Aim: Historically, the distribution of Sandhill Cranes included much of North America and extending in summer into northeast Russia. In recent years, observations of sandhill cranes in Asia during the non-breeding period have been frequently reported. However, the distribution and abundance of sandhill cranes during the non-breeding period in Asia have rarely been summarized and studied. Our study aimed to analyze the status of sandhill cranes that have spread south into East Asia during the non-breeding period and to assess the possible impacts of their potential spread.

Methods: Based on opportunistic data collected in the field and occurrence data collected online over the past half century, we used Geographic Information System to visualize the spatial distribution changes and regression analysis to analyze and visualize the changes in the amount of individuals over time. **Results:** In the last 50 years, the distribution of sandhill cranes during the non-breeding season in Asia spanned 31 degrees in longitude to the west and 15 degrees in latitude to the south. Their distribution in Asia has expanded to 17 provinces and municipalities in China, Japan and South Korea. The amount of cranes in the non-breeding period in Asia increased significantly from 1963 to 2017. According to the historical records in East Asia, sandhill cranes were mixed with five other species of crane groups.

Main conclusions: These results indicate that the range and amount of sandhill cranes have expanded. Sandhill cranes were mixed with five other crane species, which indicate their adaptability to a range of habitat types and food resources. The implications of these trends in sandhill cranes in East Asia for this and other crane species warrants further research.

14 **Abstract**

15 **Aim:** Historically, the distribution of Sandhill Cranes included much of North America and
16 extending in summer into northeast Russia. In recent years, observations of sandhill cranes in
17 Asia during the non-breeding period have been frequently reported. However, the distribution
18 and abundance of sandhill cranes during the non-breeding period in Asia have rarely been
19 summarized and studied. Our study aimed to analyze the status of sandhill cranes that have
20 spread south into East Asia during the non-breeding period and to assess the possible impacts of
21 their potential spread.

22 **Methods:** Based on opportunistic data collected in the field and occurrence data collected online
23 over the past half century, we used Geographic Information System to visualize the spatial
24 distribution changes and regression analysis to analyze and visualize the changes in the amount
25 of individuals over time.

26 **Results:** In the last 50 years, the distribution of sandhill cranes during the non-breeding season in
27 Asia spanned 31 degrees in longitude to the west and 15 degrees in latitude to the south. Their
28 distribution in Asia has expanded to 17 provinces and municipalities in China, Japan and South
29 Korea. The amount of cranes in the non-breeding period in Asia increased significantly from
30 1963 to 2017. According to the historical records in East Asia, sandhill cranes were mixed with
31 five other species of crane groups.

32 **Main conclusions:** These results indicate that the range and amount of sandhill cranes have
33 expanded. Sandhill cranes were mixed with five other crane species, which indicate their
34 adaptability to a range of habitat types and food resources. The implications of these trends in
35 sandhill cranes in East Asia for this and other crane species warrants further research.

36 Introduction

37 The sandhill crane (*G. canadensis*) current perhaps the most abundant of the 15 species of
38 cranes, with a global population of 670,000 to 830,000 in 2018, and it is still increasing
39 (Wetlands International, 2018). The International Union for Conservation of Nature (IUCN)
40 listed the sandhill crane as a species of Least Concern (IUCN, 2017). Sandhill cranes are widely
41 distributed in North America (Johnsgard, 1983, 2008). Historically, the wintering and breeding
42 areas of sandhill cranes were limited to North America, with some flying over the Bering Strait
43 to Asia and breeding in northeastern Russia (Walkinshaw, 1949; Johnsgard, 1983). The
44 distribution map of sandhill cranes in North America is shown in Appendix 1, Figure A1.

45 Among the large populations of sandhill cranes, more than 99% of individuals have
46 migratory habits, and the remaining population is not migratory (Wetlands International, 2018;
47 USFWS, 2018). According to genetic characteristics, the migrating population can be divided
48 into two subspecies: lesser sandhill cranes (*G. canadensis canadensis*) and greater sandhill
49 cranes (*G. canadensis tabida*) (Rhymer *et al.*, 2001; Wetlands International, 2018). The sandhill
50 cranes of the different subspecies in the Mid-continent population (MCP) have different
51 morphologies. For management purposes, migratory sandhill cranes have been grouped into six
52 populations by the U.S. Fish & Wildlife Service (USFWS), despite their subspecies affiliation.
53 (Hanna *et al.*, 2014). The MCP is comprised of both subspecies of sandhill cranes, whereas the
54 other populations are comprised almost exclusively of either the greater or lesser subspecies
55 (USFWS, 2018). It is the lesser sandhill crane subspecies that migrates to East Asia from central
56 North America (Johnsgard, 1983; Jones *et al.*, 2005; Krapu *et al.*, 2011; Krapu *et al.*, 2015).
57 These individuals are part of the largest population of sandhill cranes (MCP), and that population
58 continues to increase in amount and its breeding range in Asia (Dubovsky, 2016, 2017).

