

# Early archosauromorph remains from the Permo-Triassic Buena Vista Formation of northeastern Uruguay

Martin Ezcurra, Pablo Velozo, Melitta Meneghel, Graciela Piñeiro

The Permo-Triassic archosauromorph record is crucial to understand the impact of the Permo-Triassic mass extinction on the early evolution of the group and its subsequent dominance in Mesozoic terrestrial ecosystems. However, the Permo-Triassic archosauromorph record is still very poor in most continents and hampers the identification of global macroevolutionary patterns. Here we describe cranial and postcranial bones from the Permo-Triassic Buena Vista Formation of northeastern Uruguay that contribute to increase the meagre early archosauromorph record from South America. A basioccipital fused to both partial exoccipitals and three cervical vertebrae are assigned to Archosauromorpha based on apomorphies or a unique combination of characters. The archosauromorph remains of the Buena Vista Formation probably represent a multi-taxonomic assemblage composed of non-archosauriform archosauromorphs and a ‘proterosuchid-grade’ animal. This assemblage does not contribute in the discussion of a Late Permian or Early Triassic age for the Buena Vista Formation, but reinforces the broad palaeobiogeographic distribution of ‘proterosuchid grade’ diapsids in Permo-Triassic beds worldwide.

**14 Introduction**

15 Archosauromorpha is one of the major groups of diapsid reptiles, which includes around 10,000  
16 species of living birds and crocodilians (Clements, 2007) and all extinct species more closely  
17 related to these extant groups than to lepidosaurs (Dilkes, 1998). The oldest known  
18 archosauromorphs are represented by four nominal species restricted to Upper Permian rocks of  
19 Europe and Africa (e.g. *Protorosaurus speneri*, *Archosaurus rossicus*, *Eorasaurus olsoni*,  
20 *Aenigmastropheus parringtoni*; Meyer, 1830; Tatarinov, 1960; Sennikov, 1988, 1997; Gower &  
21 Sennikov, 2000; Gottmann-Quesada & Sander, 2009; Ezcurra, Scheyer & Butler, 2014). In the  
22 aftermath of the Permo-Triassic mass extinction, the archosauromorph fossil record is  
23 considerably more abundant and morphologically diverse, including members of Rhynchosauria,  
24 Prolacertiformes, Proterosuchidae and Archosauria (Charig & Reig, 1970; Charig & Sues, 1976;  
25 Carroll, 1976; Dilkes, 1998; Gower & Sennikov, 2000; Butler et al., 2011; Nesbitt, 2011;  
26 Ezcurra, Butler & Gower, 2013). The Permo-Triassic (latest Permian-earliest Triassic)  
27 archosauromorph record is crucial to understand the impact of the Permo-Triassic mass  
28 extinction on the group and their subsequent dominance in Mesozoic terrestrial ecosystems.  
29 However, the Permo-Triassic archosauromorph record is currently null or very meagre in several  
30 continents (e.g. South America, North America, Australia, Antarctica) (Camp & Banks, 1978;  
31 Thulborn, 1979, 1986; Colbert, 1987; Smith et al., 2011; Ezcurra, Butler & Gower, 2013;  
32 Ezcurra, Scheyer & Butler, 2014; Ezcurra, 2014). In particular, the South American Permo-  
33 Triassic archosauromorph record is remarkably scarce, being restricted to isolated postcranial  
34 bones from the Early Triassic Sanga do Cabral Formation of southern Brazil (Dias-da-Silva,  
35 1998; Langer & Schultz, 1997; Langer & Lavina, 2000; Da-Rosa et al., 2009; Dias-da-Silva &  
36 Da-Rosa, 2011 – the archosauriform *Koilamasuchus gonzalezdiazii* from the Quebrada de los  
37 Fósiles Formation of central-western Argentina [Bonaparte, 1981; Ezcurra, Lecuona &  
38 Martinelli, 2010] was recently redated as Middle-Late Triassic [Ottone et al., 2014]). Here, we

39 increase the South American early archosauromorph record with the description of cranial and  
40 postcranial bones from the Permo-Triassic Buena Vista Formation of northeastern Uruguay.

41 *Geological and palaeontological setting*

42 The Buena Vista Formation crops out in northeastern Uruguay and consists of red-  
43 brownish sandstones, intercalated with thin layers of red-brownish mudstones and  
44 intraformational conglomerates deposited under continental fluvial conditions (Bossi & Navarro,  
45 1991; Goso et al., 2001; Piñeiro & Ubilla, 2003). Most of the fossils collected from the Buena  
46 Vista Formation are found in the intraformational conglomerates and correspond to isolated  
47 bones to occasionally articulated partial skeletons. The tetrapod fossil content of the Buena Vista  
48 Formation represents the Colonia Orozco Local Fauna and includes laidleriid (*Uruyiella*  
49 *liminea*), mastodonsaurid, rhinesuchid-like and dvinosaurian temnospondyls (Marsicano, Perea  
50 & Ubilla, 2000; Piñeiro, 2004; Piñeiro Marsicano & Lorenzo, 2007; Piñeiro, Marsicano &  
51 Damiani, 2007; Piñeiro et al., 2007; Piñeiro, Ramos & Marsicano, 2012), procolophonoid  
52 parareptiles (i.e. *Pintosaurus magnidentis*; Piñeiro, 2004; Piñeiro, Rojas & Ubilla, 2004),  
53 probable varanopid and sphenacodontid synapsids (Piñeiro et al., 2003, 2013), and basal  
54 archosauromorphs (present study). The age of the Buena Vista Formation is poorly constrained  
55 because of the absence of index taxa and the presence of taxa that are documented in either Late  
56 Permian or earliest Triassic assemblages. Therefore, the age of this formation has been  
57 substantially debated. The Buena Vista Formation has been considered a lateral equivalent of the  
58 Sanga do Cabral Formation of southern Brazil based on lithostratigraphic similarities (Andreis,  
59 Bossi & Montardo, 1980; Bossi & Navarro, 1991). The Brazilian unit is considered late  
60 Induan–early Olenekian in age because of the presence of the index taxon *Procolophon* (Dias-da-  
61 Silva, Modesto & Schultz, 2006) and, as a result, the same age has been assigned to the Buena  
62 Vista Formation (Bossi & Navarro, 1991). However, subsequent authors have suggested an older

63 age for the Buena Vista Formation, being closer to the Permo-Triassic boundary or even within  
64 the Late Permian based on its tetrapod fossil content (Piñeiro & Ubilla, 2003; Piñeiro et al., 2003;  
65 Piñeiro, 2004; Piñeiro, Rojas & Ubilla, 2004; Piñeiro Marsicano & Lorenzo, 2007; Piñeiro,  
66 Marsicano & Damiani, 2007; **Piñeiro et al., 2007**; Piñeiro, Ramos & Marsicano, 2012). In  
67 particular, the description of varanopid synapsids would favour a Permian age (Piñeiro et al.,  
68 2003), but recent authors have casted doubts on these assignments and concluded that there is no  
69 compelling evidence to support a Permian age over an Early Triassic one (Dias-da-Silva,  
70 Modesto & Schultz, 2006). Here, we will consider the Buena Vista Formation as Permo-Triassic  
71 in age, taking into account recent studies that placed the Colonia Orozco Local Fauna as a  
72 transitional assemblage that could contain the Permo-Triassic boundary (see Piñeiro, Ramos &  
73 Marsicano, 2012).

98 *Materials.* FC-DPV 2641: co-ossified basioccipital and exoccipitals (Figs. 1, 2D–F, 3A, B); FC-  
99 DPV 2640: anterior cervical vertebra (Fig. 4A–B); FC-DPV 2637: middle cervical vertebra (Fig.  
100 5); FC-DPV 2639: middle or posterior cervical vertebra (Fig. 4C–G).

101 *Horizon and Locality.* Locality close to Colonia Orozco town, intraformational conglomerates of  
102 the Buena Vista Formation (Colonia Orozco Local Fauna, Permo-Triassic age, see geological and  
103 palaeontological setting), Cerro Largo County, northeastern Uruguay.

