., 2014).  
828 Understanding the interplay between TFs, TFBSs and TFTGs is vital in understanding the  
829 mechanisms involved in the gene regulatory processes taking place during biotic and abiotic  
830 stress responses in plants. Various computational algorithms are available in form of software  
831 packages. Additionally, expansive use of these software packages has revealed that even though  
832 some techniques were developed for one species, the same techniques can be used to analyze the  
833 dataset from other species (Cui et al., 2014). For example, a combination of Context Likelihood  
834 of Relatedness algorithm analyzed on *Escherichia coli* (Faith et al., 2007), Double Two-way t-  
835 tests algorithms analyzed on *Escherichia coli* and Learning Module Networks algorithm tested  
836 on yeast (Joshi et al., 2009) was used to identify the presence of oxidative stress regulatory  
837 transcription factors in Arabidopsis (Vermeirssen et al., 2014). Moreover, The Algorithm for the  
838 Reconstruction of Gene Regulatory Networks (ARACNE) (Margolin et al., 2006) was  
839 established to deduce transcriptional regulations in human immune B cells, but was later used to  
840 deduce transcriptional interactions regulating root physiological and developmental processes in  
841 Arabidopsis (Chavez et al., 2014).

842 Gene regulatory networks (GRNs) provide insights into the relationships between TFs and their  
843 corresponding target genes (Koryachko et al., 2015). For instance, network component analysis  
844 (NCA), a computational method developed for analysis of TF-gene interactions in microbial TF-  
845 GRNs, was employed to quantitatively analyze TF-GRNs critical in floral development in  
846 Arabidopsis (Misra and Sriram, 2013). The results showed that the NCA model adequately  
847 accounted for the total gene expression analysis in a TF-GRN of seven TFs (AG, HY5,  
848 SEPALLATA3, AP3/P1, AG, AP2, and AGL15) and 55 genes. Strong interactions were present  
849 between different TF- gene pairs, such as, *LFY* and *MYB17*, *AG* and *CRC*, *AP2* and *RD20*,

850 *AGL15* and *RAV2* and finally *HY5* and *HLH1*. In maize, a machine learning algorithm GENIE3  
851 was used together with numerous RNA-Seq expression data to establish a four tissue (root,  
852 SAM, seed, and leaf) specific GRNs (Huang et al., 2017). The results showed that even though  
853 many TFs were expressed in multiple tissues, a multi-level examination predicted regulatory  
854 roles for many TFs. Additionally, 76.6% (30,028/39479) of the genes were found to be  
855 expressed in all the maize tissues. Out of the total of 2587 TFs annotated by GRASSIUS in  
856 maize (Chen et al., 2013), 54.46% were expressed in all the four tissues while 86.63% of the  
857 total TFs were expressed in at least one of the four tissues.

858 Understanding the mechanisms of gene regulatory networks (GRNs) is vital in gaining insights  
859 on how TFs control gene expression in response to various abiotic stresses. Wet lab experiments  
860 are technically demanding, time-consuming and financially demanding (Penfold and Wild,  
861 2011). Many machine-learning approaches have been proposed with an aim of reducing costs  
862 and time spent in the prediction of GRNs. For instance, recent development of a publicly  
863 accessible maize TF ORF collection (TFome) consisting of 2034 clones that correspond to 2017  
864 unique maize TFs and co-regulators (CoREGs), has vastly contributed to the better  
865 understanding of GRNs (Burdo et al., 2014). The TFome was generated from a set of full cDNAs  
866 (FL-cDNA) obtained from the Arizona Genomics Institute (AGI). The synthesis information,  
867 generated sequences, and request links for the maize TFome information are publicly available  
868 through GRASSIUS (<http://grassius.org/tfomecollection.html>). In conclusion, adaptation of  
869 available crop databases such as Gramene (Tello-Ruiz et al., 2018), and GRASSIUS for maize in  
870 machine learning approaches, as well as developing and adopting new databases for example the  
871 Wheat Information System (WheatIS) (Hu et al., 2018) will help in the storage of data at the  
872 same time making it more accessible to scientists.