59 In the past, the tracking research on sandhill cranes in North America has partially revealed
60 its breeding grounds in Asia. The tracking results showed that approximately 23% of the 133
61 individuals tracked in the MCP fly to Russia during breeding season, most of which were
62 distributed in Chukotka, and a small amount was distributed in Yakut and Koryakia. The spring
63 migration period of the sandhill cranes flying to Russia during the breeding season and wintering
64 in North America lasted an average of 73 days. The cranes arrived at the breeding grounds in
65 mid-May and stayed at the breeding grounds for an average of more than 142 days and left in
66 early September. The autumn migration was much faster than the spring migration, and the
67 sandhill cranes left Russia within 7 days and then moved over 39 days to North America,
68 eventually reaching the wintering grounds in mid-October and staying an average of 46 days
69 (Personal communication with Bysykatova Inga Prokopievna, 2017). Most of the breeding
70 cranes were confined to within 75 km of the coast (Krapu & Brandt, 2005). The migration
71 rhythm of the sandhill cranes that breed in Russia and winter in China, Japan and Korea has not
72 yet been studied.

73 It is speculated that in the 1980s, the total amount of sandhill cranes in the Soviet Union
74 (Russia) may have reached 20,000 (Johnsgard, 1983). Since the early 1990s, sandhill cranes have
75 expanded their distribution to Yakutia with an increased amount of individuals (Personal
76 communication with Bysykatova Inga Prokopievna, 2012). In Yakutia, the amount of sandhill
77 cranes increased by 1.8 times from 1984 to 1994 (Degtyarev, 2008); from 1988 to 2008, the
78 breeding area of the sandhill cranes moved westward by 200-250 km; from 1995 to 2009, the
79 amount of breeding sandhill crane individuals in the tundra region near the Indigirka River
80 increased by 13.3 times (Prokopievna, 2012).

81 Sandhill cranes wintering in East Asia have been reported since 1963, with first reports in
82 Izumi, Japan (Crane Park Izumi, 2017). In 1970, a sandhill crane was recorded mixing with red-
83 crowned cranes (*G. japonensis*) in Hokkaido, Japan. In 1979, sandhill cranes were recorded for
84 the first time in Jiangsu Province, China (Masatomi, 1972; Kuang *et al.*, 1981). In recent years,
85 an increasing amount of sandhill cranes have been recorded in China, Japan and Korea during
86 non-breeding periods (Harris & Mirande, 2013; Cheng *et al.*, 2014; Crane Park Izumi, 2017). In
87 the winter of 2017, only 7 sandhill cranes were recorded in Japan (Crane Park Izumi, 2017). It
88 has been suggested that the status of the sandhill cranes in China should be defined as rare winter
89 birds (Cheng *et al.*, 2014). The IUCN Red List has also changed its status in China, Japan, and
90 South Korea from straggler birds to a naturally distributed species (IUCN, 2017).

91 However, the temporal and spatial characteristics of the distribution of sandhill cranes in
92 East Asia during the non-breeding period have not yet been summarized and analyzed
93 systematically. With that aim, we collected data from the field, online and the spatial and
94 quantity changes of the cranes that have been analyzed over time. Our study clarifies the changes
95 in the distribution and the amount of sandhill cranes in East Asia during the non-breeding period
96 in the past half century.

97 **Materials & Methods**

98 **1. Data collection:**

99 The data sources for this study consist of 5 parts.

100 1.1 Field Data Source

101 During the 8 years from 2008 to 2015, we collected the amount and the distribution data of
102 sandhill cranes while conducting field surveys of other crane species in China and Japan.