104 **Description**

105 *Braincase.* FC-DPV 2641 (Fig. 1; Table 1) is represented by an almost complete, slightly  
106 weathered basioccipital fused to the distal end of both exoccipitals. The presence of exoccipitals

107 (Fig. 1: exo) is mainly inferred because the ventrolateral borders of the foramen magnum (which  
108 are preserved in FC-DPV 2641) are formed by these bones in other amniotans, such as basal  
109 synapsids (e.g. Romer & Price, 1940), parareptiles (e.g. *Leptoleuron lacertinum*: Spencer, 2000;  
110 *Hypsognathus fennieri*: Sues et al., 2000) and archosauromorphs (e.g. *Azendohsaurus*  
111 *madagaskarensis*: UA 7-20-99-653; '*Chasmatosaurus*' *yuani*: IVPP V2719; *Doswellia*  
112 *kaltenbachi*: USNM 214823; *Chanaresuchus bonapartei*: MCZ 4037). In addition, there is a  
113 weak trace of suture between the basioccipital and the right exoccipital. The fusion between the  
114 exoccipitals and basioccipital occurs through ontogeny in several groups of amniotans, including  
115 basal diapsids (e.g. *Youngina capensis*: TM 3603, Evans, 1987; *Gephyrosaurus bridensis*: Evans,  
116 1980; *Mesosuchus browni*: SAM-PK-6536, Dilkes, 1998) and basal synapsids (e.g.  
117 *Secodontosaurus obtusidens*: Romer & Price, 1940; Reisz, Berman & Scott, 1992) (Fig. 2). The  
118 presence of this condition in FC-DPV 2641 and the well ossified occipital condyle probably  
119 indicate that this specimen did not belong to, at least, an early juvenile.

120 The occipital condyle of FC-DPV 2641 is poorly posteriorly projected as a result of a  
121 reduced occipital neck (Fig. 1: oc), resembling the condition in several basal diapsids (e.g.  
122 *Araeoscelis gracilis*: Vaughn, 1955; *Gephyrosaurus bridensis*: Evans, 1980; *Mesosuchus broomi*:  
123 SAM-PK-6536; *Proterosuchus alexanderi*: NMQR 1484; *Prolacerta broomi*: BP/1/2675;  
124 *Archeopelta arborensis*: CPEZ-239a, Desojo, Ezcurra & Schultz, 2011), parareptiles (e.g.  
125 *Hypsognathus fennieri*: Sues et al., 2000) and sphenacodont pelycosaurs (Romer & Price, 1940;  
126 Reisz, Berman & Scott, 1992). The occipital condyle is semi-spherical in overall shape, as occurs  
127 in archosauromorphs. Part of the posterior surface of the occipital condyle is flat, resembling the  
128 condition in the archosauromorphs *Mesosuchus broomi* (SAM-PK-6536) and *Prolacerta broomi*  
129 (BP/1/2675), and some basal synapsids (e.g. *Secodontosaurus obtusidens*: Reisz, Berman &  
130 Scott, 1992) (Fig. 2). The occipital condyle possesses a shallow, sub-circular notochordal pit  
131 immediately below the ventral border of the foramen magnum (Figs. 1E: np, 3A, B). The shape

132 and position of this pit closely resembles that of *Youngina capensis* (Gardner et al., 2010),  
133 *Proterosuchus alexanderi* (NMQR 1484), ‘*Chasmatosaurus*’ *yuani* (IVPP V2719) and some  
134 basal synapsids (e.g. *Dimetrodon*: Romer & Price, 1940; *Secodontosaurus obtusidens*: Reisz,  
135 Berman & Scott, 1992) (Figs. 2, 3: np). The articular surface of the occipital condyle is delimited  
136 laterally by an anteroposteriorly concave recessed surface that forms a slightly constricted  
137 occipital neck in ventral view (Fig. 1C, D: rs). This recessed surface is delimited anteriorly by a  
138 posteroventrally facing surface that belongs to the lateral flange of the basioccipital body (Figs.  
139 1–3: lf). These lateral flange is well developed, resembling the condition in *Prolacerta broomi*  
140 (BP/1/2675), *Proterosuchus* spp. (BSPG 1934 VII 514; NMQR 880, 1484) and  
141 ‘*Chasmatosaurus*’ *yuani* (IVPP V2719), and may have overlapped at least partially the ventral  
142 ramus of the opisthotic in posterior view (Fig. 3E: lf). The occipital condyle is only differentiated  
143 from the ventral surface of the main body of the basioccipital by a gentle, transverse change in  
144 slope at the median line, resembling the condition in several amniotans (e.g. *Youngina capensis*:  
145 Gardner et al., 2010; *Prolacerta broomi*: BP/1/2675; *Proterosuchus alexanderi*: NMQR 1484;  
146 *Secodontosaurus obtusidens*: Reisz, Berman & Scott, 1992).

147 The ventral surface of the basioccipital, immediately anterior to the occipital condyle, is  
148 slightly anteroposteriorly concave and lacks the median tuberosity present in *Garjainia prima*  
149 (Gower & Sennikov, 1996). The basioccipital region of the basal tubera is almost completely  
150 preserved, but their ventral surfaces are weathered off (Figs. 1–3: bt). These structures are well  
151 developed and ventrally directed, resembling the condition in some basal archosauromorphs (e.g.  
152 *Proterosuchus* spp.: BSPG 1934 VII 514; NMQR 880, 1484; *Fugusuchus hejiapanensis*: Gower  
153 & Sennikov, 1996) and some basal synapsids (e.g. *Dimetrodon*: Romer & Price, 1940; *Haptodus*  
154 *garnettensis*: Laurin, 1993). By contrast, the main axis of the basioccipital portion of the basal  
155 tubera is usually lateroventrally directed in most archosauromorphs, such as *Mesosuchus broomi*  
156 (SAM-PK-6536), *Azendohsaurus madagascarensis* (UA 7-20-99-653), *Prolacerta broomi*

157 (BP/1/2675), *Sarmatosuchus otschevi* (PIN 2865/68), ‘*Chasmatosaurus*’ *yuani* (IVPP V2719),  
158 *Erythrosuchus africanus* (NHMUK R3592), *Euparkeria capensis* (SAM-PK-5867), *Archeopelta*  
159 *arborensis* (CPEZ-239a) and *Chanaresuchus bonapartei* (PULR 07, MCZ 4037). The basal  
160 tubera are completely separated from each other at their bases, as also occurs in several diapsids  
161 (e.g. *Youngina capensis*: Gardner et al., 2010; *Gephyrosaurus bridensis*: Evans, 1980;  
162 *Mesosuchus broomi*: SAM-PK-6536; *Prolacerta broomi*: BP/1/2675; *Proterosuchus* spp.: BSPG  
163 1934 VII 514; NMQR 880, 1484; *Euparkeria capensis*: SAM-PK-5867; *Chanaresuchus*  
164 *bonapartei*: PULR 07, MCZ 4037). By contrast, in some other archosauromorphs the basal  
165 tubera are connected with each other by a transverse osseous lamina (e.g. *Azendohsaurus*  
166 *madagaskarensis*: UA 7-20-99-653; *Trilophosaurus buettneri*: Spielmann et al., 2008;  
167 ‘*Chasmatosaurus*’ *yuani*: IVPP V2719; *Fugusuchus hejiapanensis*: Gower & Sennikov, 1996;  
168 *Erythrosuchus africanus*: NHMUK R3592). In ventral view, the basal tubera are parallel to each  
169 other and to the sagittal plane of the basioccipital. The ventral surface of the basioccipital,  
170 between both basal tubera, is transversely concave and lacks the sub-circular foramen present in  
171 ‘*Chasmatosaurus*’ *yuani* (IVPP V2719) and some specimens of *Proterosuchus* (NMQR 880).

172 The lateral surface of the basioccipital is subdivided into dorsolaterally and lateroventrally  
173 facing surfaces. Both surfaces meet each other in an obtuse angle in posterior view at the apex of  
174 the lateral flange of the bone. The dorsolaterally facing surface is flat and probably participated  
175 of the medial wall of the metotic foramen (Fig. 1C, E: wmf). The ventrolaterally facing surface is  
176 damaged on the left side of the bone (Fig. 2E: ds), but well preserved on the right side. The  
177 ventrolaterally facing surface possesses a complex topology and is subdivided by a diagonal,  
178 posteroventrally-to-anterodorsally oriented ridge (Fig. 1: dr). The facet for reception of the  
179 ventral ramus of the opisthotic is situated posterodorsally to this ridge (Fig. 1C: fvro). This facet  
180 is posterodorsally-to-anteroventrally slightly concave and occupies a large portion of the lateral  
181 surface of the basioccipital. The size and shape of this facet suggest the presence of a robust

182 ventral ramus of the opisthotic, probably resembling the condition in basal archosauriforms (e.g.  
183 *Proterosuchus* spp.: BSPG 1934 VII 514; NMQR 880, 1484; '*Chasmatosaurus*' *yuani*: IVPP  
184 V2719; *Garjainia prima*: PIN 951/60). The surface anteroventral to the diagonal ridge is more  
185 deeply anteroposteriorly concave than the facet for the ventral ramus of the opisthotic and is  
186 delimited anteriorly by the facet for the parabasisphenoid (Fig. 1: fpbs). The presence of smooth  
187 cortical bone on this deeply concave surface indicates that probably it was a non-articulating  
188 surface and may have been part of the medial wall of the passage of the pseudolagenar recess  
189 (Fig. 1: mwpr). The pseudolagenar recess is present in *Prolacerta broomi*, *Euparkeria capensis*,  
190 several proterosuchian-grade archosauriforms and the poposauroid *Xilosuchus sapingensis*  
191 (Gower & Sennikov, 1996).

