Osteoarthritis (OA) is the most common motor system disease in aging people, characterized by matrix degradation, chondrocyte death, and osteophyte formation. OA etiology is unclear, but long noncoding RNAs (lncRNAs) that participate in numerous pathological and physiological processes may be key regulators in the onset and development of OA. Because profiling of lncRNAs and their biological function in OA is not understood, we measured lncRNA and mRNA expression profiles using high-throughput microarray to study human knee OA. We identified 2,042 lncRNAs and 2,011 mRNAs that were significantly differentially expressed in OA compared to non-OA tissue (>2.0 - or <-2.0 -fold change; $p < 0.5$), including 1,137 lncRNAs that were upregulated and 905 lncRNAs that were downregulated. Also, 1,386 mRNA were upregulated and 625 mRNAs were downregulated. QPCR was used to validate chip results. Gene Ontology analysis and the Kyoto Encyclopedia of Genes and Genomes was used to study the biological function enrichment of differentially expressed mRNA . Additionally, coding-non-coding gene co-expression (CNC) network construction was performed to explore the relevance of dysregulated lncRNAs and mRNAs. Finally, the gain/loss of function experiments of Inc-SAMD14-4 was implemented in IL-1 β -treated human chondrocytes. In genel, this study provides a preliminary database for further exploring lncRNA-related mechanisms in OA.

ABSTRACT

Background

Osteoarthritis (OA) is the most common motor system disease in aging people, characterized by matrix degradation, chondrocyte death, and osteophyte formation. OA etiology is unclear, but long noncoding RNAs (lncRNAs) that participate in numerous pathological and physiological processes may be key regulators in the onset and development of OA. Because profiling of lncRNAs and their biological function in OA is not understood. Here we report a new lncRNA-lnc-SAMD14-4 and explored its role and potential ability in osteoarthritis development.

Methods

The human cartilage tissues were obtained from patients. lncRNA and mRNA expression profiles were analyzed using the Affymetrix human lncRNA chips. Gene ontology (GO) enrichment and KEGG pathway analysis of mRNAs were conducted to identify the related biological modules and pathologic pathways. The co-expression analysis was used to predict the interaction between the lncRNA-mRNA couple associated with PI3K-Akt pathway. Real-time PCR was conducted to validate the expression pattern of lncRNA and mRNA. The gain/loss of function experiments of lnc-SAMD14-4 was implemented in IL-1 β -treated human chondrocytes to explore its role in osteoarthritis.

Results

(1) In this study, total 2042 lncRNAs were detected significantly different expression in OA compared to non-OA tissue. Total 2011 mRNA was detected significantly different expression in OA compared to non-OA tissue. (2) GO analysis was used to investigate the effect of all differentially expressed gene on pathogenesis of OA. (3) 27 pathways corresponded to up-regulated mRNAs and 94 pathways corresponded to down-regulated mRNAs were determined by KEGG pathway analysis. (4) The result of qRT-PCR was consistent with microarray profiling

47 analysis. (5)The lnc-SAMD14-4 mediated *COL1A1* and *COL1A2* expression in IL-1 β -treated human chondrocytes.

48 **Discussion**

49 This study provides a preliminary database for further exploring lncRNA-related mechanisms in OA. The study also
50 revealed that lnc-SAMD14-4 may perform a significant role in the development of osteoarthritis.

51

Introduction

Osteoarthritis (OA) is common in aging populations and is a global health burden [1, 2]. OA arises from cartilage matrix degradation, chondrocyte death, and osteophyte formation[3, 4]. The pathology of OA is fairly well understood, and multiple therapies exist, from corticosteroids and nonsteroidal anti-inflammatory drugs to treat symptoms [5, 6], experimental stem cell therapies to treat specific forms of OA, and biologics to address specific inflammatory mediators such as cytokines. OA may also be treated with joint replacement surgery, and this is common in the elderly. Even so, better drugs are always desired.

Recently, gene regulation functions of long non-coding ribonucleic acids (lncRNAs) in OA have been studied. LncRNAs are non-protein-coding transcripts (>200 nucleotides) that participate in numerous pathological and physiological processes[7-9]. Some lncRNAs have been defined as key regulators of the onset and development of OA[10-15]. For instance, overexpression of HOTAIR may cause OA by inducing chondrocyte apoptosis[10, 16]. Fu's group used microarray and bioinformatics to identify 4,714 differentially expressed lncRNA in non-OA cartilage compared to knee OA patients[17]. Liu's group used microarray to identify 153 lncRNAs differently expressed in OA and designated a specific lncRNA CIR to have an important function in degradation of the chondrocyte matrix[14]. Differences in lncRNA expression links with physiological processes often arise between laboratories which use high-throughput screening, and therefore, data about lncRNA in the pathogenesis of OA is needed to reach consensus about which contribute to OA. To address this, we measured differentially expressed lncRNAs and mRNAs using high-throughput microarray to study human knee OA and compared these data to non-OA samples.

