Background. *Lecanicillium lecanii* is an entomopathogenic fungi, which was isolated from insect suffer from a disaster. Now, it is an effective bio-control resource that can control agricultural pests such as whitefly and aphids. There are many studies on the control of various agricultural pests by *L. lecanii*, but no report on its control of *Bemisia tabaci* biotype-Q exists. In this work we studied the susceptibility of *B. tabaci* Q-biotype (from Ningxia, China) to *L. lecanii* JMC-01 in terms of nymph mortality and the changes in detoxifying protective enzymes activities. **Methods.** *Bemisia tabaci* nymphs were exposed to *L. lecanii* JMC-01 conidia by immersion with the host culture. Mortality was assessed daily for all nymph stages. The detoxifying and protective enzyme activity changes, weight changes, and fat, and water contents of the nymphs were determined spectrophotometrically. **Results.** All instars of *B. tabaci* died after being infested with 1×10^8 conidia/mL. The 2nd-instar nymphs were the most susceptible, followed by the 3rd-instar nymphs. The corrected cumulative mortality of the 2nd- and 3rd-instar nymphs was 82.22% and 75.55%, respectively. The levels of detoxifying and protective enzymes initially increased and then decreased. The highest activities of carboxylesterase (CarE), acetylcholinesterase (AChE), peroxidase (POD), and catalase (CAT) occurred on the 3rd day, reaching 10.5 U/mg prot, 0.32 U/mg prot, 20 U/mg prot, and 6.3 U/mg prot, respectively. These levels were 2.2-fold, 4.3-fold, 2.4-fold, and 1.4-fold the control levels, respectively. The highest activities of glutathione-S transferase (GSTs) and superoxide dismutase (SOD) on the 2nd day were, respectively, 64 U/mg prot and 43.5 U/mg prot. These levels were, respectively, 2.7-fold and 1.1-fold that of the control level. The water and fat content in the infected *B. tabaci* nymphs decreased and differed significantly from the control levels. The weight increased continuously in the first 24 h, decreasing thereafter. At 72 h, the infestation level was about 0.78-fold that of the control level. **Conclusions.** The studied *L.*

lecanii JMC-01 strain is pathogenic to the *B. tabaci* Q-biotype. This strain interferes with the normal functioning of detoxifying and protective enzymes, and is also involved in the disruption of normal physiological metabolism in *B. tabaci*.

16 Abstract

17 **Background.** *Lecanicillium lecanii* is an entomopathogenic fungi, which was isolated from
18 insect suffer from a disaster. Now, it is an effective bio-control resource that can control
19 agricultural pests such as whitefly and aphids. There are many studies on the control of various
20 agricultural pests by *L. lecanii*, but no report on its control of *Bemisia tabaci* biotype-Q exists. In
21 this work we studied the susceptibility of *B. tabaci* Q-biotype (from Ningxia, China) to *L. lecanii*
22 JMC-01 in terms of nymph mortality and the changes in detoxifying protective enzymes
23 activities.

24 **Methods.** *Bemisia tabaci* nymphs were exposed to *L. lecanii* JMC-01 conidia by immersion with
25 the host culture. Mortality was assessed daily for all nymph stages. The detoxifying and
26 protective enzyme activity changes, weight changes, and fat, and water contents of the nymphs
27 were determined spectrophotometrically.

28 **Results.** All instars of *B. tabaci* died after being infested with 1×10^8 conidia/mL. The 2nd-instar
29 nymphs were the most susceptible, followed by the 3rd-instar nymphs. The corrected cumulative
30 mortality of the 2nd- and 3rd-instar nymphs was 82.22% and 75.55%, respectively. The levels of
31 detoxifying and protective enzymes initially increased and then decreased. The highest activities
32 of carboxylesterase (CarE), acetylcholinesterase (AChE), peroxidase (POD), and catalase (CAT)
33 occurred on the 3rd day, reaching 10.5 U/mg prot, 0.32 U/mg prot, 20 U/mg prot, and 6.3 U/mg
34 prot, respectively. These levels were 2.2-fold, 4.3-fold, 2.4-fold, and 1.4-fold the control levels,
35 respectively. The highest activities of glutathione-S transferase (GSTs) and superoxide dismutase
36 (SOD) on the 2nd day were, respectively, 64 U/mg prot and 43.5 U/mg prot. These levels were,
37 respectively, 2.7-fold and 1.1-fold that of the control level. The water and fat content in the
38 infected *B. tabaci* nymphs decreased and differed significantly from the control levels. The
39 weight increased continuously in the first 24 h, decreasing thereafter. At 72 h, the infestation
40 level was about 0.78-fold that of the control level.

41 **Conclusions.** The studied *L. lecanii* JMC-01 strain is pathogenic to the *B. tabaci* Q-biotype. This
42 strain interferes with the normal functioning of detoxifying and protective enzymes, and is also
43 involved in the disruption of normal physiological metabolism in *B. tabaci*.

44

45 Introduction

46 The whitefly or tobacco whitefly *Bemisia tabaci* (Gennadius) (Hemiptera: Aleyrodidae) is a
47 cosmopolitan insect pest with more than 900 documented host plant species. This species is
48 considered to belong to a cryptic species complex with more than 40 morphotypes distributed
49 across the biotypes, with the B- and Q-biotypes being the most important (Tang et al., 2018). The
50 whitefly is of economic importance due to its direct (by sapping plant fluids and vectoring plant
51 pathogens) and indirect (phytosanitary and quarantine measures) damage to crops (Barro, 2011;
52 Xu et al., 2014). Its control mainly relies on chemical pesticide application, which has resulted in
53 the development of insecticide resistance. In addition to the emergence of resistant strains, farms
54 and other stakeholders are challenged by safety concerns. Pesticide application causes

55 environmental pollution, alters the abundance of natural enemies, increases pest resistance and
56 promotes secondary pest population resurgence (Liu et al., 2009). Environmentally-friendly pest
57 management methods, such as biological control using natural enemies and entomopathogen
58 microorganisms (bacteria, fungi and viruses) are being established worldwide in response to this.