192 The anterior surface of the basioccipital possesses a slightly transversely convex facet for  
193 articulation with the parabasisphenoid (Fig. 1: fpbs). This articular facet extends also onto the  
194 anterodorsal surface of the basioccipital, immediately lateral to the floor of the endocranial  
195 cavity. The floor of the endocranial cavity is flat and possesses an anteroposteriorly long median  
196 longitudinal ridge, which is restricted to the anterior half of the basioccipital (Fig. 1B, E: mlr),  
197 resembling the condition in some procolophonids (e.g. *Leptoleuron lacertinum*: Spencer, 2000),  
198 synapsids (e.g. *Haptodus garnettensis*: Laurin, 1993) and diapsids (e.g. *Youngina capensis*:  
199 Gardner et al., 2010; *Gephyrosaurus bridensis*: Evans, 1980). The floor of the endocranial cavity  
200 of *Prolacerta broomi* possesses a pair of longitudinal ridges that delimit a shallow, median  
201 groove along most of the dorsal surface of the basioccipital (BP/1/2675).

202 The trace of suture between the right exoccipital and basioccipital indicates that the  
203 exoccipitals did not contact each other, at least, extensively on the floor of the endocranial cavity  
204 (Fig. 3A, B). The foramen/foramina for the exit of the hypoglossal and glossopharyngeal cranial  
205 nerves (CN XI–XII) are not preserved.

206 *Anterior cervical vertebra*. FC-DPV 2640 (Fig. 4 A-B; Table 2) is interpreted as an anterior  
207 postaxial cervical vertebra because of its strong anteroposterior elongation and a facet for  
208 articulation with the rib (only the base of the left structure is preserved) placed next to the  
209 anterior margin of the neural arch. The anterior end of the centrum is damaged. The posterior  
210 surface of the centrum is concave and seems to be slightly bevelled, possibly to receive a small  
211 intercentrum. The vertebra is possibly not notochordal. The centrum is approximately 3.6 times  
212 longer than tall, a ratio that closely resembles the condition in the third and fourth cervical  
213 vertebrae of moderately long-necked basal archosauromorphs, such as *Protorosaurus speneri*  
214 (BSPG 1995 I 5, cast of WMSN P47361), *Prolacerta broomi* (BP/1/2675) and *Macrocnemus*  
215 *bassanii* (PIMUZ T2472, T4355, T4822). By contrast, the anterior cervical vertebrae of other  
216 basal archosauromorphs are proportionally shorter (e.g. *Boreopricea*, PIN 3708/1: 1.92-2.00;  
217 *Jesairosaurus lehmani*, ZAR 07: <2.00; *Mesosuchus*, SAM-PK-5882, fourth cervical: 2.01;  
218 *Trilophosaurus buettneri*, Spielmann et al. [2008: appendix 10]: 1.84-2.50). The ventral surface  
219 of the centrum possesses a low and conspicuous median longitudinal keel. This keel extends  
220 along the entire preserved ventral surface of the centrum and becomes lower anteriorly. The  
221 centrum is slightly transversely compressed at mid-length and lacks a lateral fossa. The lateral  
222 surface of the centrum possesses a thin, longitudinal ridge that extends posteriorly from the base  
223 of the diapophysis to its posterior rim (Fig. 4A, B: arrow). A similar ridge is present in  
224 *Macrocnemus bassanii* (PIMUZ T4822), *Tanystropheus longobardicus* (PIMUZ T2818) and  
225 *Eorasaurus olsoni* (PIN 156/108, 109). A slightly developed longitudinal ridge is also present  
226 below the level of the diapophysis in some other basal diapsids (e.g. *Protorosaurus speneri*:  
227 Gottmann-Quesada & Sander, 2009). By contrast, the lateral surface of the centrum lacks a ridge  
228 in *Petrolacosaurus kansensis* (Reisz, 1981), *Gephyrosaurus bridensis* (Evans, 1981),  
229 *Trilophosaurus buettneri* (Spielmann et al., 2008), *Prolacerta broomi* (BP/1/2675) and  
230 *Proterosuchus alexanderi* (NMQR 1484). Only the base of the left facet for articulation with the

231 rib is preserved and is restricted to the anterior portion of the neural arch. The neurocentral suture  
232 is completely closed, indicating that the animal was not a juvenile at the moment of its death  
233 (Brochu, 1996; Irmis, 2007).

234 The zygapophyses lack their distal ends, but their preserved portions indicate that they  
235 were anteroposteriorly long, laterally divergent and sub-horizontal. As a result, the distal tips of  
236 the zygapophyses are well separated from the median line, resembling the condition in the  
237 anterior and middle cervicals of other basal archosauromorphs (e.g. *Trilophosaurus buettneri*:  
238 Spielmann et al., 2008). The neural arch possesses a very shallow depression lateral to the base of  
239 the neural spine (Fig. 4A, B: d), as occurs in *Prolacerta broomi* (BP/1/2675) and several other  
240 basal archosauromorphs. By contrast, the middle and posterior cervical vertebrae of at least some  
241 specimens of *Proterosuchus alexanderi* possess a better defined and deeper, sub-circular fossa  
242 lateral to the base of the neural spine (NMQR 1484). The neural spine is mostly complete, but its  
243 dorsal margin is damaged where it becomes very thin transversely (Fig. 4A, B: ns). As a result, it  
244 is interpreted that the neural spine should not have been much taller and preserves its general  
245 shape. The neural spine is dorsoventrally short and strongly elongated anteroposteriorly, as  
246 occurs in *Protorosaurus speneri* (BSPG 1995 I 5, cast of WMSN P47361), *Prolacerta broomi*  
247 (BP/1/2675), *Amotosaurus rotfeldensis* (SMNS 50830) and *Macrocnemus bassanii* (PIMUZ  
248 T2472, T4355, T4822), but contrasting with the taller and anteroposteriorly shorter neural spine  
249 of *Proterosuchus alexanderi* (NMQR 1484).

250 *Middle cervical vertebra.* The degree of anteroposterior elongation and the presence of a  
251 parallelogram-shaped centrum indicate that FC-DPV 2637 (Fig. 5; Table 2) belongs to a middle  
252 cervical vertebra after comparisons with other basal archosauromorphs (e.g. *Prolacerta broomi*:  
253 BP/1/2675; *Proterosuchus alexanderi*: NMQR 1484; *Trilophosaurus buettneri*: Spielmann et al.,  
254 2008). The vertebra is moderately elongated anteroposteriorly, in which the length of the centrum

255 is 2.68 times the height of its anterior articular surface. This ratio is slightly lower than that  
256 present in the middle cervical vertebrae of moderately long-necked basal archosauromorphs  
257 ( $>3.0$ , e.g. *Prolacerta broomi*: BP/1/2675; *Macrocnemus bessanii*: PIMUZ T4822; *Protorosaurus*  
258 *speneri*: BSPG 1995 I 5; *Eorasaurus olsoni*: PIN 156/108, 109). By contrast, the middle cervical  
259 vertebrae of *Trilophosaurus buettneri* (Spielmann et al., 2008), rhynchosauroids (e.g. *Mesosuchus*  
260 *browni*: SAM-PK-5882) and several basal archosauriforms (e.g. *Proterosuchus alexanderi*:  
261 NMQR 1484, *Erythrosuchus africanus*: NHMUK R3592; *Euparkeria capensis*: SAM-PK-586)  
262 are considerably proportionally anteroposteriorly shorter than FC-DPV 2637. The anterior  
263 articular facet of the centrum is more dorsally situated than the posterior one, resulting in a  
264 parallelogram-shaped centrum in lateral view (Fig. 5E–H), as occurs in basal archosauromorphs  
265 (Ezcurra, Scheyer & Butler, 2014). The centrum is amphicoelous and apparently not notochordal  
266 (i.e. lacks a continuous canal piercing the centrum), contrasting with the condition present in  
267 basal synapsids, parareptiles, early diapsids, basal lepidosauromorphs and the basal  
268 archosauromorph *Aenigmastropheus parringtoni* (Ezcurra, Scheyer & Butler, 2014). The anterior  
269 articular facet is subcircular (Fig. 5: afc) and possesses a notochordal pit (Fig. 5: np). The  
270 posterior facet is damaged and its overall contour cannot be determined (Fig. 5: pfc), but the  
271 preserved portion is congruent in morphology with that of the anterior facet. The ventral surface  
272 of the centrum is strongly transversely convex along its entire extension and possesses a subtle  
273 median longitudinal edge (Fig. 5K, L). The centrum is incipiently transversely compressed at  
274 mid-length. The lateral surface of the centrum is continuously dorsoventrally convex and lacks a  
275 lateral fossa. The vertebra possesses a single, anteroposteriorly elongated facet for articulation  
276 with the rib (Fig. 5: fr), as occurs in non-archosauromorph diapsids and tanystropheids (e.g.  
277 *Tanystropheus longobardicus*: Wild, 1973). This facet is restricted to the anterior half of the  
278 vertebra and situated approximately at level with the centrum-neural arch boundary. The  
279 neurocentral suture is completely closed.

