38   **Abstract**
39   In 2010, the Conference of the Parties of the Convention on Biological Diversity agreed on the
40   Strategic Plan for Biodiversity 2011-2020 in Aichi Prefecture, Japan. As this plan approaches its
41   end, we discussed whether marine biodiversity and prediction studies were nearing the Aichi
42   Targets during the 4th World Conference on Marine Biodiversity held in Montreal, Canada in June
43   2018. This article summarises the outcome of a five-day group discussion on how global marine
44   biodiversity studies should be focused further to better understand the patterns of biodiversity. We
45   discussed and reviewed seven fundamental biodiversity priorities related to nine Aichi Targets
46   focusing on global biodiversity discovery and predictions to improve and enhance biodiversity
47   data standards (quantity and quality), tools and techniques, spatial and temporal scale framing, and
48   stewardship and dissemination. We discuss how identifying biodiversity knowledge gaps and
49   promoting efforts have and will reduce such gaps, including via the use of new databases, tools
50   and technology, and how these resources could be improved in the future. The group recognised
51   significant progress toward Target 19 in relation to scientific knowledge, but negligible progress
52   with regard to Targets 6 to 13 which aimed to safeguard and reduce human impacts on biodiversity.

53
54

55   **Introduction**

56

57   The 'Strategic Plan for Biodiversity 2011-2020' of the Convention on Biological Diversity was
58   agreed during the 10th Conference of the Parties, held from 18 to 29 October 2010, in Aichi
59   Prefecture, Japan. The strategic plan included five main "Strategic Goals" that were divided into
60   20 targets. Each 'Aichi Target' was designed to better understand and predict biodiversity
61   dynamics, such as how biological diversity underpins ecosystem function, and how the provision
62   of ecosystem services is essential for human well-being. Meeting the Aichi Targets would
63   ultimately benefit local livelihoods and economic development, and is essential for biodiversity
64   maintenance and poverty reduction (Shepherd et al. 2016; Tittensor et al. 2010). In this paper, we
65   report on the findings of a working group that discussed how the targets related to marine
66   biodiversity were being achieved.

67

68   **Survey Methodology**

69

70   The 4th World Conference on Marine Biodiversity (WCMB 2018) in Montreal organised a
71   working group to review and evaluate how the Aichi Targets have been met by the global
72   community. In particular, the review group was asked to focus on Target 19 regarding scientific
73   knowledge about biodiversity as this was the area of most expertise of the participants. To identify
74   and reduce biodiversity knowledge gaps we examined how marine biodiversity discoveries and
75   their predictions need to be redirected to better understand and predict how marine biodiversity
76   will change within the next 10 years. Here, we identify seven important priorities for this topic to
77   support the Aichi Targets (Table 1). These foci arose iteratively from discussion between the group