103 From 2008 to the present (2018), we carried out field investigations of Northeast Asian
104 cranes, including hooded cranes (*G. monacha*), white-naped cranes (*G. vipio*), red-crowned
105 cranes, Siberian cranes (*G. leucogeranus*), demoiselle cranes (*Anthropoides virgo*) and Eurasian
106 cranes (*G. grus*) in the spring, autumn and winter. The spring survey time was from mid-March
107 to the end of April, and the autumn survey time was from mid-September to mid-November. The
108 locations were on the edge of the Songnen Plain and the Xiaoxing'an Mountains in Northeast
109 China (Zhalong, Xinqing, Dazhan River, and Lin Dian, Momo Ge, Xiang Hai, etc.). The winter
110 survey period was from the end of November to the following March in the middle and lower
111 reaches of the Yangtze River (Jiangsu, Anhui, etc.). In the winters of 2010 and 2014, we visited
112 Japan for a short period of time to understand the wintering situation of the hooded crane. Using
113 the telescope direct observation method for all the field research on the cranes in Northeast Asia,
114 we have been paying attention to the presence of sandhill cranes and recording them in time.

115 1.2 Paper Source

116 By searching the "Chinese Knowledge Network" (<http://www.cnki.net>); "Web of Science"
117 (<http://apps.webofknowledge.com/>) and other database systems, we collected new records of
118 sandhill cranes released in and before 2017 by searching "sandhill cranes". Additionally,
119 accessible data on the location, time, and quantity of sandhill cranes were collated. All of the
120 new records were included in our research.

121 1.3 News and Bird Watching Websites Source

122 Through searching domestic and international websites, we identified news and bird-
123 watching records of sandhill cranes. Using the Chinese search engine "Baidu"
124 (<https://www.baidu.com/>) and other online public platforms, sighting records and news of
125 sandhill cranes were collected. The sighting records and news of sandhill cranes in Korea were
126 gathered through online public platforms such as the Korean search engine "NAVER"
127 (<https://www.naver.com/>). For the records in Japan, the Google search engine
128 (<https://www.google.com/>) was used. All the searches were based on the words "sandhill cranes"
129 and "news". Some of the bird watching information provided by birdwatchers was verified with
130 photos. For the records without photos, we first judged whether there was more than one
131 distribution record of sandhill cranes in this area, and then filtered data by determining whether the
132 site was suitable for cranes. If it was true, the record was used in this study. All the information
133 for the data analysis in this paper was used after deduplication.

134 1.4 Global Biodiversity Information Facility Source

135 The Global Biodiversity Information Facility (GBIF) (<http://www.gbif.org/>) is an open data
136 research site funded by various governments that provides data on species across the world. We
137 downloaded the distribution data of sandhill cranes in Asia and excluded Russia (which is a
138 breeding area for the species) from 1950 to 2017.

139 1.5 Crane Museum of Izumi, Japan

140 We collected the time and amount information of sandhill cranes recorded in Izumi,
141 Kagoshima City, Japan from 1963-2017 on the website of "Japanese Izumi Crane Museum"
142 (<http://www.city.kagoshima-izumi.lg.jp/>).

143 2. Data analysis:

144 2.1 Data filter

145 We deleted data with incomplete information (missing the year or the place of sighting) and
146 obtained the latitude and longitude in Google Maps using the name of the recorded place.
147 Duplicated data were removed by checking the time, place, and recorder information. The final
148 data included time (year/month/day), year (winter), the name of the place, the latitude and
149 longitude, the sources of information, the age of the individuals, whether a family group was
150 recorded, whether the sandhill crane was mixed with other cranes and what crane species it was
151 mixed with, and other additional information. If the data included information on month, and the
152 month of observation was in January-May, then the record was assigned the previous year, to
153 indicate the bird(s) was considered to have been present in East Asia that entire winter. The data
154 without month information were recorded as the winter of the current year.

155 We also recorded the geographical location and the amount of species that the cranes were
156 mixed with; the year and the geographical location that only included subadult individuals; and
157 the year and geographical location in which the family groups appeared.

158 2.2 Distribution Change Analysis

159 The data were classified according to the year (due to the large time span, the amount of data
160 was relatively small before 2000 and the data were not evenly divided by year). The data were
161 artificially attributed to three different periods: before 2000 (1963-1999), 2000-2009, and 2010-
162 2017. We used ArcGIS 10.1 to create maps for the different periods of time.