280 In the neural arch, a posterior centrodiapophyseal lamina delimits a central  
281 infradiapophyseal fossa below the base of the transverse process (Fig. 5: pcdl). In addition, a  
282 tuberosity runs from the base of the transverse process towards the base of the postzygapophysis,  
283 but it does not reach the latter structure. This tuberosity and the posterior centrodiapophyseal  
284 lamina delimit a shallow subtriangular depression that is topologically equivalent to a  
285 postzygapophyseal centrodiapophyseal fossa. There are no anterior centrodiapophyseal and  
286 prezygodiapophyseal laminae in the neural arch, which may be a result of the relatively anterior  
287 position of the vertebra in the cervical series. The zygapophyses are horizontal and  
288 anteroposteriorly short, but extend slightly beyond the margins of the anterior and posterior  
289 articular facets of the centrum, respectively. The prezygapophyses are anterolaterally directed  
290 and, as a result, their distal tips are well separated from the median line (Fig. 5: prz), as occurs in  
291 the cervico-dorsal vertebrae of *Macrocnemus bessanii* (PIMUZ T482), *Tanystropheus*  
292 *longobardicus* (Wild, 1973) and *Trilophosaurus buettneri* (Spielmann et al., 2008). The articular  
293 surfaces of the zygapophyses are damaged and it is not possible to determine their morphology. A  
294 shallow and poorly defined, circular depression is present laterally to the base of the neural spine  
295 (Fig. 5: d), as occurs in at least some specimens of *Proterosuchus alexanderi* (NMQR 1484). The  
296 neural spine is moderately low and strongly anteroposteriorly elongated, being considerably  
297 anteroposteriorly longer than tall (Fig. 5: ns), closely resembling the condition in *Protorosaurus*  
298 *speneri* (BSPG 1995 I 5), *Macrocnemus bessanii* (PIMUZ T4822) and *Prolacerta broomi*  
299 (BP/1/2675). By contrast, in *Mesosuchus browni* (SAM-PK-5882), *Trilophosaurus buettneri*  
300 (Spielmann et al., 2008), *Proterosuchus fergusi* (BSPG 1934-VIII-514; GHG 231),  
301 *Sarmatosuchus otschevi* (PIN 2865/13-19), *Erythrosuchus africanus* (NHMUK R3592),  
302 *Garjainia prima* (PIN 2394/5-13, 5-16) and *Euparkeria capensis* (SAM-PK-586) the neural  
303 spines are taller than long. The neural spine possesses an anterior overhang that extends  
304 anteriorly beyond the base of the spine (Fig. 5: ao), as occurs in *Protorosaurus speneri* (BSPG

305 1995 I 5), *Macrocnemus bessanii* (PIMUZ T4822), *Trilophosaurus buettneri* (Spielmann et al.,  
306 2008) and *Prolacerta broomi* (BP/1/2675). The distal margin of the neural spine possesses a low  
307 transverse thickening (Fig. 5: dt), but it does not form a spine table or a mammillary process. The  
308 same thickening on the distal margin of the neural spine is present in several other long-necked  
309 archosauromorphs (e.g. *Macrocnemus bessanii*: PIMUZ T4822; *Prolacerta broomi*: BP/1/2675).  
310 The pre- and postspinal fossae are deep and transversely wide (Fig. 5: posf, prsf). The prespinal  
311 fossa is restricted to the base of the neural spine and the postspinal fossa extends onto most of the  
312 posterior surface of the spine, as usually occurs in other basal archosauromorphs (e.g. *Prolacerta*  
313 *broomi*: BP/1/2675).

314 *Middle–posterior cervical vertebra*. FC-DPV 2639 (Fig. 4C–G; Table 2) belongs to a middle or  
315 posterior cervical vertebra because the parapophyses are situated slightly above the mid-height of  
316 the centrum, adjacent to its anterior margin (Fig. 4D: pa), and the neural spine is  
317 anteroposteriorly short (Fig. 4D, E: ns). This vertebra is well-preserved, but moderately squeezed  
318 posteroventrally to the right side (Fig. 4G), the posterior articular facet of the centrum is damaged  
319 and most of the prezygapophyses, right diapophysis and neural spine are missing. The centrum is  
320 amphicoelous and apparently not notochordal. The centrum length represents 1.7 times the height  
321 of its anterior articular facet, being proportionally shorter than FC-DPV 2637 and resembling the  
322 ratio present in the middle-posterior cervical vertebrae of several basal archosauromorphs (e.g.  
323 *Aenigmastropheus parringtoni*: UMZC T836; *Eorasaurus olsoni*: PIN 156/109; *Trilophosaurus*  
324 *buechneri*: Spielmann et al., 2008; *Proterosuchus alexanderi*: NMQR 1484). The ventral surface  
325 of the centrum is transversely convex and lacks a median ventral keel. The centrum is slightly  
326 transversely compressed at mid-length. The anterior articular facet of the centrum is transversely  
327 broader than tall. The contour of the posterior facet cannot be determined because of damaging  
328 (Fig. 4G: pfc). The parapophyses are situated on laterally projected peduncles (Fig. 4C, D, F, G:

329 pa). The peduncle of the parapophysis possesses a moderately deep depression on its ventral  
330 surface. The facet of the parapophysis is semi-circular, with a mostly straight anterior margin,  
331 and mainly laterally facing, with a low anteroventral component. A sub-horizontal ridge extends  
332 posteriorly from the base of the parapophysis to the lateral surface of the centrum, but it does not  
333 reach the level of mid-length of the centrum (Fig. 4C, D: arrow). A similar ridge is also present in  
334 FC-DPV 2640 (Fig. 4A, B) and other basal archosauromorphs, such as *Macrocnemus bassanii*  
335 (PIMUZ T4822), *Tanytropheus longobardicus* (PIMUZ T2818), *Eorasaurus olsoni* (PIN  
336 156/108, 109) and *Garjainia prima* (PIN 2394/5-11, 5-13). The lateral surface of the centrum  
337 lacks a lateral fossa and the neurocentral suture is completely closed.

338 The diapophysis is mostly restricted to the anterior half of the neural arch (Fig. 4E: dp)  
339 and situated well above the centrum-neural arch boundary (Fig. 4C, D: dp). The diapophysis is  
340 moderately long and laterally developed, resembling the condition in other basal  
341 archosauromorphs (e.g. *Prolacerta broomi*: BP/1/2676). By contrast, in *Eorasaurus olsoni* and  
342 basal archosauriforms (e.g. *Proterosuchus alexanderi*: NMQR 1484) the diapophyses are better  
343 laterally developed than in FC-DPV 2639 (Ezcurra, Scheyer & Butler, 2014). The articular facet  
344 of the diapophysis is anteroposteriorly long, being considerably longer than tall. The neural arch  
345 possesses paradiapophyseal (Fig. 4C, D: pdl), posterior centrodiapophyseal (Fig. 4C, D: pcdl),  
346 prezygodiapophyseal (Fig. 4C–E: prdl) and postzygodiapophyseal laminae (Fig. 4C, D, G: podl),  
347 as also occurs in the posterior cervical and anterior dorsal vertebrae of some basal  
348 archosauromorphs (e.g. *Protorosaurus speneri*: BSPG 1995 I 5; *Tanytropheus longobardicus*:  
349 PIMUZ T2817; *Spinosuchus caseanus*: Spielmann et al., 2009) and several crown-archosaurs  
350 (Butler, Barrett & Gower, 2012). By contrast, *Prolacerta broomi* possesses only anterior  
351 centrodiapophyseal/paradiapophyseal and prezygodiapophyseal laminae (BP/1/2675), and  
352 *Proterosuchus* spp. possesses anterior centrodiapophyseal/paradiapophyseal (NMQR 1484) and,  
353 in some specimens, postzygodiapophyseal laminae (SAM-PK-11208). The four laminae of FC-