59 Entomopathogenic fungi were the first microorganisms identified as insect pathogens, whereas
60 entomopathogenic bacteria were the first to be commercialized (Lacey et al., 2001) .

61 *Lecanicillium lecanii* [= *Verticillium lecanii* (Zimmerman) Viegas] belongs to Deuteromycotina,
62 Hyphomycetes, Moniliales, Moniliaceae, that is widely use entomopathogenic fungi in bio-
63 control up to now. And the entomopathogenic fungal species described and commercialized,
64 *Lecanicillium lecanii* (Zare and Gams, 2001) deserves further consideration as a broad range
65 commercial biopesticide, due to its wide range of hosts and wide geographical distribution (Xie
66 et al., 2015). Indeed, this species can infect the diamondback moth *Plutella xylostella* (L.)
67 (Lepidoptera: Plutellidae) (Keppanan et al., 2018), aphids (Hemiptera: Aphididae) (Askary et al.,
68 1999), the citrus mealybug *Planococcus citri* Risso (Hemiptera: Pseudococcidae) (Ghaffari et al.,
69 2017), and the soybean cyst nematode *Heterodera glycines* Ichinohe (Tylenchida: Heteroceridae)
70 (Shinya et al., 2008), and has also been documented to infect *B. tabaci* (Zhu and Kim, 2011). In
71 insects, the spores of entomopathogenic fungi germinate, and the fungal hyphae penetrate the
72 epidermis and invade the tissues and organs until reaching the haemocoel (Duan et al., 2017).
73 When the hyphae come into contact with the hemolymph, the defense system of the insects,
74 which includes detoxifying and protective enzymes, is induced (Liu et al., 2013).

75 Physiological and biochemical approaches have been used to describe the chronological
76 events leading to fungal infestation success in an insect host. Reactive oxygen species (ROS) are
77 forms of atmospheric oxygen (Tian et al., 2016b) produced in the mitochondria that are
78 equilibrated by cellular antioxidative mechanisms (Esmail et al., 2018). In many instances,
79 microbial pathogens are associated with an increase in ROS, which induces an oxidative stress
80 response in the host (Foyer and Noctor, 2013). The antioxidative mechanism of the cells includes
81 antioxidant enzymes, such as catalase (CAT), superoxide dismutase (SOD) and peroxidase
82 (POD), which degrade H₂O₂ to reduce oxidative damage (Felton and Summers, 1995). In
83 addition to this antioxidative mechanism, insects also harbor detoxifying enzymes, such as
84 carboxylesterase (CarE), glutathione-S transferase (GST), and acetylcholinesterase (AChE),
85 which are able to metabolize exogenous toxicants (Xu et al., 2006), and have been the target of
86 insecticide synergist research (Wang et al., 2016). The effects of these insect detoxifying
87 enzymes in response to the fungal entomopathogen *L. lecanii* in the spiraling whitefly
88 *Aleurodicus dispersus* Russell (Hemiptera: Aleyrodidae) have recently been demonstrated (Liu et
89 al., 2013) . These changes in defensive enzymes are deserving further attention, due to its
90 practical considerations.

91 Due to the lack of studies and the economic importance of *B. tabaci*, the objective of this
92 study was to determine the pathogenic effect of *L. lecanii* strain JMC-01 at the nymphal stages of
93 *B. tabaci* by evaluating accounting the disruption of immune mechanisms.

94

95 **Materials & Methods**

96 **Entomopathogen strain and insect collection**

97 *Lecanicillium lecanii* strain: the *L. lecanii* strain JMC-01 was isolated from *B. tabaci* infected
98 nymphs from a greenhouse in Yinchuan, Ningxia (N 38°33', E 106°08'), China in May 2017.
99 The JMC-01 strain was deposited at the China Center for Type Culture Collection (CCTCC)
100 with the accession number M 2018303. The strain status was determined based on ITS sequence
101 divergence to the reference strain (Jiang, 2018). The JMC-01 strain reference ITS nucleotide
102 sequence was deposited in GenBank with the identification number MH312006.
103 Insect: the whitefly *B. tabaci* Q-biotype was collected from a tomato greenhouse in Yinchuan,
104 Ningxia (N 38°33', E 106°08') in July 2018. Biotype assignment was performed as previously
105 described (Gao, 2018). The tomato cultivar Bijiao was planted in a greenhouse in Yinchuan,
106 Ningxia (N 38°33', E 106°08') and cultivated using drip irrigation technology. Tomato was used
107 as the host plant for two generations, following which the synchronized 3rd-instar nymphs were
108 collected for experimentation.

109

110 **Preparation of the *L. lecanii* JMC-01 conidial suspension**

111 The *L. lecanii* JMC-01 strain was inoculated on potato dextrose agar (PDA) plates, at 28°C with
112 a 12:12 (L:D, light:dark) photoperiod for 7 d (MJ-250 Mould Incubator, Jiangsu Zhengji
113 Instruments Co. Ltd., Jiangsu, China). Spore suspensions were prepared by recovering the
114 conidia from the PDA plates with a w = 0.05% Tween-80 solution. The solution was filtered
115 with sterile cheesecloth to eliminate the hyphae, following which the concentration was adjusted
116 to 1.0×10⁸ conidia/mL with sterile water using a hemocytometer (Qiujiing, Shanghai, China).