Materials and methods

Specimen collection

A Kellgren-Lawrence (KL) system was used to measure OA severity [18]. OA cartilage (KL grades 3 or 4) were collected from 19 patients undergoing total knee joint replacement due to severe OA, and normal cartilage (KL grades 0) were collected from 11 patients (trauma, *thromboangiitis obliterans*, or osteosarcoma, or limb amputation) without history of rheumatoid arthritis or OA. Informed consent was signed by all patients and additional informed consent was obtained for publication of subject age and sex. This study was approved by the Ethics commission of the 163rd Central Hospital of the Chinese People's Liberation Army (IRB. [2015] 001). Patient data appear in Supplementary Table 1. Clinical specimens were divided for QPCR and for array analyses.

lncRNA and mRNA microarray analysis

Quality tests, sample labeling, and hybridization to human WT lncRNA microarray (Affymetrix) were conducted by Oebiotech Co (Shanghai, China) (Supplement Figure 1), their detailed definition can be found at [19, 20], The Genechip included 63,542 non-coding and 27,134 coding transcripts. Images were taken with an Affymetrix Scanner3000, and data normalization and probe filtering were conducted using an Affymetrix GeneChip Expression Console (version 4.0, Affymetrix). lncRNA-mRNA expression between OA and non-OA groups was identified as a ≥ 2.0 fold-change (FC) for up-regulation or a ≤ -2.0 fold-change for down-regulation and $p \leq 0.05$. Afterwards, the GO and KEGG analyses were used to identify roles of differentially expressed mRNAs with respect to GO terms or pathways. Their detailed definition can be found at [21, 22]. Then, a Volcano plot and hierarchical clustering were used to show distinctions in gene expression patterns among samples. Finally, a coding-non-coding gene co-expression (CNC) network was drawn using Cytoscape software.

The microarray data are available through the GEO database with accession number GSE113825.

RNA extraction and quantitative PCR

An RNeasy Lipid Tissue Mini Kit (Qiagen, Germany) was used to extract total RNA according to kit directions. A NanoDrop ND-1000 spectrophotometer was used to measure RNA quality and purity. SDS-PAGE was used to measure RNA integrity. Total RNA from samples was reverse transcribed into cDNA using an All-in-one First-Strand cDNA Synthesis Kit (GeneCopoeia Inc, Rockville, MD) according to the user manual. QPCR primers were designed and synthesized at the Shanghai Sangon Company (Supplementary Table 2). qPCR was conducted using AceQ qPCR SYBR Green Master Mix (Vazyme Biotech Co, China) on a Bio-Rad CFX Connect™ Real-Time PCR detection system (Bio-Rad Germany). Furthermore, qPCR was performed according to the manual and included 10 µl SYBR Master Mix, 0.4 µl forward primer (10 µM), 0.4 µl reverse primer (10 µM), 0.4 µl ROX Reference Dye 1, 2 µl cDNA, and 6.8 µl MiliQ water. The qPCR reaction conditions were pre-denaturation at 95 °C for 5 min, followed by 95 °C for 10 sec, and 60 °C for 30 sec for 40 cycles, and a final extension at 95 °C for 15 sec, 60 °C for 60 sec, and 95 °C for 15 sec. The $2^{-\Delta\Delta C_t}$ method was used to assess gene expression as previous study[23]. Each experiment was conducted in triplicates.

Cell culture and treatment

Human primary chondrocytes were available from CHI Scientific, Inc(China). The cells were incubated into DMEM(Gibco, USA) medium supplemented with 14% FBS(Gibco, USA). The culture was cultivated at 37°C in a 5% CO₂ incubator and the medium was changed every 3 days. All study were conducted using primary chondrocytes from passages 1-4. Cells were treated without or with 10 ng/ml human recombinant interleukin-1 beta(IL-1β)(Sigma-Aldrich, St Louis, MO, Germany) for 12h, 24h and 48h.

Cell transfection

The overexpression vectors of lnc-SAMD14-4(pcDNA3.1⁺- lnc-SAMD14-4) and blank vector

pcDNA3.1(pcDNA3.1⁺- vector) were transfected to human primary chondrocytes using Lipofectamine 3000(Invitrogen, USA). Three independent specifically targeting siRNA, including si-lnc-SAMD14-4(1#, 2# and 3#), and control siRNA were designed and purchased from Ribo Biotechnology Co. Ltd.(GuangDong, China). These siRNA were transfected to human primary chondrocytes to conduct gain/loss of function of lnc-SAMD14-4.