163 2.3 Quantity Changes in Successive Years

164 When data were recorded multiple times in the same place within the same year, only one
165 piece of data with the largest amount of individuals was kept while the others were deleted. The
166 years from 1963 to 2017 with no records were included with the amount of observations was
167 defined as zero. At the same time, the data with observation records but with no exact
168 quantitative data were defined as 1. Finally, we created a counting table of the sandhill cranes
169 during the non-breeding period in Asia (see data source in Appendix, Table A1).

170 Different power polynomial regressions were performed on the year (x) and the amount of
171 individuals (y). To obtain the overall fluctuation trend of the sandhill cranes over the past 55
172 years and to reduce the impact of data differences in individual years on the overall trend fitting,
173 a simple mean value filter was applied to the original data to reduce the impact of the overall
174 trend from a single piece of data. We took the filter window length as $n = 10$ years (taking the
175 mean data value from 1963-1972 as the amount of cranes in 1967) and the specific step length as
176 $n = 1$ year (the step length in 1 year). We used Python 3.6.1 to conduct a mean value filter and
177 calculate the coefficient of determination, the “numpy” packages for the polynomial fitting, and
178 the “matplotlib” packages for the data visualization.

179 Results

180 During the 55 years from 1963 to 2017, a total of 169 valid data points (including locations
181 and years simultaneously) were obtained for the distribution of sandhill cranes.

182 The results of the field survey were as follows. In 2009, one sandhill crane was found in
183 Xinqing Wetland Park in Yichun, Heilongjiang Province. In 2011, 2014 and 2015, one sandhill
184 crane was found in the Zhalong Nature Reserve in Heilongjiang Province each year. In 2015, one
185 sandhill crane was observed in Caizi Lake, Anhui Province. In Izumi, we observed sandhill
186 cranes mixed with hooded cranes and had photos. The results of this part of the field work survey
187 are also included in the website of the Crane Museum of Izumi. In February 2010 and January
188 2014, 1 to 3 sandhill cranes were observed in Izumi, Japan. During the 6 years of 2008, 2009,
189 and 2011 to 2014, 1 ~ 4 sandhill cranes were observed and photographed in the Yancheng
190 National Wetland Nature Reserve for Rare Birds in Jiangsu province. The other 4 methods
191 obtained 21, 44, 52, and 38 pieces of data, respectively, as shown in Table 1.

192 1. Mixed, Subadult, Adult and Family Records

193 There are 29 pieces of data clearly record whether the sandhill cranes were active
194 independently or mixed with other crane species among all the data. The data shows that sandhill
195 cranes were only observed with other cranes species, and never reported away from other crane
196 species during the non-breeding period in east Asia. They were reported to have mixed with the
197 following 5 species of cranes distributed in the same period: white-naped crane, Siberian crane,
198 hooded crane, Eurasian crane and red-crowned crane (see Figure 1).

199 Regarding whether it was a subadult, there were three clear records showing that a subadult
200 was mixed alone with other crane species. These records appeared in 1969, 1984 and 2014,
201 respectively, in Hokkaido, Jiangxi, and Hebei in Japan and China; one record showing that a
202 family group was mixed with other crane species; 18 records showed an adult mixed with other
203 crane species; and 7 pieces of data were missing this kind of information.

204 As for the type of group, the records of the sandhill cranes mostly consisted of 1 ~ 3
205 individuals that were not a family group. In recent years, there were 2 records showing that there
206 were already sandhill crane family groups in Asia during the non-breeding period. One family
207 group was recorded in Yancheng National Wetland National Nature Reserve for Rare Birds,
208 Jiangsu, China on December 4, 2013, with 2 juveniles in the reserve. The second was recorded in
209 Kagoshima, Japan, on November 7, 2014, also with 2 juveniles recorded.

210 2. Analysis of individual amount changes

211 A total of 86 pieces of data were retrieved from 1963 to 2017 after de-duplicated. Finally, 98
212 pieces of data were obtained for the statistical analysis of the individual amount changes in
213 successive years after supplementing the years without sandhill crane observation records as zero.
214 Since the sample determination coefficient of the 3, 4 and 5 polynomial fitting results after the
215 filter processing showed no significant differences (0.007), to avoid overfitting, no higher-order
216 polynomial fitting was performed in this study, and the 3 polynomial fitting results were selected.
217 The results of the cubic polynomial fitting before and after the filtering process are shown in
218 Figure 2, and the polynomial fitting results for other powers are shown in Appendix, Figure A2.