873 Traditional breeding techniques for selecting desirable traits depend on the observed phenotypic  
874 traits which can be misleading sometimes during selection, and this has led to low success in  
875 such strategies. Genomic selection is an accurate and efficient approach when it comes to the  
876 prediction of genotypic performance in crops. In maize, utilization of genomic techniques in the  
877 manipulation and analyses of TFs has been reported in a few studies. For instance, Mittal et al.  
878 (2017) utilized genomic selection techniques on 240 subtropical maize lines during exposure to  
879 drought by selecting 29,619 SNPs. The study found that 77 out of 1053 SNPs were linked with  
880 10 drought associated TFs located inside a 150 kb area. For example, MYB (149Kb), WRKY  
881 (125Kb), NAC (149Kb), bZIP (92Kb), and AP-ERF (148 Kb) among others. Similarly,  
882 transcriptome analysis of two maize inbred lines using RNA-Seq showed that a total of 2558 and  
883 555 genes responded to drought in both the sensitive and the tolerant lines respectively (Zhang et  
884 al., 2017a). TFs were found to be enriched in the genotype-specific responsive genes, and the  
885 genotypic differentially expressed genes. It was postulated that the differential expression of 22  
886 TF genes and the genotype-specific response of 20 TFs in the tolerant line might play an  
887 important role in drought tolerance enhancement in maize. Zhang et al. (2017b) utilized RNA-  
888 Seq platform to analyze the expression of TFs in response to lead stress in a maize 178 lead-  
889 tolerant line. In this study, a total of 464 genes were expressed, among which 262 differentially  
890 expressed TFs (DETs) which responded to Pb treatment were identified. More recently, (Zhao et  
891 al., 2018) mapped several abiotic stress responsive TFs to QTLs. The results showed that *MYB78*  
892 and *hsp70* were mapped to mQTL1-5. On chromosome 6, *pep7* and *mlip15* were both mapped on  
893 mQTL6-1. Kusano et al. (1995) demonstrated that *mlip15* was a low-temperature activated gene  
894 that encodes a bZIP protein made up of 135 amino acid. Elsewhere, global transcriptome

895 profiling using RNA-seq on B73 maize seedlings exposed to heat, drought, cold stress, and  
896 salinity revealed 5,330 differentially expressed genes (DEGs) (Li et al 2017). Functional  
897 annotations of these DEGs suggested that the pathways involving TFs, hormone metabolism and  
898 signaling among others controlled the stress responses. Among the 5,330 DEGs obtained, 167  
899 genes were common to the four abiotic stresses; these included two down-regulated TFs (one  
900 MYB related and one b-ZIP) and 10 up-regulated TFs (one ARF, five ERFs, one MYB, one HD-  
901 ZIP, and two NAC). This study significantly contributes to a deeper understanding of molecular  
902 mechanisms involved in maize leaf responses to different abiotic stresses and could eventually  
903 contribute to the development of maize cultivars that are tolerant to various abiotic stresses.

904 Approaches involving genome-editing techniques create possibilities allowing for gene  
905 knockouts, point mutations, epigenetic changes, and the activation or repression of genes  
906 (Kamburova et al., 2017). Svitashv et al. (2016) reported the use of biolistic delivery of Cas9-  
907 gRNA ribonucleoproteins in maize cells, and this approach resulted in plants with both edited  
908 and mutated alleles. Recently, (Cox et al., 2017) reported the use of single-effector  
909 programmable RNA guided RNases Cas13. This marks a major leap in plant transformation  
910 opening new opportunities in accelerated breeding in other main crops such as wheat, soybeans,  
911 sorghum, and rice. By using the RNA editing tools, the DNA structure is left intact but the  
912 function of the TF genes is manipulated. Utilization of genome editing techniques is still in its  
913 infancy and it is yet to be fully explored for abiotic stress tolerance in maize.