117

118 ***Bemisia tabaci* nymph mortality induced by *L. lecanii* JMC-01**

119 Tomato leaves with 1st-, 2nd-, 3rd-or 4th-instar nymphs (only one leaf was selected for each instar
120 nymph) were immersed in *L. lecanii* JMC-01 solution at 1.0×10⁸ conidia/mL for, 30s or in a
121 control solution of w = 0.05% Tween-80. After immersion, each leaf was sealed in a standard
122 Petri dish, with its petiole wrapped in a moistened cotton ball. The plates were incubated in an
123 artificial climate chamber (RQX-250, Shanghai Yuejin Medical Devices Co., Ltd., Shanghai,
124 China) at 28±2°C, 70±10% RH, and 12:12 (L:D) photoperiod. There were three replicates per
125 treatment. Deaths were recorded daily, and the cumulative corrected mortality was calculated as
126 follows:

127

$$128 \quad \text{Accumulative corrected mortality (\%)} = \frac{\text{Infection mortality} - \text{Control mortality}}{1 - \text{Control mortality}} \times 100\%$$

129

130 **Susceptibility of 3rd-instar *B. tabaci* nymphs to different JMC-01 concentrations**

131 The *L. lecanii* JMC-01 suspensions were prepared as described above at different conidial
132 concentrations: 1×10⁸, 1×10⁷, 1×10⁶, 1×10⁵, and 1×10⁴ conidia/mL.

133 Three tomato leaves with 3rd-instar *B. tabaci* nymphs were immersed for, 30 s at each JMC-01
134 test concentration, and the leaves were incubated as described above. Deaths were recorded on a
135 daily basis, and were used to determine the cumulative corrected mortality for each conidial

136 concentration.

137

138 **Protective and detoxifying enzyme activity determination**

139 Tomato leaves with 3rd-instar *B. tabaci* nymphs were infected with *L. lecanii* JMC-01 at 1×10^8
 140 conidia/mL, using the immersion procedure described above. Treated and control (w = 0.05%
 141 Tween-80) leaves were immersed in *L. lecanii* JMC-01 solution at 1.0×10^8 conidia/mL for 30 s.
 142 After immersion, each leaf was sealed in a standard Petri dish, with its petiole wrapped in a
 143 moistened cotton ball. The plates were incubated in an artificial climate chamber (RQX-250,
 144 Shanghai Yuejin Medical Devices Co., Ltd., Shanghai, China) at $28 \pm 2^\circ\text{C}$, $70 \pm 10\%$ RH, and
 145 12:12 (L:D) photoperiod. The specific method is as follows:

146 **Protein content determination:**

147 The 563 $\mu\text{g/mL}$ standard solution, working fluid, stop application solution and normal saline
 148 were purchased from the Jian Cheng Bioengineering Institute (Nanjing, China).

149 Sample processing: the animal tissue, was weighted and nine-times the volume of normal
 150 saline by weight was added [weight(g):volume (ml) = 1:9], the samples were then ground with
 151 liquid nitrogen to make a 10% tissue homogenate, which was then centrifuged at 2500 rpm for
 152 10 min (Sigma D-37520, Sigma-Aldrich, Germany). The supernatant was then diluted to 1%
 153 tissue homogenate with normal saline for experimentation.

154 The steps are described in the table 1:

155 After combining the solutions, they were placed at room temperature for 5 min, and measured
 156 colorimetrically at 562 nm, (L5S UV spectrophotometer, Shanghai Yidian Analytical Instrument
 157 Co., Ltd., Shanghai, China). Double-distilled water served as the blank control.

158

159 The protein concentration was determined as follows:

$$160 \quad \text{Protein } (\mu\text{gprot/mL}) = \frac{\text{Measure OD} - \text{Blank OD}}{\text{Standard OD} - \text{Blank OD}} \times \text{Standard solution } (563 \mu\text{g/mL}) \times \text{Sample dilution}$$

161 before determination

162

163 **SOD activity determination:**

164 Reagent one application solution, reagent two solution, reagent three solution, reagent four
 165 application solution, chromogen solution and normal saline were purchased from the Jian Cheng
 166 Bioengineering Institute, Nanjing.

167 Sample processing: the sample processing was as described in the protein content
 168 determination step above.

169 The steps are described in the table 2:

170 After combining the solutions, they were placed at room temperature for 10 min, and
 171 measured colorimetrically at 550 nm. Double-distilled water served as the blank control.

172 SOD activity was determined as follows:

$$173 \quad \text{SOD } (\text{U/mgprot}) = \frac{\text{Control OD} - \text{Measure OD}}{\text{Control OD}} \div 50\% \times \frac{\text{Total volume of reaction solution}}{\text{Sample size (mL)}} \div \text{Protein concentration}$$

174 of the sample to be tested (mgprot/mL)

175

176 **POD activity determination:**

177 Reagent one solution, reagent two application solution, reagent three application solution,
178 reagent four solution and normal saline were purchased from the Jian Cheng Bioengineering
179 Institute, Nanjing.

180 Sample processing: the sample processing was as described in the protein content
181 determination step above.

182 The steps are described in the table 3:

183 The solutions were combined and centrifuged at 3500 rpm for 10 min (Sigma D-37520,
184 Sigma-Aldrich, Germany), following which the supernatant was measured colorimetrically at
185 420 nm. Double-distilled water served as the blank control.

186 POD activity was determined as follows:

187
$$\text{POD (U/mgprot)} = \frac{\text{Measure OD} - \text{Blank OD}}{12 \times 1} \times \frac{\text{Total volume of reaction solution}}{\text{Sample size (mL)}} \div \text{Reaction time (30}$$

188 min) \div Protein concentration of the sample to be tested (mgprot/mL) \times 1000

189

190 **CAT activity determination:**

191 Reagent one solution, reagent two solution, reagent three solution, reagent four solution and
192 normal saline were purchased from the Jian Cheng Bioengineering Institute, Nanjing.

193 Sample processing: the sample processing was as described in the protein content
194 determination step above.

195 The steps are described in the table 4:

196 After combining the solutions, they were measured colorimetrically at 405 nm. Double-
197 distilled water served as the blank control.

198 CAT activity was determined as follows:

199
$$\text{CAT (U/mgprot)} = (\text{Control OD} - \text{Measure OD}) \times 271 \times \frac{1}{60 \times 0.05} \div \text{Protein concentration of the}$$

200 sample to be tested (mgprot/mL)

201

202 **CarE activity determination:**

203 The working fluid and normal saline were purchased from the Jian Cheng Bioengineering
204 Institute, Nanjing.

205 Sample processing: the sample processing was as described in the protein content
206 determination step above, except that the tissue homogenate was centrifuged at 12000 rpm for 4
207 min.