78 members and other groups at the conference. The priorities address issues of (1) data standards,
79 (2) education in data management, (3) taxonomic expertise, (4) genetic tools, (5) international
80 collaboration, (6) identifying knowledge gaps and understanding biogeography, and (7) the need
81 to reduce human pressures on marine biodiversity.
82
83 **Results and Discussion**
84 *Reviewed Priorities*
85
86 **1. Developing, improving and enhancing biodiversity data standards, exchange, and**
87 **analytical tools, via standardized techniques.**
88
89 Recent marine biodiversity discoveries have been greatly enhanced by standardised open-access
90 taxonomic and biogeographic data repositories such as the World Register of Marine Species
91 (WoRMS) and the Ocean Biogeographic Information System (OBIS) (Ahyong 2018; Costello et
92 al. 2013a). Large-scale development of marine biodiversity data standards and exchange started
93 when the Census of Marine Life (2000-2010) established OBIS (O'Dor et al. 2012).
94 Biodiversity data standards, such as "Darwin Core", a data schema that provides stable
95 terms and vocabularies for universal sharing of biodiversity data, and management techniques have
96 been improved to ensure that published data have high quality. For example, there are now
97 available taxonomic and geographic data management tools and R packages, e.g., rOBIS (Provoost
98 P 2018) (Figure 1). The taxon match tool in WoRMS can automatically check the correct spelling,
99 authority, classification and validity of species names uploaded to a webpage (Costello et al.
100 2013a). A marine gazetteer matches place names to geographic coordinates and polygon
101 (shapefiles) of localities (Claus et al. 2014). The standardization and open storage of metadata,
102 taxonomic, genetic, and geographic data also allows for greater stewardship by stakeholders,
103 enhanced public awareness and education, and importantly, the ability to easily share data among
104 institutions (Figure 1).
105 Developing biodiversity data standards and data exchange protocols enables both data
106 users and providers to benefit from the high-quality data that later allow for more reliable and
107 precise biodiversity analyses. The expansion of the OBIS data schema to include additional
108 information associated with sampling events, including sampling methods and environmental data,
109 is a significant recent advance (De Pooter et al. 2017). The open-access publication of thousands
110 of data sets integrated into OBIS has enabled major advances in our understanding of global
111 patterns of biodiversity. For example, several studies have utilized open-access marine species
112 distribution records to discover and confirm large-scale biodiversity patterns. These findings
113 include observations that global species richness is bimodal with latitude, and that species richness
114 decreases with depth (Chaudhary et al. 2016a; Chaudhary et al. 2017; Costello & Chaudhary
115 2017a; Saeedi et al. 2017a; Saeedi & Costello 2019a; Saeedi & Costello 2019b; Saeedi et al.
116 2017b). We conclude that there has been noticeable progress towards achieving the potential of
117 Aichi Target 19 through establishing global databases and taxonomic resources. These are leading

118   to better quality control, data management efficiencies, and new insights into our understanding
119   of biodiversity. However, these benefits, as well as contributions to these resources, are not
120   realised in all countries.

121

122   **2. Educational activities to increase data mobilisation by taxonomists, data users, and/or**
123   **wider audiences.**

124

125   Many scientists and the general public around the world are unaware of the presence and
126   advantages of large-scale open-access databases. Even if scientists are familiar with these
127   facilities, data preparation and submission can be complex for contributors unfamiliar with data
128   publication protocols. These issues are more pronounced for scientists in developing countries or
129   non-native English speakers. As a result of these perceived and real data publication obstacles,
130   significant biodiversity and biogeography knowledge remains in personal databases and non-
131   digital archives. These logistical hurdles and data ownership perceptions frequently stand in the
132   way of data publication. To expose researchers to these resources, initiatives like OceanTeacher
133   Global Academy (OTGA) (https://classroom.oceanteacher.org) or Ocean School
134   (https://oceanschool.nfb.ca/) provide a valuable educational platform that aids sustainable
135   development. OceanTeacher is part of the International Oceanographic Data and Information
136   Exchange (IODE) Programme of the Intergovernmental Oceanographic Commission (IOC) of
137   UNESCO. It has trained nearly 2,000 students from 120 countries since 2005
138   (https://classroom.oceanteacher.org/mod/page/view.php?id=2033). OTGA has hosted OBIS
139   training workshops to train data providers on how to prepare, standardize, and submit their data to
140   OBIS, where their data is cited and safely secured. Organisations such as OTGA need to be
141   financially supported by governments in order to actively educate and train data keepers and
142   encourage them to share their data with the global community. However, as the scientific
143   community is relatively small and financial sources for training are limited, the future of large-
144   scale biodiversity studies is likely to rely on the well-designed application of citizen science in
145   addition to technological advances (Stuart-Smith et al. 2017; Thiel et al. 2014).

146   **3. Promoting synergy of biodiversity research efforts via increased collaboration at all**
147   **levels.**

148

149   In order to predict and discover biodiversity on a global scale, collaborative approaches among
150   institutions and nations are necessary. Guralnick *et al.* (2007) proposed a framework to use online
151   databases and tools to improve and standardize geographic data, and to validate and highlight
152   taxonomic data and misidentifications. They also suggested that a global infrastructure for web-
153   based tools would enhance the quality of visualizing and standardizing raw biodiversity data and
154   lead to a higher degree of collaboration and accessibility of knowledge (Guralnick et al. 2007).
155   The decade long Census of Marine Life was the largest global collaboration amongst
156   marine biologists (O'Dor et al. 2012). Its legacy continues in OBIS with regard to data publication,
157   but also continued international collaboration amongst polar, deep-sea and other researchers. The