354 DPV 2639 delimit prezygapophyseal centrodiapophyseal, postzygapophyseal  
355 centrodiapophyseal, and centrodiapophyseal fossae. The zygapophyses are sub-horizontal and  
356 diverge slightly from the median line, resembling the condition in FC-DPV 2637 and FC-DPV  
357 2640. The postzygapophysis (Fig. 4C–E, G: poz) lacks epiphysis and its articular facet faces  
358 lateroventrally. There is a shallow fossa immediately lateral to the base of the neural spine (Fig.  
359 4E: d), as occurs in FC-DPV 2637, *Protorosaurus speneri* and *Proterosuchus alexanderi* (NMQR  
360 1484). The base of the neural spine is posteriorly displaced from the point of mid-length between  
361 the zygapophyses and subtriangular in cross-section, with an anteriorly oriented apex (Fig. 4C–E:  
362 ns). The postspinal fossa is transversely broad and deep, and extends dorsally onto the entire  
363 preserved posterior surface of the neural spine (Fig. 4G: posf).

#### 364 Taxonomic affinities

365 The partial braincase FC-DPV 2641 differs from those of parareptiles (e.g. *Procolophon*  
366 *trigoniceps*: Watson, 1914; *Leptoleuron lacertinum*: Spencer, 2000; *Owenetta kitchingorum*:  
367 Reisz & Scott, 2002; *Hypsognathus fenneri*: Sues et al., 2000) in the combination of a  
368 proportionally anteroposteriorly long basioccipital body (anteroposterior length of the body  
369 [excluding occipital condyle and anterior projection between posterolateral processes of the  
370 basisphenoid] versus maximum transverse width = 0.64; whereas the same ratio is 0.29 in  
371 *Leptoleuron lacertinum* [Spencer, 2000], 0.40 in *Owenetta kitchingorum* [Reisz & Scott, 2002],  
372 and 0.23 in *Hypsognathus fenneri* [Sues et al., 2000]), transversely narrow exoccipitals, vertical  
373 basal tubera and a semi-spherical occipital condyle. In addition, FC-DPV 2641 differs from basal  
374 synapsids in the presence of anteroposteriorly long basal tubera, being considerably longer than  
375 broad, and a sub-spherical occipital condyle (Fig. 2). By contrast, the occipital condyle of most  
376 pelycosaurs possesses an extensive planar posterior surface, resulting in a sub-quadrangular  
377 structure in ventral or lateral view (Fig. 2B; but a sub-spherical occipital condyle is also present

378 in *Varanops brevirostris*: Campione & Reisz, 2010), the basioccipital component of the basal  
379 tubera are strongly restricted posteriorly, being approximately as long as broad (Fig. 2C), and  
380 lacks an embayment to receive the massive footplate of the stape (e.g. *Dimetrodon limbatus*:  
381 Romer & Price, 1940; *Edaphosaurus pogonias*: Romer & Price, 1940; *Ophiacodon uniformis*:  
382 Romer & Price, 1940; *Aerosaurus wellesi*: Langston & Reisz, 1981; *Secodontosaurus obtusidens*:  
383 Reisz, Berman & Scott, 1992; *Haptodus garnettensis*: Laurin, 1993; *Varanops brevirostris*:  
384 Campione & Reisz, 2010). Furthermore, the Uruguayan partial braincase differs from Permo-  
385 Triassic cynodont synapsids (e.g. *Platycraenellus elegans*: Abdala, 2007) in the presence of a  
386 single occipital condyle. Within Diapsida, FC-DPV 2641 differs from non-archosauromorph taxa  
387 (e.g. *Araeoscelis gracilis*: Vaughn, 1955; *Gephyrosaurus bridensis*: Evans, 1980;  
388 *Planocephalosaurus robinsonae*: Fraser, 1982; *Youngina capensis*: Evans, 1987; Gardner et al.,  
389 2010) in the presence of a semi-spherical occipital condyle and vertical basal tubera.

390 The presence of a semi-spherical occipital condyle, considerably anteroposteriorly longer  
391 than broad and vertical basal tubera, and possibly a robust ventral ramus of the opisthotic is a  
392 combination of characters present only in Archosauromorpha, and allow the assignment of FC-  
393 DPV 2641 to this clade. No archosauromorph cranial remains have been described from other  
394 Permo-Triassic beds of South America (Dias-da-Silva, 1998; Da-Rosa et al., 2009; Dias-da-Silva  
395 & Da-Rosa, 2011), hampering comparisons with FC-DPV 2641. Similarly, we could not make  
396 comparisons with Late Permian archosauromorphs, such as *Archosaurus rossicus* and  
397 *Protorosaurus speneri*, because the knowledge of the braincase anatomy in these taxa is null or  
398 very limited (Sennikov, 1988; Gottmann-Quesada & Sander, 2009; Ezcurra, Scheyer & Butler,  
399 2014). Indeed, in only one specimen assigned to *Protorosaurus speneri* the occipital region is  
400 exposed but it is badly preserved and does not allow making proper comparisons (Fig. 3C). In  
401 particular, among archosauromorphs, FC-DPV 2641 shares with the South African species of  
402 *Proterosuchus* (i.e. *Proterosuchus fergusi*: BSPG 1934 VIII 514; *Proterosuchus alexanderi*:

403 NMQR 1484; *Proterosuchus goweri*: NMQR 880) and *Fugusuchus hejiapanensis* (Gower &  
404 Sennikov, 1996) the presence of vertical basal tubera (Fig. 3A, B, D, E). By contrast, in other  
405 basal archosauromorphs the basal tubera are lateroventrally oriented, being divergent from each  
406 other in posterior view (e.g. *Azendohsaurus madagaskarensis*: UA-7-20-99-653; *Trilophosaurus*  
407 *bueettneri*: Spielmann et al., 2008; *Mesosuchus browni*: SAM-PK-6536; *Howesia browni*: SAM-  
408 PK-5885; *Prolacerta broomi*: BP/1/2675; ‘*Chasmatosaurus*’ *yuani*: IVPP V2719; *Sarmatosuchus*  
409 *otschevi*: PIN 2865/68; *Garjainia prima*: PIN 951/60; *Erythrosuchus africanus*: NHMUK  
410 R3592). In addition, FC-DPV 2641 and the South African species of *Proterosuchus* differ from  
411 *Fugusuchus hejiapanensis* in the presence of basal tubera not connected to each other at their  
412 base. FC-DPV 2641 seems to differ from *Proterosuchus* (e.g. *Proterosuchus alexanderi*: NMQR  
413 1484) in the presence of a broader contribution of the basioccipital to the floor of the endocranial  
414 cavity (Fig. 3). However, this possible difference should be taken with caution because of the  
415 strong degree of fusion between the exoccipitals and basioccipital in the Uruguayan specimen. In  
416 conclusion, the combination of features present in FC-DPV 2641 are consistent with those  
417 present in *Proterosuchus* and the presence of the vertical basal tubera is probably an apomorphy  
418 of a grade of basal archosauriforms, because *Fugusuchus hejiapanensis* has been recovered as a  
419 more crownward archosauriform than proterosuchids in a recent phylogenetic analysis (Ezcurra,  
420 Lecuona & Martinelli, 2010). Therefore, FC-DPV 2641 is interpreted as an indeterminate  
421 archosauromorph, possibly archosauriform (depending on the phylogenetic relationships of basal  
422 members of the clade that are currently in state of flux; Ezcurra, Butler & Gower, 2013), cf.  
423 Proterosuchidae.