208 The steps were as follows:

209 ① The spectrophotometer was preheated for at least 30 min and the wavelength was adjusted to
210 450 nm. The machine was blanked with double-distilled water.

211 ② The working fluid was preheated at 37 °C for at least 30 min.

212 ③ Blank tube: 5 μL of distilled water was added to a blank glass cuvette, to which 1000 μL of
 213 preheated working solution was sequentially added to a 1 mL glass cuvette. The solution was
 214 rapidly mixed, and light absorption A_1 and A_2 was measured at 450 nm 10 s and 190 s,
 215 $\Delta A_{\text{Blank tube}} = A_2 - A_1$.

216 ④ Measuring tube: 5 μL of supernatant was sequentially added to a 1 mL glass cuvette, 1000 μL
 217 of preheated working solution, and rapidly mixed, and light absorption of A_3 and A_4 were
 218 measured at 450 nm, $\Delta A_{\text{Measuring tube}} = A_4 - A_3$.

219 $\text{CarE (U/mgprot)} = (\Delta A_{\text{Measuring tube}} - \Delta A_{\text{Blank tube}}) \times V \div (\text{Cpr} \times V_{\text{Sample}}) \div T$

220 V: total volume of the reaction solution, 1.005 mL;

221 Cpr: protein concentration of the sample to be tested (mgprot/mL);

222 V_{Sample} : adding of supernatant volume to the reaction system (mL), 0.005 mL;

223 T: catalytic reaction time (min), 3 min.

224

225 **AchE activity determination:**

226 1 $\mu\text{mol/ml}$ standard application solution, substrate buffer, chromogen application solution,
 227 inhibitor solution, transparent solution and normal saline were purchased from the Jian Cheng
 228 Bioengineering Institute, Nanjing.

229 Sample processing: the sample processing was as described in the protein content
 230 determination step above.

231 The steps are described in the table 5:

232 After combining the solutions, they were placed at room temperature for 15 min and measured
 233 colorimetrically at 412 nm. Double-distilled water served as the blank control.

234 AchE activity was determined as follows:

235 $\text{AchE (U/mgprot)} = \frac{\text{Measure OD} - \text{Control OD}}{\text{Standard OD} - \text{Blank OD}} \times \text{standard concentration (1 } \mu\text{mol/mL)} \div$

236 Protein concentration of the sample to be tested (mgprot/mL)

237

238 **GST activity determination:**

239 Matrix fluid, reagent two application solution, anhydrous alcohol, GSH standard application
 240 solution, 20 $\mu\text{mol/ml}$ GSH standard solution, reagent three application solution, reagent four
 241 application solution and normal saline were purchased from the Jian Cheng Bioengineering
 242 Institute, Nanjing.

243 Sample processing: the sample processing was as described in the protein content
 244 determination step above.

245 The steps are described in the table 6 and 7, below:

246 Enzymatic reaction (table 6):

247 The solutions were combined and centrifuged at 3500 rpm for 10 min (Sigma D-37520,
 248 Sigma-Aldrich, Germany). The supernatant was then used in the chromogen reaction.

249 Chromogen reaction (table 7):

250 The solutions were combined and placed at room temperature for 15 min, following which
251 they were measured colorimetrically at 412 nm. Double-distilled water served as the blank
252 control.

253 GST activity was determined as follows:

$$254 \text{ GST (U/mgprot)} = \frac{\text{Control OD} - \text{Measure OD}}{\text{Standard OD} - \text{Blank OD}} \times \text{standard concentration (20 } \mu\text{mol/mL)} \times$$

255 Reaction system dilution factor (6 times) \div Reaction time (10 min) \div [Sample volume (0.1 mL) \times
256 Protein concentration of the sample to be tested (mgprot/mL)]

257

258 **Determination of weight, and water and fat content of the *B. tabaci* nymphs after** 259 **infestation with *L. lecanii* JMC-01**

260 Tomato leaves with 3rd-instar *B. tabaci* nymphs exposed to 1.0×10^8 conidia/mL or the control
261 treatment ($w = 0.05\%$ Tween-80). The treated and control leaves were placed in similar Petri
262 dishes. Following this method was used, the same Petri dish method as above was then used.

263 The treatment and control group were selected one hundred 3rd-instar nymphs for
264 experimentation after 0 h, 12 h, 24 h, 36 h, 48 h, 60 h and 72 h, respectively. First determining
265 the total fresh weight of 100 nymphs prior to infection (Mettler Toledo LE204E/02 electronic
266 balance), the nymphs were dried by placing each batch at 60°C for 48 h in an electrothermal
267 blowing dry box (Shanghai Yiheng Technology Co., Ltd., Shanghai, China), and weighed in a
268 similar method as for the determination of dry weight (dry mass, DM).

269 Water content (WC) was determined using the formula $WC = (FW - DM) / FW \times 100\%$, where
270 DW is the dry mass determined as explained above, and FW is the fresh weight determined as
271 above.

272 Lipid extraction was performed with the dried nymphs. The dried nymphs were grinded under
273 liquid nitrogen in a centrifuge tube. One mL of chloroform isoamyl alcohol (24:1) and 0.5 mL of
274 methanol (99.99%) was added to each tube, mixed, and then centrifuged at 4500 rpm for 10 min.
275 The supernatant was discarded. The precipitate was extracted again with 1 mL of chloroform
276 isoamyl alcohol (24:1) and 0.5 mL of methanol (99.99%) by centrifugation at 4500 rpm for 10
277 min. The final remaining precipitate was dried in an oven at 60°C for 48 h to determine the
278 constant dry mass (LDM).

279 Fat content (FC) was determined using the formula $FC = (DM - LDM) / DM \times 100\%$, where
280 DM is the dry mass determined as explained above, and LDM is the constant dry mass
281 determined after lipid extraction.