158 International Association for Biological Oceanography (IABO) is the organisation officially
159 responsible for coordinating the marine biodiversity community (Costello et al. 2015a). It runs the
160 MARINE-B email list with over 1,000 subscribers, and holds a World Conference on Marine
161 Biodiversity every three years. Many others, often more specialist-focused, conferences also serve
162 to bring marine biodiversity researchers together. These serve to make introductions and help build
163 collaborative relationships among researchers. However, most research funding is for topics of
164 national rather than international importance. For example, not every country will have specialist
165 expertise in every taxonomic group. Thus, sharing of taxonomic expertise can alleviate funding
166 deficits, allow the transfer of knowledge, and lead to international partnerships.
167 The number of marine species formally described each year has never been greater, and
168 aside from naming these species, more work is required to understand their life histories and
169 ecology, biogeography, and evolution (Appeltans et al. 2012a; Appeltans et al. 2012b). Costello et
170 al. (2015b) recommended the use of collaborative online databases, taxonomic effort improved
171 and increased through communication, easier access to specimens, engagement of non-specialists,
172 and international collaboration (Costello et al. 2015b). Further, Costello *et al.* (2013c) advocated
173 abandoning "data-sharing" and instead suggested requiring data publication within a journal or to
174 online infrastructures such as OBIS, WoRMS, and/or the Global Biodiversity Information Facility
175 (GBIF) (Costello et al. 2013c). A fundamental aspect of Aichi Target 19, namely discovering the
176 full extent of biodiversity in the world's oceans, is not possible without international collaboration.
177
178 **4. Utilization and promotion of taxonomic expertise and species identification tools to**
179 **better recognize and catalogue biodiversity.**
180
181 "Good" taxonomy is an absolute necessity for biodiversity recognition and management (Thomson
182 et al. 2018). It is very important to pass on the knowledge of experienced taxonomists to others.
183 In this regard, field-specific training workshops can be of great importance. As an example, two
184 'IceAGE (Icelandic marine Animals: Genetics and Ecology) amphipod identification workshops'
185 were recently held, consisting of two weeks of work of a group of taxonomists accompanied by
186 students. This resulted in the identification of more than 20,000 amphipod specimens, and the
187 publication of seven research papers dealing with the taxonomy, diversity and ecology of this
188 group around Iceland (Brix et al. 2018).
189 Another problem in recognizing biodiversity is the complexity of access to information and
190 images that can help end-users in identifying the organisms collected in their samples. To solve
191 this requires comprehensive online identification guides to all species on Earth (Costello et al.
192 2013b). It is surprising that despite the numerous online digital initiatives regarding biodiversity
193 resources for this most practical need (how to identify species) lack leadership and remain scarce.
194 Targeted funding to support such resources is urgently needed to help the wider community
195 identify species quickly and accurately, including species that may be invasive or pathogenic.
196 Despite great publicity and interest, publically available DNA libraries, such as the Barcode of
197 Life (Ratnasingham & Hebert 2007), are still far from having complete coverage of the Tree of