424 The anterior cervical vertebra FC-DPV 2640 and middle cervical vertebra FC-DPV 2637  
425 are assigned to an archosauromorph diapsid because of the following combination of characters:  
426 probable non-notochordal and anteroposteriorly elongated centra, a sub-horizontal ridge on the  
427 lateral surface of the centra, a shallow fossa immediately lateral to the base of the neural spines,

428 and neural spines considerably anteroposteriorly longer than tall (Fig. 4). In addition, the centrum  
429 of FC-DPV 2637 is parallelogram-shaped in lateral view, a character that was found as a  
430 synapomorphy of Archosauromorpha (Ezcurra, Scheyer & Butler, 2014), and has an anterior  
431 overhang and a transversely thickened distal margin on the neural spine, features that occur  
432 together in the basal archosauromorphs *Macrocnemus bessanii* (PIMUZ T4822) and *Prolacerta*  
433 *broomi* (BP/1/2675). These anterior and middle cervical vertebrae differ from those of  
434 “pelycosaur” synapsids and araeoscelidian diapsids in the presence of a probable non-  
435 notochordal centrum and a lower and longer neural spine (Ezcurra, Scheyer & Butler, 2014).  
436 Among long-necked basal archosauromorphs, FC-DPV 2637 and FC-DPV 2640 differ from  
437 *Prolacerta broomi* and *Trilophosaurus buettneri* in the presence of a low longitudinal lateral crest  
438 that runs posteriorly from the base of the facet for articulation with the rib, from *Macrocnemus*  
439 *bessanii* in the absence of epiphyses (PIMUZ T4822), and from other tanystropheids in the  
440 presence of a proportionally anteroposteriorly shorter centrum (e.g. *Amotosaurus rotfeldensis*:  
441 SMNS 50830). Although the neural spines possess damaged distal margins, they seem to have  
442 been dorsoventrally short. As a result, they differ from *Protorosaurus speneri* (BSPG 1995 I 5),  
443 which possesses tall neural spines. The combination of characters observed in FC-DPV 2640 is  
444 consistent with that present in basal archosauromorphs, such as *Prolacerta broomi* (BP/1/2675),  
445 but FC-DPV 2637 differs from this species in the presence of proportionally anteroposteriorly  
446 shorter centrum, and a less developed anterior overhang on the neural spine. FC-DPV 2637 and  
447 FC-DPV 2640 differ from the protorosaur cervical vertebra described by Dias-da-Silva (1998)  
448 from the Sanga do Cabral Formation in being considerably anteroposteriorly shorter. However,  
449 these differences could be due to the position of the vertebrae in the cervical series and the  
450 possibility that they belong to closely related species cannot be ruled out. Finally, the probable  
451 presence of a single facet for articulation with the cervical rib in FC-DPV 2637 is a feature  
452 shared with non-archosauromorph diapsids (e.g. *Gephyrosaurus bridensis*: Evans, 1981;

453 *Planocephalosaurus robinsonae*: Fraser & Walkden, 1984) and tanystropheids (e.g. *Amotosaurus*  
454 *rotfeldensis*: SMNS 50830; *Tanystropheus longobardicus*: Wild, 1973; Nosotti, 2007). By  
455 contrast, more derived archosauromorphs possess distinct parapophyses and diapophyses in the  
456 postaxial cervicals (e.g. *Mesosuchus*: Dilkes, 1998; *Trilophosaurus buettneri*: Spielmann et al.,  
457 2008; *Prolacerta*: BP/1/2675). Accordingly, FC-DPV 2637 and FC-DPV 2640 are interpreted as  
458 indeterminate basal archosauromorphs, but at least FC-DPV 2637 might belong to a very basal  
459 member of the clade because of the presence of a single facet for the rib.

460 The middle-posterior cervical vertebra FC-DPV 2639 possesses a series of characters that  
461 were found as synapomorphies of Archosauromorpha or less inclusive clades within the group by  
462 Ezcurra, Scheyer & Butler (2014): a trapezoidal and probable non-notochordal centrum, and  
463 anterior centrodiapophyseal, posterior centrodiapophyseal, prezygodiapophyseal and  
464 postzygodiapophyseal laminae on the neural arch (Fig. 4C, D). The combination of characters  
465 observed in FC-DPV 2639 resembles that present in several disparate basal archosauromorphs  
466 (e.g. *Protorosaurus speneri*: BSPG 1995 I 5; *Tanystropheus longobardicus*: PIMUZ T2817;  
467 *Spinosuchus caseanus*: Spielmann et al., 2009). Nevertheless, FC-DPV 2639 differs from  
468 *Prolacerta broomi* and *Proterosuchus fergusi* in the presence of a posterior centrodiapophyseal  
469 lamina. FC-DPV 2639 cannot be properly compared with the protorosaur cervical vertebra from  
470 the Sanga do Cabral Formation (Dias-da-Silva, 1998) because the latter belongs to a more  
471 anterior element in the axial series. As a result, FC-DPV 2639 is interpreted as an indeterminate  
472 basal archosauromorph, but distinct from *Prolacerta* and proterosuchids.

### 473 Discussion

474 The presence of archosauromorphs in the Permo-Triassic Buena Vista Formation was previously  
475 reported by Piñeiro (2002) and Piñeiro & Ubilla (2003), but no detailed description or taxonomic

476 discussion have been provided so far. The cranial and postcranial remains described here increase  
477 the meagre archosauromorph record in Permo-Triassic rocks of South America.

478 The partial braincase with resemblances to *Proterosuchus* is particularly interesting  
479 because it probably reinforces the broad palaeobiogeographic distribution of proterosuchids  
480 during Permo-Triassic times (i.e. European Russia, China, South Africa, possibly Australia)  
481 (Ezcurra, Butler & Gower, 2013). However, we need to be cautious about this hypothesis because  
482 the specimen shows some differences that could not be properly compared with the Permian  
483 representatives of the group, such as the possible broad contribution of the basioccipital to the  
484 ventral margin of the foramen magnum (Fig. 3). The complete skull length of FC-DPV 2641 is  
485 estimated between 200–250 mm based on linear regressions of the total length of the skull versus  
486 the width and height of the occipital condyle, respectively, of a series of proterosuchid skulls  
487 from the *Lystrosaurus* Assemblage Zone of South Africa (N = 4: NMQR 880, 1484, BSPG 1934  
488 VIII 514, GHG 231; occipital condyle width:  $y = 0.0514x - 0.02115$ ,  $R^2=0.96$ ; occipital condyle  
489 height:  $y = 0.0295x + 2.8892$ ,  $R^2=0.80$ ). The skull length range recovered for FC-DPV 2641 falls  
490 in the 4<sup>th</sup> to 18<sup>th</sup> percentile of the South African proterosuchid sample (N = 14, total skull length  
491 ranges from 177 to 477 mm; Ezcurra and Butler, 2014). The presence of a medium-sized basal  
492 archosauromorph in the Permo-Triassic of South America is not unexpected because of the  
493 presence of relatively large proterosuchids in the latest Permian of Russia (*Archosaurus rossicus*)  
494 and relatively large basal archosauromorphs in the earliest Triassic of Antarctica (Smith et al.,  
495 2011), South Africa (*Proterosuchus fergusi*) and China ('*Chasmatosaurus*' *yuani*).

496 The archosauromorph partial braincase described here belongs to an individual  
497 considerably larger than those of the cervical vertebrae. Among the postcranial bones, the  
498 middle-posterior cervical vertebra (FC-DPV 2639) pertained to an animal larger than those of the  
499 anterior and middle-posterior cervical vertebrae (FC-DPV 2637, 2640), and the latter two  
500 vertebrae are similar in size to each other (Table 2: compare transverse width of the centra). We

501 could not find any autapomorphy or combination of features that might allow refer the cervical  
502 vertebrae to a single species. Conversely, the simultaneous occurrence of a proterosuchid-like  
503 partial braincase and a middle-posterior cervical vertebra with clear differences with  
504 proterosuchids support the hypothesis of a multi-taxonomic archosauromorph assemblage. The  
505 archosauromorph record of the Buena Vista Formation seems to bolster a Permo-Triassic age for  
506 the unit, as previously concluded by Piñeiro, Ramos & Marsicano (2012). Unfortunately, this  
507 archosauromorph assemblage does not help in the debate of a Permian or Triassic age for this  
508 unit because both basal archosauromorphs and early archosauriforms (e.g. proterosuchids) are  
509 present across the Permo-Triassic boundary (Ezcurra, Scheyer & Butler, 2014).

## 510 **Acknowledgments**

511 We thank the following curators, researchers and collection managers that provided access to  
512 specimens under their care for the purpose of this research: Bernhard Zipfel, Bruce Rubidge and  
513 Fernando Abdala (BP); Markus Moser and Oliver Rauhut (BSPG); William Simpson (FMNH);  
514 Ellen de Kock (GHG); Liu Jun and Corwin Sullivan (IVPP); Jessica Cundiff (MCZ); Ronan  
515 Allain (MNHN); Sandra Chapman and Lorna Steel (NHMUK); Elize Butler and Jennifer Botha-  
516 Brink (NM); Heinz Furrer and Torsten Scheyer (PIMUZ); Andrey Sennikov (PIN); Sergio Martin  
517 (PULR); Sheena Kaal and Roger Smith (SAM); Rainer Schoch (SMNS); Heidi Fourie (TM);  
518 Mathew Lowe and Jennifer Clack (UMZC); and Michael Brett-Surman and Hans-Dieter Sues  
519 (USNM). The research of MDE was supported by a grant of the DFG Emmy Noether Programme  
520 to RJB (BU 2587/3-1) and ANII\_FCE2011\_6450 supported the research of GP, MM and PV.