219 The results of the cubic polynomial fitting curve show that the amount of sandhill cranes
220 during the non-breeding period in Asia increased significantly from 1963 to 2017. Before 1997,
221 their quantity increased slowly with 0.06 individual per year. Since 1997, their amount grown
222 rapidly with 2.53 individuals per year.

223 3. Distribution change analysis

224 From 1963 to 2017, the non-breeding distribution area of the sandhill cranes in Asia reached
225 its westernmost extent at the Yellow River Wetland National Nature Reserve (113°E) in Henan
226 Province, China on November 11, 1999; the easternmost extent of the distribution was reached at
227 Hokkaido (144°E), Japan on January 18, 1970; the southernmost extent was reached at Poyang
228 Lake Nature Reserve (29°N) in Jiangxi Province, China on February 14, 1985; the northernmost
229 distribution was reached at Xinqing wetland (48°N) in Heilongjiang Province, China, on
230 September 18, 2009. The distribution spans 31 degrees in longitude and 19 degrees in latitude.

231 The distribution area of the cranes has increased over time. Thirty records showed that
232 before the year 2000, sandhill cranes were distributed in 6 areas in Shuyang, Jiangsu; Yancheng,
233 Jiangsu; Poyang Lake, Jiangxi; Yellow River Delta Nature Reserve, Shandong; and Yellow
234 River Wetland Nature Reserve, Henan in China and Kagoshima and Hokkaido in Japan; Korea
235 had no record during this period. An additional 5 areas were recorded in the following period
236 from 2000 to 2009. There were 52 records showed that the distribution area of the cranes in
237 China expanded to Zhalong National Nature Reserve, Heilongjiang; Momoge National Nature
238 Reserve, Jilin; Xinqing Wetland, Heilongjiang; and Nanjing and Shanghai. Meanwhile, sandhill
239 cranes were recorded in Suncheon Bay Wetland, Jeollanam and Seosan, Chungcheongnam in
240 Korea. An additional 6 areas were recorded in the following period from 2010 to 2017. There
241 were 87 records showed that their distribution area in China has expanded to Guanzidong
242 wetland, Liaoning; Miyun Reservoir, Beijing; Lianyungang, Jiangsu; Tangshan, Hebei; and
243 Caizihu, Anhui. Their distribution points in Japan increased to Ibaraki, and in Korea, their
244 distribution increased to Cheolwon, Gangwon, see Figure 3.

245 In China, sandhill cranes were distributed in 11 provinces and municipalities, including
246 Heilongjiang, Jilin, Liaoning, Hebei, Beijing, Shandong, Henan, Jiangsu, Anhui, Shanghai and
247 Jiangxi. In Japan, sandhill cranes were distributed in three provinces and cities, including
248 Kagoshima in the south, Ibaraki in the east, and Kushiro, Hokkaido in the north. In Korea,
249 sandhill cranes were distributed in Suncheon Bay Wetland, Jeonnam in the south and Seosan,
250 Chungcheong and Ibaragi, Gangwon in the north.

251 Discussion

252 Sandhill cranes are the most numerous among all the species of cranes in the world and are
253 still on the rise (Wetlands International, 2018). The sandhill cranes that breed in northeastern
254 Russia have increased. From 1995 to 2009, their amount in a model site in tundra near Indigirka River
255 in summer grew 13.3 times. The expansion trend is both in their amount and their distribution areas
256 (Personal communication with Bysykatova Inga Prokopievna) (Degtyarev, 2008; Prokopievna,
257 2012).