198   Life. Moreover, DNA is often only useful if the species has already been formally described,
199   specimens from which DNA has been sampled have been correctly identified, and the DNA
200   sequence(s) published in an open access database. Other tools that can help in species identification
201   for conservation and resource management include interactive keys. Unfortunately, there are only
202   such keys for a few marine taxa, and these mostly concern higher taxonomic levels (family-level
203   or higher) (Dallwitz 2006; Nimbs 2017).
204   Along with Aichi Target 19, the exchange of knowledge between experienced scientists
205   and young researchers as well as the use of different identification tools (e.g. interactive keys,
206   barcode databases) will help in biodiversity recognition. These targets need to be prioritised by
207   governments and funding agencies as they are fundamental to quality assurance in other areas of
208   biology, ecology, and resource management.
209
210   **5. Improvement and standardization of genetic, genomic, and other "omics" tools to aid in**
211   **discovery, assessment, description, and cataloging of biodiversity.**
212
213   Countless studies have used genomic tools to study marine biodiversity, connectivity, and
214   functional diversity (Carvalho et al. 2010). While data sharing, standardized sampling, metadata
215   collection, and sequencing protocols still require significant standardization, the use of repositories
216   such as GenBank, Dryad, and Sequence Read Archive have made published data much more
217   accessible. We expect this trend to continue as new tools, such as the Genomic Observatories
218   Metadata database (GeOMe), streamline sequencing data and metadata submission (Deck et al.
219   2017).
220   The classification and phylogeny of eukaryotic organisms benefits from the use of genetic
221   markers that help delineate species in combination with morphological, ecological, and/or
222   physiological information (Hebert et al. 2003). Currently, no uniform threshold value has been
223   established for species delineation, and there is no single "universal" DNA barcode that captures
224   all eukaryotic life. Even within a single animal order there can be large differences in this value
225   between families (Tempestini et al. 2018). Despite these issues, DNA barcoding and next-
226   generation metabarcoding can reveal genetic diversity and are useful tools for the description and
227   cataloguing of biodiversity.
228   Modern high-throughput sequencing (HTS) technologies have advanced DNA barcoding
229   methods by producing millions of individual sequences per analyzed sample, enabling DNA
230   metabarcoding from environmental DNA (eDNA) and complex community mixtures. Community
231   and environmental metabarcoding are both useful tools to discover cryptic (undetected until
232   genetic analyses) diversity in the marine realm, and assess ocean biodiversity in a non-invasive
233   and high-throughput manner (Goodwin et al. 2017).
234   In order to obtain robust and reproducible metabarcoding results, critical methodological
235   aspects remain to be improved (Dickie et al. 2018; Goldberg et al. 2016; Nichols et al. 2018).
236   Studies are needed to address the effects of alternative protocols on sampling, molecular, and
237   bioinformatic processing level in order to develop standardized and reliable techniques for

238 applying these new methods. Furthermore, because large amounts of marine organisms have not
239 been genetically characterized, integrative approaches should be supported in order to fill database
240 gaps. The continued improvement and standardization of genetic, genomic, and other "-omics"
241 tools (e.g. proteomics, transcriptomics) will continue to be valuable components in the discovery
242 of new marine prokaryotes and eukaryotes, as well as in monitoring biodiversity, thereby
243 contributing to Aichi Target 19.

244

245 **6. Identifying biodiversity and biogeographic knowledge gaps and promoting efforts to**
246 **reduce such gaps.**

247

248 Deep-sea ecosystems include about 65% of the world's surface but are far less studied and sampled
249 than shallower depths (Costello et al. 2018; Costello et al. 2010). Although deep-sea studies have
250 increased rapidly in recent decades, there are large gaps in global sampling coverage, for example
251 in the Indian and Pacific Oceans, and major efforts are needed to continue to be directed into
252 offshore research (Saeedi et al. 2019). The distribution and diversity of deep-sea fauna thus still
253 remains poorly-known due to the size and remoteness of deep-sea ecosystems. For example, recent
254 studies have shown that the global latitudinal marine species richness gradient follows a bi-modal
255 pattern related to temperature and habitat availability (Chaudhary et al. 2016a; Chaudhary et al.
256 2017; Saeedi et al. 2017a; Saeedi & Costello 2019a; Saeedi & Costello 2019b; Saeedi et al. 2017b).
257 This finding is supported by the fossil record, which shows reduced species richness at the equator
258 in warm periods (Kiessling & Aberhan 2007). As such, the peaks in this bimodal distribution may
259 become further separated under future climate change and ocean warming. However, there is still
260 no consensus about this bimodal pattern in the deep sea, where food supply may be more important
261 than temperature in defining species distribution. For example, Woolley *et al.* (2016) examined
262 165,000 distribution records of Ophiuroidea and revealed that biogeographic patterns in species
263 richness in the deep sea are associated with chemical energy and proximity to slope habitats.
264 However, these patterns require investigation in other taxa, from micro- to mega-fauna, epi-fauna
265 and infauna (Woolley et al. 2016).
266   One issue in studying present and future global deep-sea biodiversity patterns are the few
267 publicly available distribution records and environmental data. Deep-sea expeditions began over
268 100 years ago, but distribution data are often still retained in inaccessible archives, sometimes in
269 local languages of that country, and are not publically available to the global community.
270 Additionally, acquisition of data describing the distributions of deep-sea species is often limited
271 by prohibitive costs and logistical difficulties in surveying the deep ocean. Environmental
272 suitability modeling has thus become a cost-effective tool for identifying potential locations of
273 deep-sea species, particularly for areas that have never been explored (Assis et al. 2018; Basher &
274 Costello 2016; Danovaro et al. 2017; Serrano et al. 2017).
275   Understanding how abiotic drivers influence species distributions can contribute to filling
276 spatial gaps of biodiversity hotspots and endangered areas (McHenry et al. 2017; Saeedi et al.
277 2017a; Saeedi & Costello 2019a; Saeedi & Costello 2019b; Saeedi et al. 2017b). Since some of