914

## 915 **Future outlook**

916 Recent advances in genomics, molecular biology, metabolomics and proteomics have yielded  
917 fresh insights into the plant gene regulatory network, composed mainly of regulatory elements  
918 (*trans*-elements and *cis*-elements), inducible genes (developmental and environmental cues),  
919 varying signal factors and complementary biochemical pathways (Tang et al., 2003; Wang et al.,  
920 2003; Zhu., 2002). Sequencing of the whole maize genome has provided a basis for the  
921 functional characterization and identification of genetic networks and genes for maize  
922 improvement (Schnable et al., 2009). Moreover, recent availability of transcriptome profiling  
923 technologies, including genome sequencing and DNA microarrays, has opened new doors for  
924 understanding the patterns of transcription in the area of plant growth and development (Sekhon  
925 et al., 2011).

926 Understanding the genetic architecture of the molecular networks involved in maize, by utilizing  
927 current “OMICS” technologies is urgently needed to unravel the drought, heat and salt tolerance  
928 mechanisms in maize. Numerous genetic studies have shown that abiotic stress tolerance traits  
929 are usually polygenic making the selection of such traits extremely difficult (Loredana et al.,  
930 2011). With the recent whole-genome sequencing of the B73 maize line, it’s now feasible to  
931 identify most maize TFs and systematically estimate their contribution to abiotic stress tolerance.  
932 Maize has an increased level of genetic disequilibrium linkage (LD) and genetic diversity  
933 making it an ideal plant species since the LD and genetic diversity have been predicted to be  
934 within a number of kilobases (kbs) in maize landraces (Tenaillon et al., 2003). This  
935 characteristic makes genome-wide association studies (GWAS) at the gene level more accurate  
936 when compared to self-pollinated plant species as long as genome-wide and high-density DNA  
937 markers are present (Yan et al., 2011; Li et al., 2012). For example, using a Bayesian-based  
938 genome-wide association method in which RNA-seq-based systems of transcript buildup were

939 utilized as explanatory variables (eRD-GWAS), genes linked to 13 traits were discovered from a  
940 group of 369 inbred maize lines (Lin et al., 2017). Additionally, TFs were found to be  
941 considerably enriched among the trait-associated genes discovered with eRD-GWAS. Similarly,  
942 genome-wide analyses carried out on the maize B73 inbred line to identify all the Hsf genes  
943 identified 25 non-redundant Hsf genes designated as *ZmHsfs* (Lin et al., 2011). In soybean, an  
944 all-inclusive phylogenetic study revealed 58 dehydration responsive genes from the *GmNAC* TF  
945 family (Le et al., 2011). RNA sequencing performed on 14-day old maize seedlings of inbred  
946 lines Mo17, B73, PH207, B37 and Oh43 under heat, cold and control treatments, revealed a large  
947 number of genes that responded differentially between parental inbred lines (Waters et al., 2017).  
948 Moreover, 20 of the 57 annotated TF families in maize were enriched for elevated genes in heat  
949 and/or cold stress in at least three of the five inbred genotypes. Finally, TF families with TFs that  
950 were enriched for up-regulated genes in response to heat stress included MYB and HSF TF  
951 families, while 18 TF families with TFs enriched for up-regulated genes in response to cold  
952 stress included APETALA2/ (AP2/EREB).

953 A new approach currently gaining rapid popularity is the field of phenomics. By utilizing high-  
954 throughput phenotyping, various physiological parameters such as biomass, internode length,  
955 leaf area, chlorophyll content, plant width and height, and growth rate can be accurately  
956 determined in real time and noninvasively (Rabara et al., 2014). Large amounts of quality  
957 phenomics data can be generated for many transgenic plants. Currently, field phenotyping  
958 systems are being developed with the capacity to determine whether the engineering of TFs in  
959 plants can improve abiotic stress tolerance (Rabara et al., 2014). For instance, Awlia et al. (2016)  
960 demonstrated that the phenotyping of polygenic traits in one experimental study could provide  
961 new insights into the mechanisms of plant responses to different abiotic stresses. The  
962 establishment of new phenomics technologies will further strengthen the use of forward genetics  
963 in the identification of novel TF genes regulating plant responses to different abiotic stresses.