## 715 FIGURE CAPTIONS

716 **Figure 1.** Partial braincase (FC-DPV 2641) from the Late Permian–Early Triassic Buena Vista  
717 Formation (Uruguay) in (A) posterior; (B) anterior; (C) right lateral; (D) left lateral; (E) dorsal;  
718 and (F) ventral views. Abbreviations: bt, basal tubera; dr, diagonal ridge; ecf, endocranial floor;  
719 eo, exoccipital; fpbs, facet for the parabasisphenoid; fvro, facet for the ventral ramus of the  
720 opisthotic; lf, lateral flange of the basioccipital; mlr, median longitudinal ridge; mwpr, medial  
721 wall of the pseudolagenar recess; np, notochordal pit; oc, occipital condyle; rs, recessed surface;  
722 wmf, wall of the metotic foramen. Scale bar equals 5 mm.

723 **Figure 2.** Anatomical comparison between (A–C) the pelycosaur *Secodontosaurus obtusidens*  
724 (modified from Reisz, Berman & Scott, 1992) and (D–F) FC-DPV 2641 in (A, D) posterior, (B,  
725 E) left lateral, and (C, F) ventral views. Abbreviations: bo, basioccipital; bt, basal tubera; ds,  
726 damaged surface; eo, exoccipital; lf, lateral flange of the basioccipital; mwpr, medial wall of the  
727 pseudolagenar recess; np, notochordal pit; oc, occipital condyle; op, opisthotic; ps, parasphenoid;  
728 so, supraoccipital. Scale bars equal 10 mm.

729 **Figure 3.** Anatomical comparison between (A, B) FC-DPV 2641, (C) *Protorosaurus speneri*  
730 (modified from Gottmann-Quesada & Sander, 2009), and (D, E) a sub-adult specimen of  
731 *Proterosuchus alexanderi* (NMQR 1484) in occipital views. Abbreviations: XII?, possible exit of  
732 the hypoglossal cranial nerve; bo, basioccipital; bo?, possible basioccipital; bt, basal tubera; eo,  
733 exoccipital; eo?, possible exoccipital; fm, foramen magnum; fo, fenestra ovalis; lf, lateral flange  
734 of the basioccipital; mf, metotic foramen; mf?, possible metotic foramen; np, notochordal pit; p,  
735 parietal; plr, pseudolagenar recess; pp, paraoccipital process; so, supraoccipital; vrop, ventral  
736 ramus of the opisthotic. Scale bars equal 10 mm.

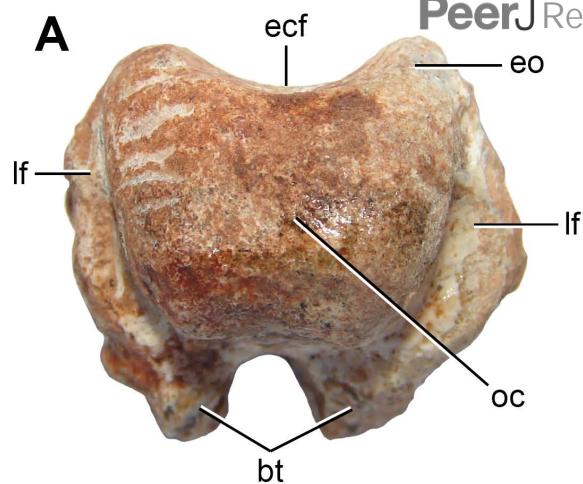

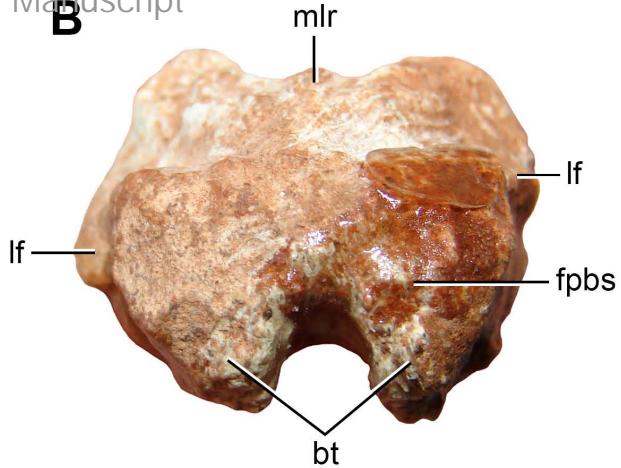

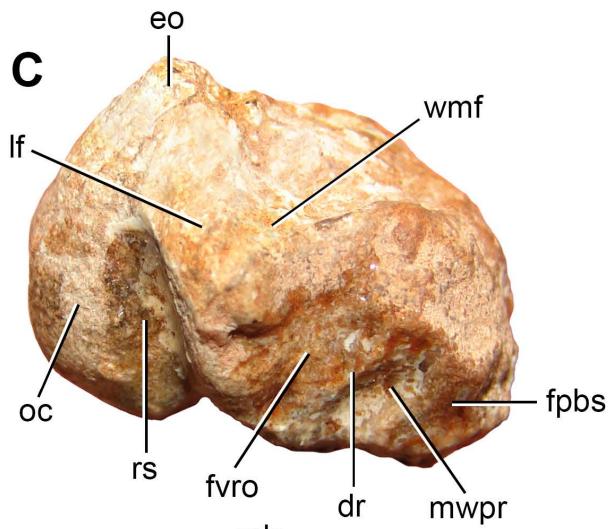

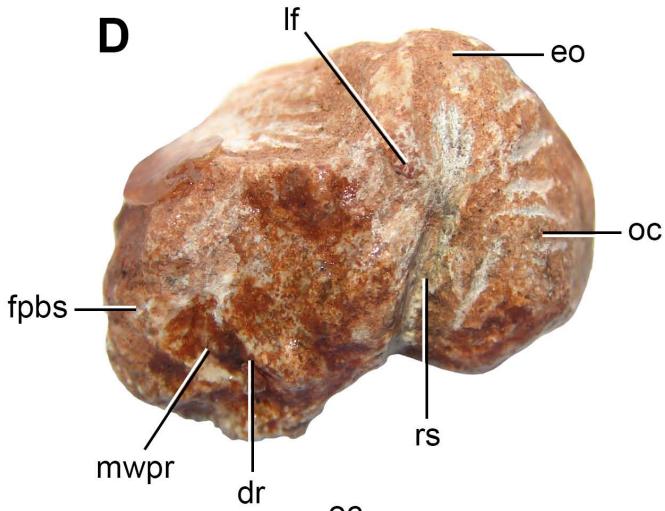

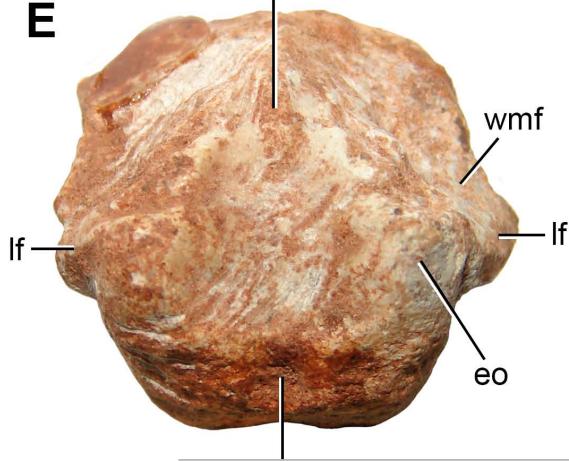

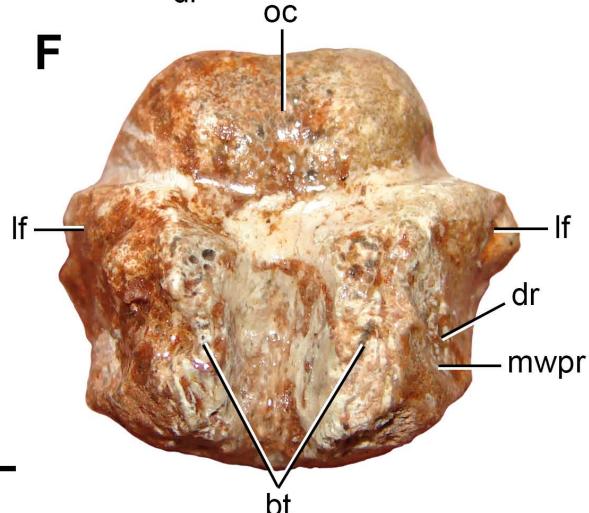

737 **Figure 4.** Photographs and interpretive drawings of (A–B) an anterior cervical vertebra (FC-DPV  
738 2640) and (C–G) a middle-posterior cervical vertebra (FC-DPV 2639) from the Late  
739 Permian–Early Triassic Buena Vista Formation (Uruguay) in (A–D) right lateral, (E) dorsal, (F)  
740 ventral, and (G) posterior views. The arrows indicate the longitudinal ridge on the lateral surface  
741 of the centrum. Abbreviations: d, depression; dp, diapophysis; ns, neural spine; pa, parapophysis;  
742 pcdl, posterior centrodiapophyseal lamina; pdl, paradiapophyseal lamina; pfc, posterior facet of  
743 the centrum; podl, postzygodiapophyseal lamina; posf, postspinal fossa; prdl,  
744 prezygodiapophyseal lamina; prz, prezygapophysis; poz, postzygapophysis. Scale bars equal 5  
745 mm.