Statistical analysis

Differences in expression of lncRNA-mRNA between OA and non-OA groups was assessed with a Student's *t* test. GO and KEGG pathways were assessed using Fisher's exact test. Other data were analyzed using one-way ANOVA and multiple groups were compared using Bonferroni's method. GraphPad Prism 6.0 (GraphPad Software San Diego,CA) was applied for data analysis and drawing. Data are shown as means \pm SD, and $p < 0.05$ was regarded to be statistically significant.

Results

Analysis of differentially expression lncRNAs-mRNAs in OA

We found 2,042 lncRNAs significantly differently expressed in OA compared to non-OA tissue and these data appear in Supplementary Table 3. The most upregulated lncRNA was lnc-SAMD14-4 and the most downregulated lncRNA was lnc-MSMP-2. The top 15 most dysregulated(down or up) lncRNAs are listed in Table 1.

Data for mRNA expression in OA revealed 2,011 mRNAs were dysregulated in OA compared to non-OA cartilage tissue and 1,386 mRNA were upregulated and 625 mRNAs were downregulated (Supplementary Table 4). Among these mRNAs, MMP-13 was the most up-regulated protein coding RNA, and this regulated articular cartilage degradation[24]. MYOC was the most strongly down-regulated and the top 15 up-regulated or down-regulated mRNAs appear in Table 2. Data for differentially expressed genes (including lncRNA and mRNA) appear in Fig. 1A-C.

Gene Ontology (GO) analysis and Kyoto Encyclopedia of Genes and Genomes (KEGG) analysis of dysregulated mRNAs

The most enriched GOs targeted by up-regulated mRNAs were extracellular matrix organization (GO:0030198), extracellular exosome (GO:0070062), and collagen binding (GO:0005518) in biological process, cellular process, and molecular function (Fig. 2A-C, Supplementary Table 5-7). Protein stabilization (GO:0050821), cilium (GO:0005929), and heparan sulfate proteoglycan binding (GO:0043395) were the most enriched GOs associated with down-regulated transcripts (Fig. 2D-F, Supplementary Table 8-10).

We identified 27 pathways with up-regulated mRNAs and the enriched pathway was cytochrome P450 (Supplementary Table 11). Then, 94 pathways corresponded to down-regulated mRNAs according to KEGG pathway analysis and the top enriched pathway was focal adhesion (Supplementary Table 12). The top 20 pathways targeted with down-regulated and up-regulated transcripts appear in Fig 3A and B.

LncRNA-mRNA co-expression network

The co-expression networks are of biological interest since co-expressed genes are controlled by the same transcriptional regulatory program, functionally related, or members of the same pathway or protein complex[25, 26]. We and others confirmed that apoptosis was involved in OA pathogenesis [27-30], and that the PI3K-Akt signaling pathway was important for apoptosis[31]. Since we found 74 dysregulated mRNAs enriched in the PI3K-Akt signaling pathway (Supplementary Table 13), we analyzed these dysregulated mRNA and identified 1,974 correlations for lncRNA-mRNA interaction pairs that satisfy $p < 0.01$ and Pearson correlation coefficients > 0.95 . (Supplementary Table 14). Then, the top 500 of 1,974 lncRNA-mRNA pairs were used to draw the network (Supplementary Table 15). These 500 lncRNA-mRNA pairs including 57 mRNA and 363 lncRNA, and 362 pairs had a positive association; the rest were negatively associated. The co-expression network showed that one lncRNA

correlates with many mRNAs and vice versa (Fig. 4). Some lncRNA-mRNA pairs included the most dysregulated mRNA and lncRNA. For example, *COL1A1* (mRNA, FC=175.43033) and *COL1A2* (mRNA, FC=85.32694) were strongly associated with lnc-SAMD14-4 (lncRNA, FC= 86.11047). besides, all the lncRNA-mRNA co-expressed pairs with Pearson correlation coefficients>0.98

Verification of lncRNAs and mRNAs expression by qRT-PCR

To confirm microarray profiling analysis, four lncRNAs (lnc-SAMD14-4, lnc-MARCKS-7, lnc-MSMP-2 and lnc-NPVF-4) and four mRNAs (*SERPINF1*, *COL1A1*, *MYOC* and *PAK3*) were selected and measured using qRT-PCR for 53 clinical specimens (34 OA and 19 normal specimens). Data for qRT-PCR agree with chip profiling analysis (Fig. 5).