278   these drivers can be observed by satellite imagery, it is possible to model some community
279   assemblages in difficult-to-access locations. The development of models of species richness and
280   cumulative anthropogenic impact distributions could be useful for conservation purposes and/or
281   other spatial planning applications (Selig et al. 2014). Costello et al. (2018) proposed that sampling
282   of the oceans should be stratified in relation to environmental variability, with more variable
283   environments receiving more sampling focus in space and time (Costello et al. 2018). Coupled
284   with a recent objective (data driven) delineation of marine biodiversity into 30 biogeographic
285   realms based on the endemicities of marine plants and animals (Costello et al. 2018; Costello et
286   al. 2010; Costello et al. 2015b), this provides a framework for more representative sampling of the
287   oceans. These realms include 18 continental-shelf and 12 offshore realms, including unique seas,
288   such as the Baltic and Black seas, and subdivisions of the Indian, Atlantic, and Pacific oceans, and
289   polar waters. These are broad scale patterns, and application of stratified sampling at local levels
290   requires finer spatial resolution data; such as benthic habitat maps and observations of movements
291   of threatened species to know where they occur.
292
293   **7. Control of anthropogenic pressures on vulnerable ecosystems impacted by climate**
294   **change or ocean acidification to maintain their integrity and functioning.**
295
296   Fisheries and marine mammal hunting have had large impacts on biodiversity at local scales for
297   centuries, and at global scales for the past two centuries (Pauly et al. 2002). Clearly fishery
298   management measures struggle to prevent overfishing, and trawling that destroys seabed habitats
299   is widely permitted, while bycatch of seabirds, turtles and marine mammals is pushing some
300   species to extinction (McCauley et al. 2015). Progress in reducing bycatch is compromising
301   reaching the achievement of Aichi Target 12 related to preventing species extinctions. A proven
302   solution to reversing some negative trajectories are marine reserves (no-take MPAs) (Costello
303   2014). However, about two-thirds of coastal countries lack even one marine reserve, and over 90%
304   of MPAs allow fishing and thus prevent the recovery of biodiversity to natural conditions (Costello
305   & Ballantine 2015). This failure to conserve and help fisheries recover, despite the potential
306   benefits of MPAs to nature, education, science (they act as controls for effects of fishing outside
307   them), tourism, and fish populations defies what is best for society. With less than 3% of the ocean
308   in reserves, there seems little hope that Aichi Target 11's goal of 10% of the oceans being protected
309   in MPAs by 2020 will be reached. In addition, there appears to be negligible progress towards
310   more sustainable use of the oceans, as called for in Targets 4, 6 and 7. Target 3, the reduction of
311   harmful subsidies, has also seen little progress and too many fisheries still receive indirect and/or
312   direct subsidies from governments that enable further unsustainable overfishing.
313   Aichi Target 10 calls for reduced anthropogenic impacts on coral reefs. Coral reefs suffered
314   global-scale bleaching events in 2015-2017, even within MPAs, resulting in massive damage to
315   these ecosystems, including mass mortality of hermatypic corals and other zooxanthellate
316   organisms (Hughes et al. 2017), and associated reduced ecosystem functioning (Hughes et al.
317   2018a; Hughes et al. 2018b). Additionally, such events have economic effects such as reduced