964 Since TFs tend to regulate multiple pathways as opposed to a majority of the structural genes,  
965 they offer a powerful and unique system for use in the control of complex regulatory networks in  
966 plants. Over-expression of genes regulating the transcription of several down-stream  
967 abiotic/drought stress regulatory genes is a much better approach in the engineering of drought  
968 tolerant/resistant plants as opposed to the development of specific functional genes (Bartels and  
969 Hussain, 2008). Development of transgenic plants with enhanced abiotic stress tolerance by  
970 regulating TFs has become an important aspect of abiotic stress tolerance. Members of the  
971 WRKY, MYB, AREB, and bZIP, TF families have recently been utilized in the regulation of  
972 abiotic stress responses in major crops (Singh et al., 2002). Many of the members belonging to  
973 these TF families have been identified and characterized in *Arabidopsis*, whose genome has been  
974 analyzed using microarray analysis, thus leading to the discovery of potential genes (Shinozaki.,  
975 2003; Bray., 2004; Denby and Gehring, 2005). Thus TF families offer important targets for use  
976 in gene manipulation and regulation which could be vital in understanding responses involved in  
977 abiotic stress tolerance. An increasing trend has seen the engineering of TFs involved in stress-  
978 signaling networks using biotechnology tools to generate transgenic stress tolerant plants. (Abe  
979 et al., 2003; Sakuma et al., 2006).

980

981

982

983

984 **Conclusion**

985 The population in our planet is projected to rise to 9 billion by the year 2050 (Hussain., 2006),  
986 together with the rapid changes in climate there is an urgent need to speed up the productivity of  
987 major crops. Understanding molecular mechanisms and mining stress-responsive genes that  
988 control plant responses to different abiotic stresses is a major prerequisite in the development of  
989 stress-resistant and high yielding crop varieties (Khan et al., 2018). To safeguard the global food  
990 production, crops (like maize) that are well adapted to adverse environmental conditions should  
991 be established (Vinocur and Altman, 2005).

992 Maize is highly affected by abiotic stresses especially drought throughout its growth cycle, with  
993 the most damage being seen during the developmental stage and prior to flowering (Claassen and  
994 Shaw, 1970). TF mediated research in plants has recently shown progressive improvement since  
995 most of the TF encoding genes are early stress-responsive genes which control the expression of  
996 various downstream target genes (Lan et al., 2017). This has in turn led to a deeper  
997 understanding of the involvement and functions of TFs in plant responses to different abiotic  
998 stresses (Bartels and Sunkar, 2005).

999 This review emphasizes on the main TF families and their potential in abiotic stress tolerance in  
1000 maize. The majority of the TF genes in the literature are reported to play major roles in multiple  
1001 abiotic stress tolerances. Among the target genes for engineering, the utilization of TFs has been  
1002 recommended as they have potential to revolutionize biotechnology upon which novel crops with  
1003 improved tolerance to abiotic stresses could be successfully generated. There is absence of  
1004 literature available on abiotic stress responsive TFs with agronomic traits that have been utilized  
1005 in maize in field conditions. Although Monsanto has developed, a biotechnology-derived inbred  
1006 maize line that expresses HB17 (ATHB17), a TF from *Arabidopsis* (Park et al., 2013; Hymus et  
1007 al., 2013). Expression of ATHB17 in the inbred line is linked with increased ear biomass at the  
1008 silking stage compared to the near-isogenic controls (Rice et al., 2014). Increased ear biomass at  
1009 the early stage of plant development is associated with increased sink size and greater grain yield  
1010 from hybrid maize (Borras and Wetgate, 2006; Lee and Tollenaar, 2007).

1011 TFs are excellent candidates for the development of transgenic crops because of their roles in  
1012 plant growth and development. Incorporation of abiotic stress response pathways in the vital  
1013 reproductive and vegetative development stages in crops is an efficient strategy to improve  
1014 productivity in field conditions (Nelson et al., 2007). TFs can be used to simulate a variety of  
1015 developmental and biochemical networks that take part in the regulation of abiotic stresses, thus  
1016 increasing the performance of crops in response to multiple plant abiotic stresses. Joshi et al.  
1017 (2016) noted that over-expression of several TF genes significantly enhanced abiotic stress  
1018 tolerance but at the same time caused a number of negative effects including lower yields, late  
1019 flowering and dwarfing in transgenic plants. This should be considered in future studies to  
1020 maximize the effectiveness of TF engineering in responses to different abiotic stresses.