282 There were three replicates per treatment and time point, and 100 nymphs per replicate.

283

284 **Data analysis**

285 Excel 2010 (Microsoft Corporation, Albuquerque, NM, USA) was used to process all the data.

286 All results are expressed as the mean \pm standard deviation (SD). Statistical analysis of the data
287 was performed using one-way analysis of variance (ANOVA) with SPSS version 21.0 (SPSS,

288 IBM Corp., Armonk, NY, USA). Multiple comparisons of the means were performed using

289 Duncan's (D) tests at a significance level of $P = 0.05$. All figures were produced using Origin 8.0.

290 EndNote X9 was used for managing citations.

291

292 **Results**

293 **Morphological characteristics of the *B. tabaci* nymphs**

294 Fig. 1 shows the morphological characteristics of *B. tabaci* under *L. lecanii* JMC-01 infection as
295 observed under a microscope (Leica Microsystems Wetzlar GmbH). The surface is covered with
296 hyphae.

297

298 **Mortality of the *B. tabaci* nymphs**

299 Fig. 2 indicates the cumulative mortality induced by *L. lecanii* JMC-01 to each *B. tabaci*
300 immature stage. The cumulative corrected mortality of the nymph instars was as follows (from
301 high to low): 2nd instar > 3rd instar > 1st instar > 4th instar > egg. The 2nd- and 3rd-instar nymphs were
302 most affected, with corrected cumulative mortality percentages of 82.22% and 75.55%,
303 respectively.

304

305 **The initial dose of *L. lecanii* JMC-01 affects the 3rd-instar *B. tabaci* nymphs**

306 As indicated in Fig. 3, increasing doses of *L. lecanii* JMC-01 (from 1×10^4 to 1×10^8 conidia/mL)
307 also increased the corrected cumulative mortality of the 3rd-instar nymphs, reaching a maximum
308 of 75.55% at 1×10^8 conidia/mL after 6 d.

309

310 **Protective and detoxifying enzyme activity determination**

311 The highest activity of SOD (43 U/mg prot) was detected on the 2nd day, reaching 1.1-fold that
312 of the control (Fig. 4). The highest activities of POD and CAT were 20 U/mg prot and 6.3 U/mg
313 prot on the 3rd day, respectively, and reached 2.4-fold and 1.4-fold that of the control level (Fig.
314 5, Fig. 6). Following this, the activities of protective enzymes decreased. The lowest activities of
315 SOD, POD, and CAT were 30 U/mg prot, 8.5 U/mg prot, and 1.3 U/mg prot on the 5th day,
316 respectively (Fig. 4, Fig. 5, Fig. 6).

317

318 The highest activities of CarE and AchE were 10.5 U/mg prot and 0.32 U/mg prot. These levels
319 were observed on the 3rd day and were 2.2-fold and 4.3-fold that of the control level, respectively
320 (Fig. 7, Fig. 8). The highest GST activity was 64 U/mg prot on the 2nd day and was 2.7-fold that
321 of the control level (Fig. 9). After the 3rd day, the activities of detoxifying enzymes decreased,
322 and the lowest activities of CarE, AchE, and GST respectively reached 3.5 U/mg prot, 15 U/mg
323 prot, and 0.05 U/mg prot on the 5th day (Fig. 7, Fig. 8, Fig. 9).

324

325 **Determination of the weight and water and fat contents of the of *B. tabaci* nymphs**

326 The lowest changes in weight were observed at 24-36 h. At 72 h, the weight of the infected
327 group was 0.78-fold that of the control (Fig. 10).

328 The water content of *B. tabaci* continuously decreased after infection with *L. lecanii*. At 72 h,
329 the water contents of the infected and control groups were lowest reaching 56% and 66%,

330 respectively (Fig. 11).

331 Until 36 h after infection, the changes in fat content were not significantly different from the
332 control level. At 72 h, the fat content of the infected and control groups was the lowest, reaching
333 13% and 20.5%, respectively (Fig. 12).

334

335 Discussion

336 The fungus penetrated the insect epidermis via the germ tubes and appressoria, following which
337 the conidia invaded the nymphs and began to enter the haemocoel. Ultimately, the hyphae
338 covered the host surface and had colonized the body cavity (Zhou et al., 2017). Previously, *L.*
339 *lecanii* caused over 90% mortality of vegetable pest, such as aphids, *Plutella xylostella*
340 (Keppanan et al., 2018; Saruhan, 2018; Sugimoto et al., 2003). In this study, mortality increased
341 greatly during the first 5 d of infection, with the maximum mortality is 82.22% being reached on
342 the 6th day. Accordingly, the activities of detoxification and protective enzymes were lowest on
343 the 5th day, indicating that as the infected nymphs of *B. tabaci* neared death on the 5th day, their
344 enzyme activity was reduced.

345 Insects are protected from the stresses of adverse conditions by various physical barriers,
346 including a cuticular exoskeleton, peritrophic membrane, and an immune system that reduces
347 pathogen infection (Chen and Lu, 2017). These fungi stimulate the stress responses of the insect
348 detoxification system and the protective enzyme system under adverse conditions by changing
349 the function of ion channels (Zhang et al., 2017). The major components of the antioxidant
350 defense system of insects include the antioxidant enzymes SOD, CAT, and POD (Li et al.,
351 2016b). When insects are stimulated by exogenous compounds, SOD converts the superoxide
352 radical O_2^- into H_2O_2 . Then, POD and CAT convert the H_2O_2 into H_2O . The imbalance between
353 oxidative stress and antioxidant responses contributes to disease and the death of insect hosts
354 (Felton and Summers, 1995).