318   tourism (Prideaux et al. 2017). Overall, the trajectory of coral reefs continues to be one of
319   downward degradation in the face of increasing anthropogenic pressures, including climate change
320   and continued exploitation (Heery et al. 2018).
321   Other anthropogenic impacts on marine biodiversity include excess nutrient input, oxygen
322   depletion, and invasive species. Levels of these impacts are to be reduced and their management
323   improved as part of Aichi Targets 8 and 9. Progress in management of introduced and invasive
324   marine species has been made with the establishment of the World Register of Introduced Marine
325   Species (WRiMS) (Ahyong 2018). Because of the nature of invasive species, management of their
326   information is most cost-effectively done at a global rather than local scale. The next steps should
327   include access to species identification resources and a dynamic online reporting and early warning
328   system.
329   Both global warming and ocean acidification are closely linked with the anthropogenic
330   input of CO_2 and other greenhouse gases into the atmosphere, and without controlling these issues,
331   the future of coral reefs looks bleak (IPCC 2018). Minimizing anthropogenic impacts such as
332   increased runoff from coastal development and reducing overfishing can help delay the
333   degradation of coral reef ecosystems, but it is estimated more than half of all coral reefs now
334   experience medium to high anthropogenic pressures (Halpern et al. 2008) and the extirpation of
335   species from many coral reefs due to climate change is predicted (Molinos et al. 2016).
336   There are some success stories, such as Palau, which has passed stringent legislation
337   protecting coral reef diversity, including the world's first no-take zone for sharks (Vianna et al.
338   2012), stringent legal protection (Gouezo et al. 2017), and a visitor's pledge and public awareness
339   campaign (https://palaupledge.com/). Other regions or countries following the lead of these
340   exemplars could help buy time for coral reef ecosystems. For instance, the Australian government
341   implemented the Great Barrier Reef (GBR) Zoning Plan 2003 in 2004, which set aside one-third
342   of the GBR as a no-take zone (McCook et al. 2010). This resulted in a significantly lower
343   proportion of reefs being affected by Crown-of-thorns starfish outbreaks in no-take zones than in
344   fished zones (McCook et al. 2010), but the trajectory of GBR coral reef ecosystems remains bleak
345   due to warming-associated coral bleaching (Hughes et al. 2018a; Hughes et al. 2018b).
346
347   **Conclusions**
348   While there has been considerable progress in addressing many of the priorities of the Aichi
349   Targets, including the development and application of biodiversity tools and higher standards, as
350   well as increased educational activity and increasing standardization of genetic and genomic tools,
351   progress towards sustainable use is very limited (Table 1). Of the seven priorities for marine
352   biodiversity to achieve the Achi Targets we reviewed here, we judged six have seen some progress.
353   However, other goals such as reducing anthropogenic stressors on vulnerable ecosystems have
354   clearly not been met and seem certain to fall short of the 2020 Targets, as previously concluded
355   (Tittensor et al. 2014). We recommend continued efforts regarding international cooperation in
356   marine biodiversity informatics to increase efficiencies of data management and accessibility,
357   paralleled by field observations stratified by environmental conditions and societal needs,

358 synergised by online access to taxonomic information and species identification guides, and
359 research into more cost-efficient methods for field sampling that minimise impacts on biodiversity
360 (e.g. sensors, video, eDNA). This surveillance of marine biodiversity should occur in areas where
361 human impacts, particularly fishing, occur, but also in fully-protected Marine Protected Areas
362 where no fishing occurs (i.e., marine reserves). The lack of progress towards establishing the latter
363 reference areas compromises our understanding of natural conditions and how to judge the
364 sustainability of human activities in the ocean and their impacts on marine biodiversity.
365

366 **Acknowledgements**
367 We would like to thank David Beauchesne, Rémi M. Daigle, Jésica Goldsmit, Philippe
368 Archambault, Anna Metaxas, and Paul Snelgrove for their thoughts and leadership of the
369 mentorship program organizing committee and workshop facilitators. Special thanks also to Rémi
370 M. Daigle and Jésica Goldsmit for reviewing the current paper. Comments from Martin Thiel and
371 Naomi Kingston greatly improved an earlier version of this paper.