258 The results of our study show that the distribution area of the sandhill cranes in East Asia
259 during the non-breeding period was increasing, and the amount of individuals was also
260 increasing each year (see Figures 2 and 3). Therefore, their distribution and amount in Asia
261 during the non-breeding stages may be undergoing a process similar to that in Russia. Before
262 1963, there were no records of sandhill cranes wintering in Asia (Crane Park Izumi, 2017). The
263 reports before 2013 regarding the wintering records of the sandhill cranes were all sporadic
264 individuals who mixed with other crane groups, indicating that these individuals may come to
265 Asia together with other crane species by some accidental factors that occurred in the breeding
266 grounds or the stopover sites. Therefore, it is reasonable to define sandhill cranes as “vagrant”
267 (Masatomi, 1972; Wang *et al.*, 2007; Zheng, 2011). In the past decade or so, the frequency and
268 location of records have increased (see Figures 2 and 3). Sandhill cranes wintering in Asia
269 represent almost a normal phenomenon that continues to expand. In the winters of 2013 and
270 2014, a family group was recorded in Yancheng, Jiangsu, China and Izumi, Kagoshima, Japan
271 respectively. Both of these records were found in the regions with the largest amount of data, and
272 also have relatively stable observation records of sandhill cranes. These individuals may come
273 from northeastern Russia. They chose a relatively short path to winter in Asia. This is also in line
274 with the time-minimization and energy-minimization strategies of migratory birds (Zhao *et al.*,
275 2017). Although coming to Asia for the winter is more in line with time-minimization and
276 energy-minimization strategies. However, due to the habit of migration and the role of old birds
277 in the migration of birds, there were no large amount of sandhill cranes recorded during the
278 winter in Asia (Mueller *et al.*, 2013). Although the amount is now few, the definition of “vagrant”
279 is insufficient to describe their current wintering distribution status based on the long-term stable
280 records (see Figure 1 and 2). Based on this study, we defined the status of the wintering of
281 sandhill cranes in China as “rare winter migratory birds” (Cheng *et al.*, 2014) and suggested that
282 the sandhill cranes in East Asia (China, Japan, and South Korea) also be defined as “rare winter
283 migratory birds”. The records of the family group of sandhill cranes in Asia in winter indicate
284 that there are adult birds who lead the juveniles to migrate to Asia now. We assume that there
285 may be more family groups that show up in the future and then expand their wintering groups in
286 Asia to finally form a stable wintering population. Sandhill cranes will become a real “winter
287 bird” in Asia. It’s worth mentioning that the inevitable limitation of data used in this research,
288 such as 1) potential misidentification between sandhill crane and other crane species; 2)
289 increasing recorded sandhill crane individual numbers possibly influence by rising number of
290 bird watchers, and 3) those observation records without exact individual amount were defined as
291 only “1” individual in the data analysis. In the future, it could be further supplemented by the
292 development of professional abilities (species identification and data collection) of bird watchers.
293 It is also important to conduct long-term continuous monitoring in key wintering sites of sandhill
294 crane in East Asia.
295

296 There were three clear records of subadult individuals wintering alone with other crane
297 species in Asia, the earliest in 1969. There may have been additional occurrences of subadult
298 wintering in East Asia that were not detected because of limitations of field identification
299 abilities. That most of the records of subadult were sporadic (1969, 1984, and 2014) may reveal
300 the role of subadult in the winter range expansion of sandhill cranes. The subadult distribution
301 records show that subadults were recorded as early as 1969, and most of their occurrences were
302 rarely recorded again in the future, which may also reveal the role of subadult in the expansion of
303 sandhill cranes. The records of the subadult individuals are valuable in judging the spread
304 mechanism of cranes. According to a study on the spread of the greater flamingo
305 (*Phoenicopterus ruber*) in China, subadults were observed in high proportions in their expansion
306 areas (79.2%) (Zhu *et al.*, 2017). Therefore, subadults may be the initiators and implementers of
307 the spread of the greater flamingo. From the three subadult records in this paper, it is difficult to
308 determine whether the increase in occurrence of sandhill cranes in Asia is similar to the
309 proliferation of the greater flamingo, and it remains to be further studied. In addition, if the
310 mixture of sandhill and other crane species individuals is selective or opportunistic might also
311 relevant to its expansion mechanism and deserves more studies in the future.

312 Regarding the distance of the migration path, sandhill cranes that breed in Russia may have
313 more advantages wintering in Asia than in their traditional wintering grounds in North America.
314 The shorter distance in East Asia may reduce energy consumption during migration (Zhao *et al.*,
315 2017). In addition, East Asia is an important wintering ground for many kinds of cranes. Sandhill
316 cranes have similar habitat requirements to other crane species, such as the Eurasian crane and
317 the red-crowned crane, in non-breeding seasons. Therefore, East Asia can provide them with
318 adequate food and suitable habitats (Hunt *et al.*, 1996; Cheng *et al.*, 2014). Meanwhile, sandhill
319 cranes can adapt to locally available herbivorous food resources, especially grains (Johnsgard,
320 1983). Good adaptability is also the basis for the species' further spread in Asia. With the
321 increase of sandhill cranes in Asia during winter, there may be more sandhill cranes following
322 the experienced old individuals migrating to Asia (Mueller *et al.*, 2013). The wintering
323 distribution of sandhill cranes in Asia may develop into a forward and directional expansion
324 instead of following the other crane species.