746 **Figure 5.** Photographs and interpretive drawings of a middle cervical vertebra (FC-DPV 2637)  
747 from the Late Permian–Early Triassic Buena Vista Formation (Uruguay) in (A, B) anterior; (C,  
748 D) posterior; (E, F) right lateral; (G, H) left lateral; (I, J) dorsal; and (K, L) ventral views.  
749 Abbreviations: afc, anterior facet of the centrum; ao, anterior overhanging; d, depression; dt,  
750 distal thickening; fr, facet for the rib; nc, neural canal; np, notochordal pit; ns, neural spine; pcdl,  
751 posterior centrodiapophyseal lamina; pfc, posterior facet of the centrum; posf, postspinal fossa;  
752 poz, postzygapophysis; prsf, prespinal fossa; prz, prezygapophysis. Scale bars equal 5 mm.

## Figure 1

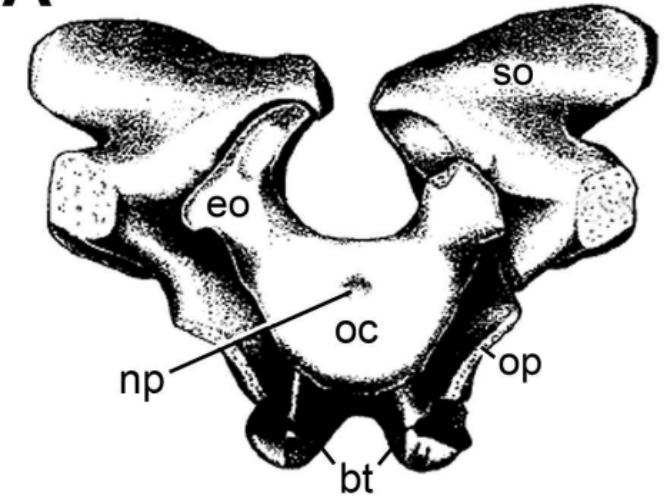

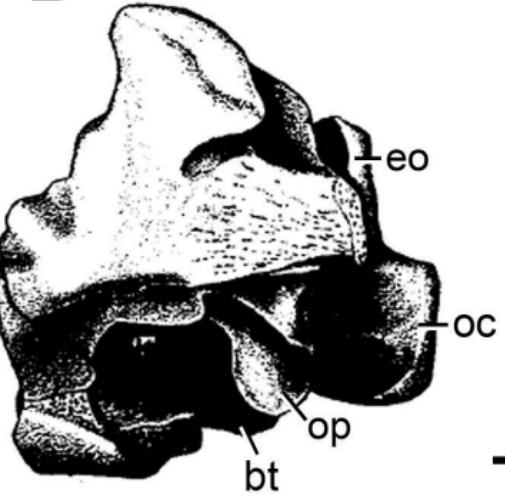

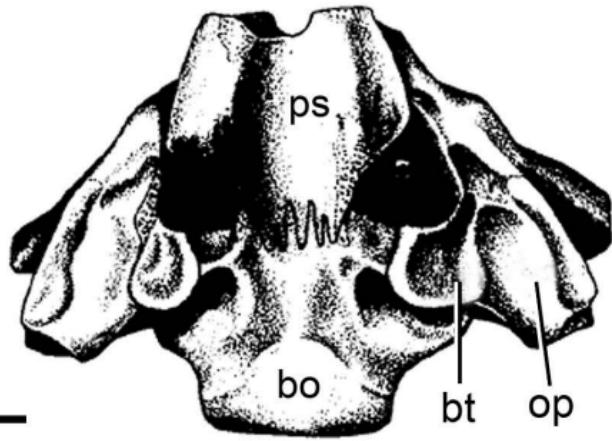

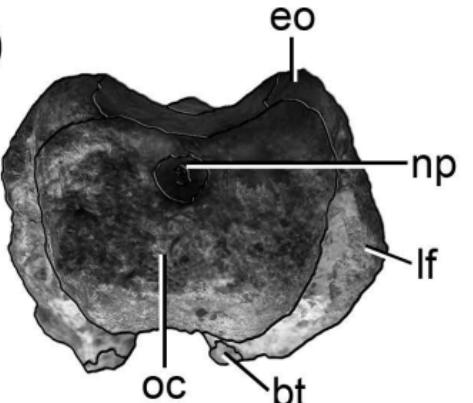

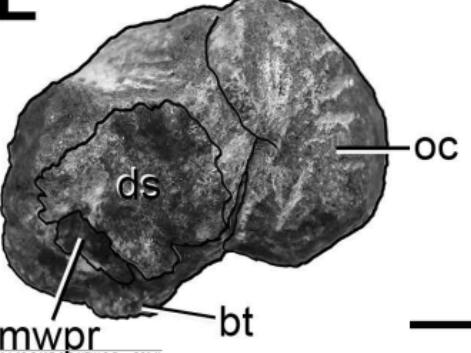

Partial braincase (FC-DPV 2641) from the Late Permian–Early Triassic Buena Vista Formation (Uruguay) in (A) posterior; (B) anterior; (C) right lateral; (D) left lateral; (E) dorsal; and (F) ventral views. Abbreviations: bt, basal tubera; dr, diagonal ridge; ecf, endocranial floor; eo, exoccipital; fpbs, facet for the parabasisphenoid; fvro, facet for the ventral ramus of the opisthotic; lf, lateral flange of the basioccipital; mlr, median longitudinal ridge; mwpr, medial wall of the pseudolagenar recess; np, notochordal pit; oc, occipital condyle; rs, recessed surface; wmf, wall of the metotic foramen. Scale bar equals 5 mm.

**Table 1**(on next page)

Table 1

**Table 1.** Measurements of the basioccipital+exoccipitals (FC-DPV 2641) in millimeters.

Values between brackets indicate incomplete measurements. Maximum deviation of the digital caliper is 0.02 mm but measurements were rounded to the nearest 0.1 millimeter.

Length of basioccipital	16.6
Width of basioccipital	(17.1)
Height of basioccipital	(13.6)
Occipital condyle height	9.0
Occipital condyle width	12.6
Occipital condyle length	5.3
Notochordal pit height	2.0
Notochordal pit width	2.3
Basal tuber length	8.5
Basal tuber width	4.2

**Table 2**(on next page)

Table 2

**Table 2.** Measurements of the anterior (FC-DPV 2640), middle (FC-DPV 2639), and middle-posterior (FC-DPV 2637) cervical vertebrae in millimeters. Values between brackets indicate incomplete measurements and between squared brackets indicate estimated measurements. The length along the zygapophyses is the maximum anteroposterior length between the anterior tips of the prezygapophyses and the posterior tips of the postzygapophyses. Maximum deviation of the digital caliper is 0.02 mm but measurements were rounded to the nearest 0.1 millimeter.

	FC-DPV 2640	FC-DPV 2637	FC-DPV 2639
Centrum length	(17.8)	12.6	12.1
Anterior facet of centrum width	-	4.4	[7.8]
Anterior facet of centrum height	-	4.7	[7.1]
Posterior facet of centrum width	4.8	(4.2)	(5.9)
Posterior facet of centrum height	(4.9)	4.7	(6.5)
Length along zygapophyses	(19.8)	(13.5)	(11.8)
Height of neural spine	(3.1)	5.8	-
Length of neural spine	(9.4)	8.9	4.7
Maximum height of vertebra	(13.2)	14.0	(12.2)