1021 Moving forward, identification and characterization of multiple stress regulatory genes should be  
1022 given more focus not only in maize but also in other major crops to target the most effective  
1023 genes that can be universally used to develop abiotic stress tolerant crop varieties. Machine  
1024 learning algorithms can be integrated with transcriptome data and high-throughput phenotyping

1025 data to further increase the automation of the gene discovery processes such as genome  
1026 annotation and gene regulatory networks (GRNs) predictions.

1027 Genetic engineering of multiple stress regulatory TF genes is a strong candidate for the  
1028 enhancement of stress tolerance in plants when compared to focusing on a single individual  
1029 gene. Nevertheless, recent advances in maize breeding, genomics and functional analysis of  
1030 genes combined with high-throughput sequencing technologies have significantly increased the  
1031 chances of achieving multiple stress tolerances. The identification of commercial transgenic  
1032 plants with enhanced crop performance under stress conditions is a tedious, expensive and  
1033 lengthy process. However, the successful genetic engineering of maize for improved abiotic  
1034 stress tolerance using TFs as reviewed herein confirms this approach is feasible.

1035 Since maize is a major crop in many countries, there is need for more collaboration in both  
1036 applied and theoretical genomics in order to improve the production of maize. The rapid  
1037 advancements in TFs genome analysis currently being witnessed are mostly on temperate maize  
1038 varieties. It is hoped that these technologies can be transferred to subtropical and tropical maize  
1039 varieties that serve as essential food security crop in developing countries.

# Figure 1

A diagrammatic representation of gene expression and abiotic stress signal perception in plants via ABA-independent and ABA-dependent pathways.