Prediction of novel lncRNAs targeting

In this study, we selected the most dysregulated lncRNA (lnc-SAMD14-4) as the potential lncRNA for function research. To analysis the gene coding-potential of lnc-SAMD14-4, the open-reading frames(ORFs) and codon-substitution frequency(CSF) were measured according to the former research[14, 32]. The ORF Finder(National Center for Biotechnology Information) fail to predict a ORFs of more than 300nt. Furthermore, we Blasted all the positive-sense strand ORFs, which is marked by “+” in the figure, and no highly homologous protein was found among those short peptide(Supplement Figure 2). On the other hand, the PhyloCSF analysis of lnc-SAMD14-4 was negative(Supplement Figure 3). These all revealed that lnc-SAMD14-4 have no potential to encode any functional protein product.

COL1A1, COL1A2 and lnc-SAMD14-4 were highly expressed in the IL-1 β -treated human primary chondrocytes.

According our co-expression network analysis, COL1A1 and COL1A2 were strongly associated with lnc-

SAMD14-4. Thus we speculated that lnc-SAMD14-4 may contribute to the osteoarthritis by interacting with COL1A1 and COL1A2. IL-1 β -treated human primary chondrocytes was used to fit the process of human osteoarthritis in the previous study[17, 33]. The expression levels of *COL1A1*, *COL1A2* and lnc-SAMD14-4 were examined by QPCR in the IL-1 β -treated human chondrocytes, we found that *COL1A1* and *COL1A2* were upregulation after IL-1 β -treated for 24h and 48h. Furthermore, lnc-SAMD14-4 were also upregulation by IL-1 β in time-dependent(Fig. 6). These results demonstrate that there seemed to be a positive correlation between lnc-SAMD14-4 and COL1A1, COL1A2 expression induced by IL-1 β . Hence, the human primary chondrocytes were treated with or without IL-1 β for 48h in the follow-up experiments.

lnc-SAMD14-4 was involved in IL-1 β -induced COL1A1 and COL1A2 expression in the human primary chondrocytes.

For further discussing the function of lnc-SAMD14-4 in the IL-1 β -induced *COL1A1* and *COL1A2* activities. We performed gain/loss of function experiments. As shown in Figure 7A, lnc-SAMD14-4 overexpression promotes the expression of *COL1A1* and *COL1A2* in the human primary chondrocytes with or without IL-1 β -treated(p<0.05).

To explore the knockdown effects of lnc-SAMD14-4 on *COL1A1* and *COL1A2*. We designed and transfected three independent si-lnc-SAMD14-4(1#, 2# and 3#) in human primary chondrocytes. The strongest silencing effects were observed in si-lnc-SAMD14-4(2#) and it's used for subsequent experiments(Data were not show). The knockdown of lnc-SAMD14-4 significantly decreased the expression of *COL1A1* and *COL1A2* (Figure 7B). These data revealed an important lncRNA may closely relate to the COL1A1 and COL1A2 expression in osteoarthritis.

Discussion

To our knowledge, there has been some study that focuses on the lncRNA expression profiles in the osteoarthritis, for instance, Fu's group identified 4,714 lncRNAs and Liu's group identified 152 lncRNAs that were differentially

expressed in OA cartilage compared with controls. Pearson's group further identified lncRNAs related to the inflammatory response in human hip OA cartilage using primary chondrocytes isolated from hip articular cartilage and IL-1 β induction to simulate OA. But the roles of lncRNAs in osteoarthritis were far from full understood and we think it's essential to get more data about the role of lncRNA in OA

In the present study, We measured expression profiles lncRNAs and mRNAs using high-throughput microarray and bioinformatics to study human knee OA and compared this to non-OA tissue by set a standards filter of $FC \geq 2.0$, $p < 0.05$; Because our work used Affymetrix and previous studies used Arraystar, which are different platforms, comparing lncRNA data is problematic.

Using these chips, we identified 2,042 dysregulated lncRNAs and 2,011 differentially expressed mRNAs in OA samples compared to non-OA tissues, including *COL1A1*, *COL1A2*, *MMP-13*, *MMP-9*, and *TNFAIP6*, which are associated with cartilage biology and OA. Studies with the top 4 dysregulated lncRNAs and mRNAs, except for *MMP13* mRNA which has already been proved to be related to the chondrocyte biological processes or osteoarthritis[34-38], verified that qRT-PCR data for 53 specimens (34 OA and 19 normal specimens) were consistent with chip analysis.