355 Our study showed that, after infection of *B. tabaci* by *L. lecanii*, the activities of SOD, CAT,
356 and POD initially increased but then decreased thereafter, and the maximum activities protective
357 enzymes were observed on the 2nd day or 3rd day. Previous studies (Yang et al., 2015; Ye et al.,
358 2018; Zhou et al., 2017) indicated agricultural insects by entomogenous fungus, the activities of
359 SOD, CAT, and POD initially increased but then decreased. The increased activity of SOD, CAT,
360 and POD effectively preventing the formation of more toxic substances such as hydroxyl radicals
361 and helped increase the resistance of *B. tabaci*. Under *L. lecanii* infection, ROS and other toxic
362 substances stimulated an immune system response in *B. tabaci*. To resist the adverse
363 environmental influence and maintain normal physiological activities, the enzyme activities
364 sharply increased. However, the internal spread of the pathogen led to the destruction of the
365 internal tissue structure of the insect and subsequent collapse of the immune system. In addition,
366 the ROS scavenging system might not have been able to remove the excessive quantity of free
367 radicals, leading to reduced enzyme activity and the death of the insect (Li et al., 2016a). So, the
368 activities of SOD, CAT, and POD were decreased on the 5th day. GSTs participate in
369 detoxification metabolism and catalyze a combination of toxic substances with glutathione

370 and also promote the excretion of toxic chemicals and pathogenic substances (Mathews et al.,
371 2002; Schama et al., 2016). CarEs can catalyze the hydrolysis of ester bonds, and their major
372 physiological functions include lipid metabolism, detoxification metabolism of exogenous
373 compounds and biochemical regulatory functions (Guo et al., 2015). AchE is a target for
374 organophosphorus and carbamate insecticides (Ding et al., 2001). Some exogenous compounds,
375 such as pesticides and pathogenic fungi, can be altered by insect detoxification enzymes. This
376 suggests that *L. lecanii* can promote the detoxification metabolism of *B. tabaci*, which is
377 beneficial for the discharge of exogenous toxicants. With the increase in the level of *B. tabaci*
378 infection with *L. lecanii* exposure time, the exogenous toxicants overpowered the detoxification
379 metabolism, resulting in the eventual reduction in enzyme activities, and ultimately, insect death.
380 We found that the activities of CarEs, AchE, and GST initially increased but then decreased, and
381 the maximum activities of CarEs, AchE, and GST were observed on the 2nd day or 3rd day after
382 infection. Effects of *Isaria fumosorosea* Infection on Different Enzyme Activities in the Adult in
383 vivo of *Bemisia tabaci* indicated that the maximum activities of GSTs and CarE were observed
384 on the 48-60h (Tian et al., 2016a). Besides, these findings are similar to previous study (Liu et al.,
385 2013; Zhang et al., 2015). Insects infested with entomopathogenic fungi initially exhibit elevated
386 enzyme activities that decline as the fungal infection continues (Tian et al., 2016a). The
387 entomopathogenic fungus *L. lecanii* can be used to control *B. tabaci* nymphs, but the prevention
388 and control effect is slower than with chemical insecticides. However, the use of
389 entomopathogenic fungi in combination with insecticides to control pests could increase their
390 speed and efficacy (Purwar and Sachan, 2006).

391 A study of the pathogenicity and control potential of *Beauveria bassiana* on the onion fly
392 showed that the weight increment was smallest after 48 h. The water content and fat content
393 continued to decrease, and the water content and fat content of the infection level were 0.81-fold
394 and 0.69-fold that of the control level, respectively, at 72 h (Zhang, 2017). Screening of the
395 strains of the highly pathogenic *B. bassiana* on soybean pod borers and the assessment
396 biophysical and biochemical effects on their hosts indicated reductions in weight, water content,
397 and fat content (Tian, 2014). These studies corroborate our findings. In the present study, *B.*
398 *tabaci* nymphs infested with *L. lecanii* JMC-01 gradually lost vitality until death. This process
399 causes many physiological changes in the insects. Thus, *L. lecanii* could constitute a useful
400 alternative biopesticide for *B. tabaci* population management. Biocontrol can reduce insecticide
401 resistance and increase environmental and non-target organism safety.

402

403 Conclusions

404 We observed that *L. lecanii* JMC-01 affected the viability of the *B. tabaci* Q-biotype, by
405 inducing mortality, affecting the activities of protective and detoxifying enzymes, and by
406 significantly reducing the weight, and water and fat content. Thus, *L. lecanii* impacted the
407 physiological functioning of *B. tabaci* by directly acting on molecular targets and by indirectly
408 acting on detoxification and protective enzymes (Bantz et al., 2018). These results indicate that
409 this fungal strain could constitute an effective biological control for *B. tabaci* in agriculture.

410

411 **Acknowledgments**

412 We thank the private greenhouse owner for access to their greenhouse. We are grateful to Master
413 Kai Gao for providing the biotype of *B. tabaci* and we to Master Hui Wang for helping with the
414 formatting of this paper. We are grateful to two anonymous reviewers and Jasmine Janes for
415 their comments on an early version of the manuscript. We thank LetPub (www.letpub.com) for
416 its linguistic assistance during the preparation of this manuscript.

Note: times marked with different uppercase letters on the same line are significantly different ($P < 0.05$). The different lowercase letters indicate significant differences between the treatment and control groups ($P < 0.05$) at the same time point.