325 The increase in sandhill cranes in Asia to become a winter bird may cause the following
326 potential problems. First, in terms of disease transmission, sandhill cranes have the ability to
327 carry and spread infectious diseases between North America and Asia. Previous studies have
328 shown that sandhill cranes and other waterbirds can transmit highly pathogenic avian influenza
329 viruses between Asia and North America (Winker *et al.*, 2007; Winker & Gibson, 2010).
330 Meanwhile, the results of the study that focused on the two large populations of sandhill cranes
331 in North America showed that the population (MCP) that will migrate to Asia has a higher
332 chance of being exposed to pathogens and parasites. Coccidian (*Sphaerozoum fuscum*) can be
333 disseminated to the endangered whooping crane by sandhill cranes (Hensel *et al.*, 2017). Highly
334 pathogenic avian influenza infection and other diseases derived from coccidia and coccidiosis are
335 all potential future impacts of sandhill cranes on other crane species in Asia. Second, since there
336 have been records of field hybrids of sandhill cranes with whooping cranes (*G. Americana*) and
337 Eurasian cranes, sandhill cranes may hybridize with other crane species (record from ebird,
338 www.ebird.org). Genetic studies have shown that compared to white-naped Cranes, whooping
339 cranes, hooded cranes, Eurasian cranes, Siberian cranes and demoiselle cranes, sandhill cranes
340 have the closest genetic distance to red-crowned cranes (Guo *et al.*, 2012). Therefore, it remains

341 to be seen whether there will be hybrids of sandhill cranes and what it means for the endangered
342 (EN) red-crowned cranes in the future (IUCN, 2017).

343 At the point of interspecific competition, studies have shown that the massive breeding of
344 sandhill cranes in northeastern Russia has already exerted competitive pressure on Siberian
345 cranes (Germogenov *et al.*, 2015). During the nonbreeding season, most species of cranes have
346 fairly similar foraging habits (grains, seeds, tubers), and sandhill cranes are known to be one of
347 the most generalist species (Reinecke *et al.*, 1986; Jesús M.A. *et al.*, 2002; Zhao *et al.*, 2002).
348 Therefore, they are likely to overlap in habitat and foraging with other crane species in Asia.
349 That might be an important influence that sandhill crane will bring. The further influence of
350 these pressures on endangered cranes remains to be further studied. Because the sandhill cranes
351 were mixed with five other species of cranes in Asia during the non-breeding period (Figure 1),
352 once they have released their huge potential expansion ability, they will have a serious impact on
353 those species that have long been distributed in Asia, especially for the red-crowned cranes,
354 Siberian cranes, hooded cranes and white-naped cranes. These impacts are what we ought to
355 focus on, and they should be prevented in advance.

356 Conclusions

357 Since the first record of sandhill crane wintering in Asia in the 1960s, its wintering
358 distribution area here has expanded, and its number of individuals has also increased over time.
359 This phenomenon is closely related to the steady growth trend of its source population in North
360 America and the growing and expansion trend of them during summer time in Asia. In recent
361 years, family groups of sandhill cranes has been recorded wintering in Asia, and not just a single
362 individual anymore. According to the current situation, the wintering individuals in Asia have a
363 potential tendency of increasing. Once it happens, it will have a series of effects on other crane
364 species that are wintering in the same region in Asia.

365 Up to now, there has been no designed field investigation for sandhill cranes. Our research
366 has clarified the situation of sandhill cranes wintering in Asia since the first records. But research
367 on its wintering status is still difficult to conduct. In the future, we can predict the possible
368 wintering area by using the species distribution model to narrow the scope of research and
369 conduct further study on it. Related researches are of great significance to the study of the
370 expansion mechanism in a new environment of the crane which has the largest number of
371 individuals around the world. It can also estimate the possible impact of the expansion of
372 sandhill cranes and to develop appropriate management approaches on it.

Acknowledgements

373 We thank the GBIF team for making their database available freely and all the people who
374 contributed to the open access data. We appreciate Bysykatova Inga Prokopievna for providing
375 the manuscripts about sandhill cranes in Russia. We greatly thank Huajin Sun in Yancheng,
376 China, for supplying us with his photographic records in Yancheng. We thank Xiaolong Liu, Jun
377 Wang and Chuyu Cheng for comments on previous versions of this manuscript. We are grateful
378 to Falk Huettmann and Qi Cong for their suggestion on our analysis methods. This study has
379 been supported by the State Forestry Administration and the Grassland Bureau. Primary funding
380 was from the National Natural Science Foundation of China awarded to Yumin Guo (grant no.
381 31570532).