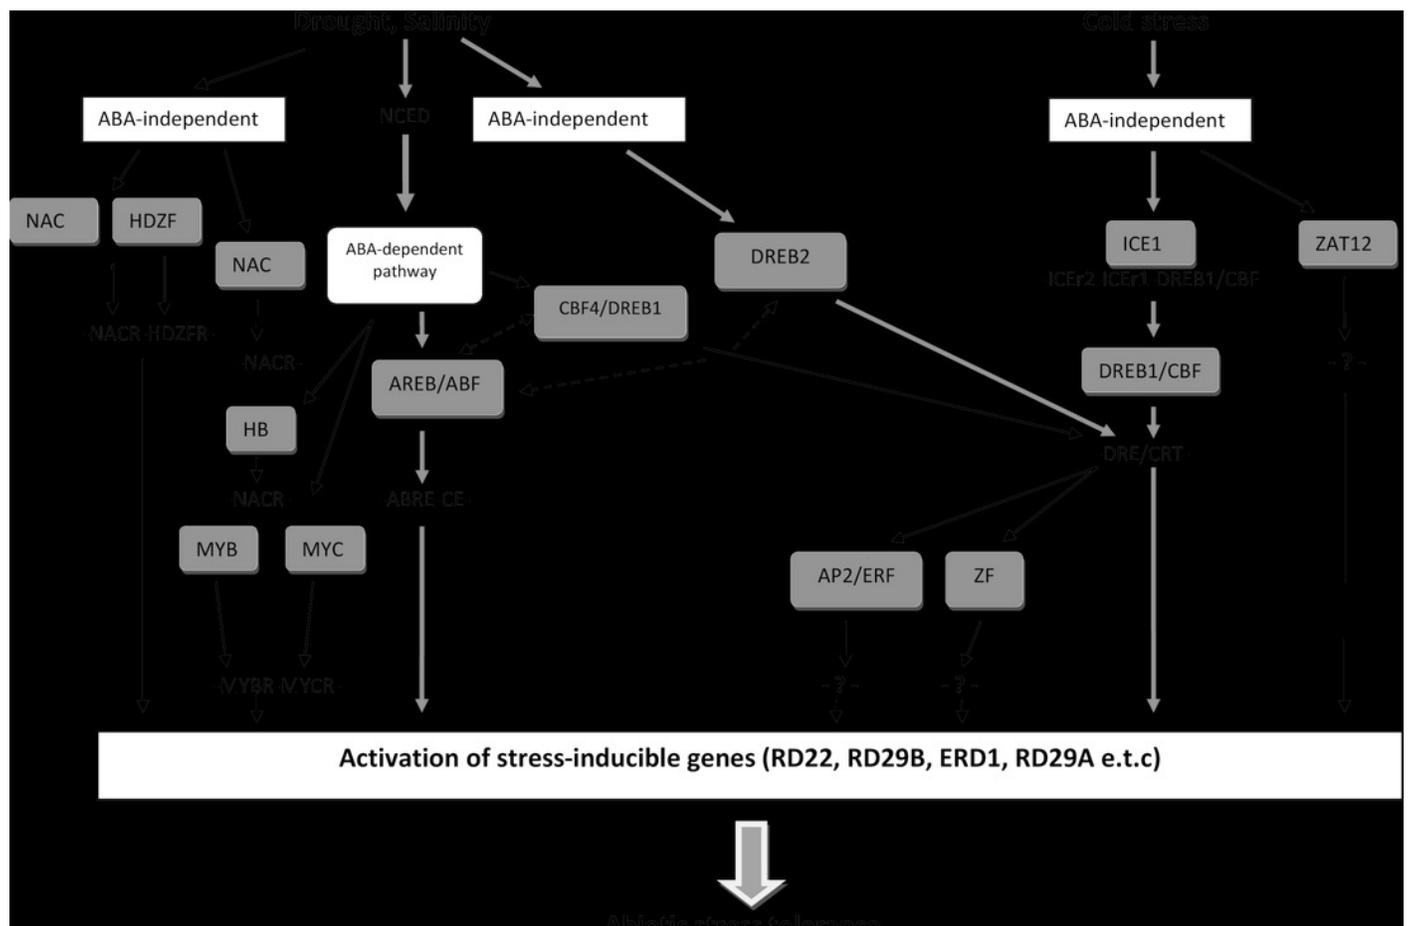

**Figure.1** A diagrammatic representation of gene expression and abiotic stress signal perception in plants via ABA-independent and ABA-dependent pathways (Modified from Gahlaut et al., 2016; Khan et al., 2018). Abbreviations: Abscisic acid (ABA), Reactive oxygen species (ROS), myeloblastosis oncogene (MYB), myelocytomatosis oncogene (MYC), Zinc-finger homeodomain (ZF-HD) regulon, ABA-responsive element binding protein (AREB), ABA-independent regulons include; the NAC (CUC, NAM and ATAF), The cis-acting element (DRE), ABA-binding factor (ABF), The cis-acting element (CRE), Dehydration responsive element binding proteins (DREBs), C-repeat (CRT), (ZFR) zinc finger RNA binding protein, (NARC) NAC recognition site, (MYBRS) MYB recognition site, (MYCRS) MYC recognition site, Nuclear transcription factor Y (NF-Y), Heat Shock Factors (HSFs), Inducer of CBF Expression (ICE).

## Figure 2

Cross-talk network between *cis*-acting elements and TFs in the ABA-independent and ABA-dependent pathways during abiotic stress

Cross-talk network between *cis*-acting elements and TFs in the ABA-independent and ABA-dependent pathways during abiotic stress. Broken arrows indicate the protein-protein interactions. Thick green arrows show the major pathways which regulate many downstream genes (modified from Yamaguchi-Shinozaki and Shinozaki, 2006).

**Table 1** (on next page)

Abiotic stress- related TF families, together with the specific TFs in Maize.

Abiotic stress- related TF families, together with the specific TFs, their characteristics, the regulons they control and their regulatory functions in the abiotic stress responses in Maize.

- 1 **Table 1** Abiotic stress- related TF families, together with the specific TFs, their characteristics,  
 2 the regulons they control and their regulatory functions in the abiotic stress responses in Maize.