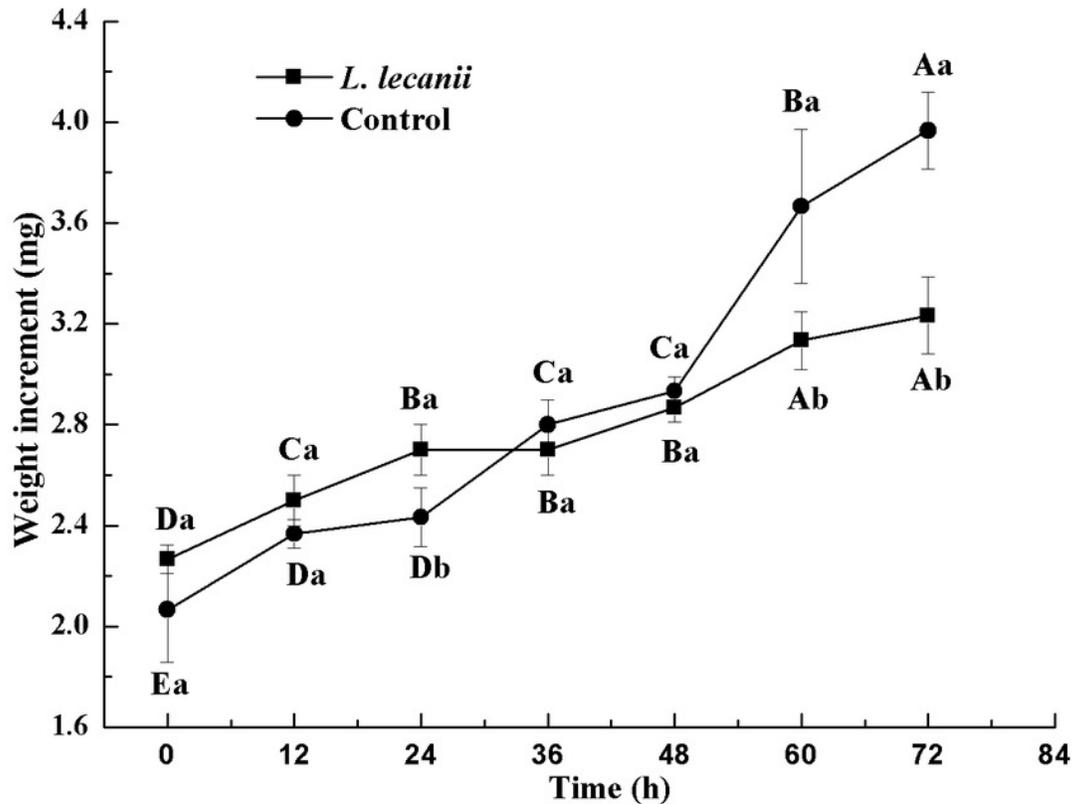

Figure 11

Changes in water content of the 3rd instar *B. tabaci* nymphs infected with *L. lecanii* JMC-01

Note: times marked with different uppercase letters on the same line are significantly different ($P < 0.05$). The different lowercase letters indicate significant differences between the treatment and control groups ($P < 0.05$) at the same time point.

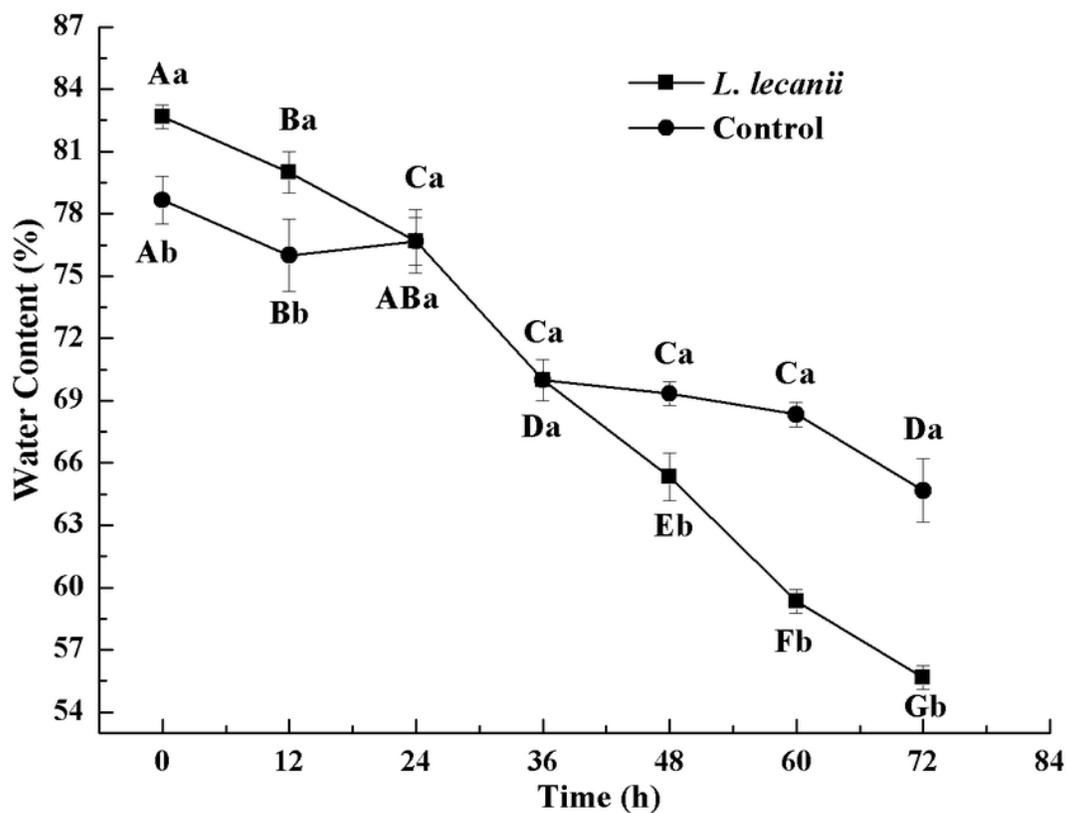

Figure 12

Changes in and fat content of the 3rd instar *B. tabaci* nymphs infected with *L. lecanii* JMC-01

Note: times marked with different uppercase letters on the same line are significantly different ($P < 0.05$). The different lowercase letters indicate significant differences between the treatment and control groups ($P < 0.05$) at the same time point.