Figure 1

The mix distribution map of sandhill cranes in Asian during the non-breeding period.

This figure depicts the mixed position of the sandhill crane with five other crane species in Asia. The cross represents the cranes mixed with the white-naped crane, the snowflake represents the cranes mixed with the Siberian crane, the triangle represents the cranes mixed with the common crane, and the square represents the cranes mixed with the red-crowned crane.

Figure 2

Cubic polynomial fitting curve of the number of sandhill cranes in Asia during the non-breeding period from 1963 to 2017.

Figure (a) is a scatter plot of the number of the sandhill cranes in Asia in the past half century and its cubic fitting curve; Figure (b) is a scatter plot of the number of the sandhill cranes in Asia in the past half century and its cubic fitting curve after performing a simple mean value filter.

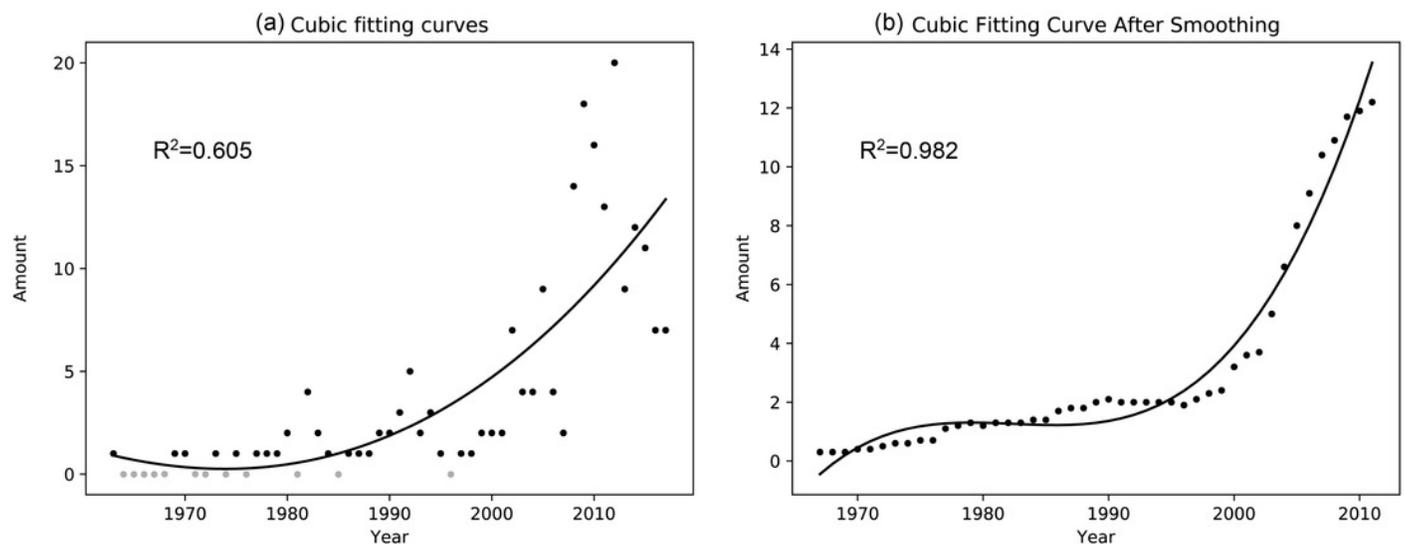

Figure 3

Distribution map of the sandhill cranes in Asia during the non-breeding period.

Figure (a) is a schematic diagram showing the distribution of sandhill cranes in East Asia during the non-breeding period before 2000; Figure (b) is a schematic diagram showing the distribution of sandhill cranes in East Asia during the non-breeding period before 2009; Figure (c) is a schematic diagram showing the distribution of sandhill cranes in East Asia during the non-breeding period before 2017. The red circle indicates the distribution point between 2010 and 2017; the blue circle indicates the distribution point between 2000 and 2009; and the green circle indicates the distribution point before 2000. The light pink box indicates that the number of distributed records in this area is from 1 to 10; the pink box indicates that the number of distributed records in this area is from 10 to 20; and the red box indicates that the number of distributed records in this area is from 20 to 40.