The examined Aichi Targets

Table 1. The Aichi Targets examined in this study and their relationship to the scientific priorities identified by participants of the 2018 World Conference on Marine Biodiversity. The Targets were grouped into Strategic Goals by the Convention on Biological Diversity. * negligible progress, ** notable progress, *** good progress.

Aichi Target	Scientific Priority	Progress
	Developing, improving and enhancing biodiversity data standards, exchange, and analytical tools, via standardized techniques.	***
	Educational activities to increase data mobilisation by taxonomists, data users, and/or wider audiences.	***
Strategic Goal E: Enhance implementation through participatory planning, knowledge management and capacity building	Promoting synergy of biodiversity research efforts via increased collaboration at all levels.	***
Target 19 By 2020, knowledge, the science base and technologies relating to biodiversity, its values, functioning, status and trends, and the consequences of its loss, are improved, widely shared and transferred, and applied.	Utilization and promotion of taxonomic expertise and species identification tools to better recognize and catalogue biodiversity.	**
	Improvement and standardization of genetic, genomic, and other "omics" tools to aid in discovery, assessment, description, and cataloging of biodiversity.	**
	Identifying biodiversity and biogeographic knowledge gaps and promoting efforts to reduce such gaps.	***
Strategic Goals A: Address the underlying causes of biodiversity loss by mainstreaming biodiversity across government and society [1] B: Reduce the direct pressures on biodiversity and promote sustainable use, Targets 6 to 10 [2] and C: To improve the status of biodiversity by safeguarding ecosystems, species and genetic diversity, Targets 11-13 [3]	Control of anthropogenic pressures on vulnerable ecosystems impacted by climate change or ocean acidification to maintain their integrity and functioning.	*

3 [1] **Target 3:** By 2020, at the latest, incentives, including subsidies, harmful to biodiversity are eliminated, phased
4 out or reformed in order to minimize or avoid negative impacts, and positive incentives for the conservation and
5 sustainable use of biodiversity are developed and applied, consistent and in harmony with the Convention and other
6 relevant international obligations, taking into account national socio economic conditions. **Target 4:** By 2020, at the
7 latest, Governments, business and stakeholders at all levels have taken steps to achieve or have implemented plans
8 for sustainable production and consumption and have kept the impacts of use of natural resources well within safe
9 ecological limits.
10 [2] **Target 6:** By 2020 all fish and invertebrate stocks and aquatic plants are managed and harvested sustainably,
11 legally and applying ecosystem-based approaches, so that overfishing is avoided, recovery plans and measures are in
12 place for all depleted species, fisheries have no significant adverse impacts on threatened species and vulnerable
13 ecosystems and the impacts of fisheries on stocks, species and ecosystems are within safe ecological limits. **Target**
14 **7:** By 2020 areas under agriculture, aquaculture and forestry are managed sustainably, ensuring conservation of
15 biodiversity. **Target 8:** By 2020, pollution, including from excess nutrients, has been brought to levels that are not
16 detrimental to ecosystem function and biodiversity. **Target 9:** By 2020, invasive alien species and pathways are
17 identified and prioritized, priority species are controlled or eradicated, and measures are in place to manage

18 pathways to prevent their introduction and establishment. **Target 10:** By 2015, the multiple anthropogenic pressures
19 on coral reefs, and other vulnerable ecosystems impacted by climate change or ocean acidification are minimized, so
20 as to maintain their integrity and functioning.
21 **[3] Target 11:** By 2020, at least 17 per cent of terrestrial and inland water, and 10 per cent of coastal and marine
22 areas, especially areas of particular importance for biodiversity and ecosystem services, are conserved through
23 effectively and equitably managed, ecologically representative and well-connected systems of protected areas and
24 other effective area-based conservation measures and integrated into the wider landscapes and seascapes. **Target 12:**
25 By 2020 the extinction of known threatened species has been prevented and their conservation status, particularly of
26 those most in decline, has been improved and sustained. **Target 13:** By 2020, the genetic diversity of cultivated
27 plants and farmed and domesticated animals and of wild relatives, including other socio-economically as well as
28 culturally valuable species, is maintained, and strategies have been developed and implemented for minimizing
29 genetic erosion and safeguarding their genetic diversity.