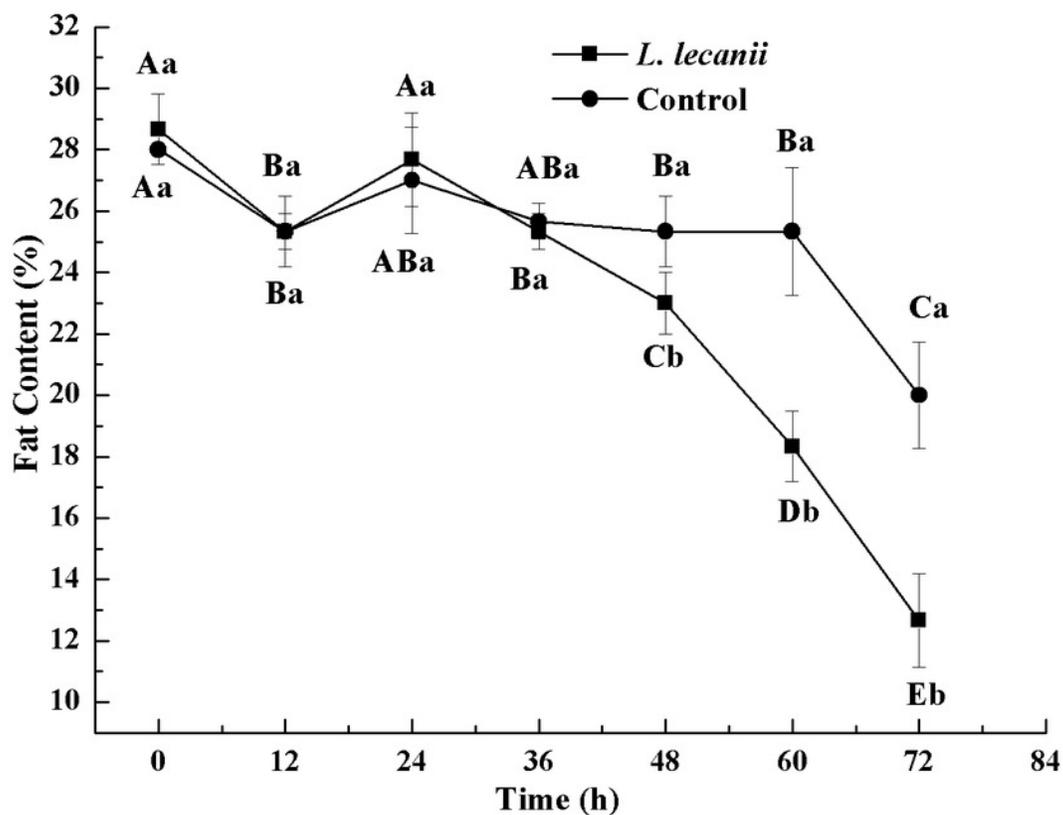

Table 1 (on next page)

The steps of protein content determination are described in the table 1

1 Table 1

	Blank tube	Standard tube	Measuring tube
Double distilled water (μL)	20		
563 $\mu\text{g}/\text{ml}$ standard solution (μL)		20	
Sample (μL)			20
Working fluid (μL)	250	250	250
Mix, set at 37 °C water bath for 30 min (digital thermostat water bath)			
Stop application solution (μL)	750	750	750

2

Table 2 (on next page)

The steps of SOD activity determination are described in the table 2

1 Table 2

Reagent	Measuring tube	Control tube
Reagent one application solution (mL)	1.0	1.0
Sample (mL)	0.1	
Double distilled water (mL)		0.1
Reagent two solution (mL)	0.1	0.1
Reagent three solution (mL)	0.1	0.1
Reagent four application solution (mL)	0.1	0.1
Mix, set at 37 °C water bath for 40 min (digital thermostat water bath)		
Chromogen solution (mL)	2	2

2

Table 3 (on next page)

The steps of POD activity determination are described in the table 3

1 Table 3

	Blank tube	Measuring tube
Reagent one solution (mL)	2.4	2.4
Reagent two application solution (mL)	0.3	0.3
Reagent three application solution (mL)	0.2	0.2
Double distilled water (mL)	0.1	
Sample (mL)		0.1
Set at 37 °C water bath for 30 min (digital thermostat water bath)		
Reagent four (mL)	1.0	1.0

2

Table 4(on next page)

The steps of CAT activity determination are described in the table 4

1 Table 4

	Control tube	Measuring tube
Sample (mL)		0.05
Reagent one solution (37°C preheat) (mL)	1.0	1.0
Reagent two solution (37°C preheat) (mL)	0.1	0.1
Mix, set at 37 °C water bath for 1 min (digital thermostat water bath)		
Reagent three solution (mL)	1.0	1.0
Reagent four solution (mL)	0.1	0.1
Sample (mL)	0.05	

2

Table 5 (on next page)

The steps of AchE activity determination are described in the table 5

1 Table 5

	Measuring tube	Control tube	Standard tube	Blank tube
Sample (mL)	0.1			
1 μ mol/mL standard application solution (mL)			0.1	
Double distilled water (mL)				0.1
Substrate buffer (mL)	0.5	0.5	0.5	0.5
Chromogen application solution (mL)	0.5	0.5	0.5	0.5
Mix, set at 37 °C water bath for 6 min (digital thermostat water bath)				
Inhibitor solution (mL)	0.03	0.03	0.03	0.03
Transparent solution (mL)	0.1	0.1	0.1	0.1
Sample (mL)		0.1		

2

Table 6 (on next page)

The steps of enzymatic reaction are described in the table 6

1 Table 6

	Measuring tube	Control tube
Matrix fluid (mL)	0.3	0.3
Sample (mL)	0.1	
Mix, set at 37 °C water bath for 10 min (digital thermostat water bath)		
Reagent two application solution (mL)	1	1
Anhydrous alcohol I(mL)	1	1
Sample (mL)		0.1

2

Table 7 (on next page)

The steps of chromogen reaction are described in the table 7

1 Table 7

	Blank tube	Standard tube	Measuring tube	Control tube
GSH standard application solution (mL)	2			
20 μ mol/mL GSH standard solution (mL)		2		
Supernatant (mL)			2	2
Reagent three application solution (mL)	2	2	2	2
Reagent four application solution (mL)	0.5	0.5	0.5	0.5