Next, GO analysis and pathway analysis were used to study biological function enrichment of differentially expressed mRNA as described above. For instance, the most enriched GOs targeted by up-regulated mRNAs were extracellular matrix organization (GO:0030198), extracellular exosome (GO:0070062), and collagen binding (GO:0005518) in biological processes, cellular processes, and molecular function. Functions of the extracellular matrix and collagen binding have been accepted to be important to the onset and progression of OA [39, 40].

A lncRNA-mRNA co-expression network was built to identify associations between lncRNA and mRNA. The fundamentals of co-expression network analysis is that if the expression pattern of mRNAs and lncRNAs shows

an opposite or identical correlativity to the other, it is possible that there are some interaction between the lncRNA-mRNA. We noticed that some most dysregulation lncRNA or mRNA made a lncRNA-mRNA pairs, among these, lnc-SAMD14-4 (lncRNA, FC= 86.11047) was strongly associated with *COL1A1* (mRNA, FC=175.43033) and *COL1A2* (mRNA, FC=85.32694). Type I collagen is a triple helix consisting of two pro- α 1(I) chains encoded by two *COL1A1* genes and one pro- α 2(I) chain encoded by one *COL1A2* gene. Type I collagen is the most abundant collagen of the human body present in scar tissue and it's also regarded as the end product when tissue heals by repair[41], It's reported that Type I collagen are rare in normal chondrocytes but higher levels of Type I collagen was detected in osteoarthritis cartilage, especially in late stages of osteoarthritis[42], it's reasonable to hypothesis lnc-SAMD14-4 may promote *COL1A1* gene and *COL1A2* gene and involved in the pathogenesis of OA. To verify our thoughts, IL-1 β -treated human chondrocytes was used to imitated the gene change in the process of osteoarthritis as previous study[17, 43]. Ours study indicated a positive correlation between lnc-SAMD14-4 and *COL1A1* gene and *COL1A2* gene in IL-1 β -treated human chondrocytes as well as osteoarthritis patients cartilage. Thus, our study suggested lnc-SAMD14-4 might play a key role in the pathogenesis of osteoarthritis by promote *COL1A1* gene and *COL1A2* gene.

Conclusions

Generally speaking, we used the Affymetrix chips and bioinformatics to explore the differential expression lncRNAs between OA articular cartilage and non-OA articular cartilage, Moreover, our study revealed that lnc-SAMD14-4 may promote *COL1A1* gene and *COL1A2* gene and involved in the pathogenesis of OA, which provides a potential therapeutic target for treatment.

Figure 1

Volcano plot and hierarchical clustering of lncRNA and mRNA differential expression profiles between non-OA and OA groups for 10 cartilage tissues.

(A) Volcano plot of dysregulated lncRNA and mRNA (dots denotes gene). Grey spots represent $p > 0.05$; green spots represent $p < 0.05$ and fold-change < 2 . Red spots represent up-regulated genes ($p < 0.05$ and fold-change > 2.0), and blue spots represent up-regulated genes ($p < 0.05$ and fold-change < -2.0). Heatmap of differentially expressed lncRNA (B) and mRNA (C). Colors denote relative expression: red represents high relative expression; green represents low relative expression.

A

B

C

Figure 2

Go analysis of abnormal mRNAs between OA and non-OA groups.

Enriched Go terms targeted by up-regulated mRNAs (A-C) and down-regulated mRNAs (D-F) according to biological processes, cell components, and molecular function ($p < 0.05$ as statistically significant according to a Fisher's exact test).

Figure 3

KEGG pathway analysis of abnormal mRNAs between OA and non-OA groups.

Top 20 pathways targeted by down-regulated (H) and up-regulated (I) transcripts ($p < 0.05$ was statistically significant according to a Fisher's exact test).

LncRNA-mRNA co-expression network.

Green node represents mRNA; red node represents lncRNA. Line indicates a co-expression relationship between lncRNA-mRNA.

Figure 5

qPCR and microarray data.

Values are means + S D (n=3), and * $p < 0.05$ was statistically significant compared to the non-OA group

Figure 6

The mRNA levels of *COL1A1*–*COL1A2* and lnc-SAMD14-4 were detected by QPCR in the IL-1 β -treated human primary chondrocytes

The mRNA expression was normalized to GAPDH expression and conversion by $2^{-\Delta\Delta C_t}$. Values are means + SD (n=3). Data were analyzed using one-way ANOVA followed by Dunnett-t test. * $p < 0.05$ was statistically significant compared to the control group.

A

B

Figure 7

Effects of Inc-SAMD14-4 suppression/overexpression on the relative expression levels of *COL1A1*–*COL1A2* in IL-1 β -treated human primary chondrocytes detected by QPCR

Data were analyzed using one-way ANOVA followed by Dunnett-*t* test. **p* <0.05 was statistically significant compared to the control group.
