Background. In 2018, Paraguay experienced a large dengue virus (DENV) outbreak. The primary objective of this study was to characterize dengue cases in the Central Department, where the majority of cases occur, and identify factors associated with DENV infection. **Methods.** Patients were enrolled from January-May 2018 if they presented with a suspected arboviral illness. Acute-phase specimens (≤ 8 days after symptom onset) were tested using rRT-PCR, a rapid diagnostic test for DENV nonstructural protein 1 (NS1) and anti-DENV IgM and IgG, and ELISA for IgG against NS1 from Zika virus (ZIKV). **Results.** 231 patients were enrolled (95.2% adults) at two sites: emergency care and an outpatient clinical site. Patients included 119 (51.5%) dengue cases confirmed by rRT-PCR (n=115, 96.6%) and/or the detection of NS1 and anti-DENV IgM (n=4, 3.4%). DENV-1 was the predominant serotype (109/115, 94.8%). Epidemiologically, dengue cases and non-dengue cases were similar, though dengue cases were less likely to reside in a house/apartment or report a previous dengue case. Clinical and laboratory findings associated with dengue included red eyes, absence of sore throat, leucopenia and thrombocytopenia. At an emergency care site, 26% of dengue cases (26/100) required hospitalization. In univariate analysis, hospitalization was associated with increased viral load, anti-DENV IgG, and thrombocytopenia. Among dengue cases that tested positive for IgG against ZIKV NS1, the odds of DENV NS1 detection in the acute phase were decreased 10-fold (OR 0.1, 0.0-0.3). **Conclusions.** Findings from a predominantly adult population demonstrate clinical and laboratory factors associated with DENV infections and the potential severity of dengue in this group. The combination of viral load and specific IgG antibodies warrant further study

as a prognostic to identify patients at risk for severe disease.

23 **Abstract**

24 **Background.** In 2018, Paraguay experienced a large dengue virus (DENV) outbreak. The
25 primary objective of this study was to characterize dengue cases in the Central Department,
26 where the majority of cases occur, and identify factors associated with DENV infection.

27

28 **Methods.** Patients were enrolled from January-May 2018 if they presented with a suspected
29 arboviral illness. Acute-phase specimens (≤ 8 days after symptom onset) were tested using rRT-
30 PCR, a rapid diagnostic test for DENV nonstructural protein 1 (NS1) and anti-DENV IgM and
31 IgG, and ELISA for IgG against NS1 from Zika virus (ZIKV).

32

33 **Results.** 231 patients were enrolled (95.2% adults) at two sites: emergency care and an
34 outpatient clinical site. Patients included 119 (51.5%) dengue cases confirmed by rRT-PCR
35 ($n=115$, 96.6%) and/or the detection of NS1 and anti-DENV IgM ($n=4$, 3.4%). DENV-1 was the
36 predominant serotype (109/115, 94.8%). Epidemiologically, dengue cases and non-dengue cases
37 were similar, though dengue cases were less likely to reside in a house/apartment or report a
38 previous dengue case. Clinical and laboratory findings associated with dengue included red eyes,
39 absence of sore throat, leucopenia and thrombocytopenia. At an emergency care site, 26% of
40 dengue cases (26/100) required hospitalization. In univariate analysis, hospitalization was
41 associated with increased viral load, anti-DENV IgG, and thrombocytopenia. Among dengue
42 cases that tested positive for IgG against ZIKV NS1, the odds of DENV NS1 detection in the
43 acute phase were decreased 10-fold (OR 0.1, 0.0-0.3).

44

45 **Conclusions.** Findings from a predominantly adult population demonstrate clinical and
46 laboratory factors associated with DENV infections and the potential severity of dengue in this
47 group. The combination of viral load and specific IgG antibodies warrant further study as a
48 prognostic to identify patients at risk for severe disease.

49 **Introduction**

50 Dengue is the commonest human arboviral disease worldwide, with an estimated 50-100 million
51 cases occurring annually throughout the tropics and subtropics (Stanaway et al. 2016; World
52 Health Organization 2009). Dengue results from human infection with one of four related
53 serotypes of dengue virus (DENV-1-4) (Guzman & Harris 2015). All four serotypes circulate in
54 the Americas and cause large outbreaks every 2-5 years (Dantes et al. 2014; Gordon et al. 2013;
55 Pan American Health Organization 2018). Paraguay reports among the highest annual incidence
56 rates of dengue in South America (Pan American Health Organization 2018). Since the
57 introduction of DENV-4 in 2012, all four serotypes have been detected in the country. Over the
58 past decade, DENV-1 has circulated in all but one year and has been predominant since 2015
59 (Dirección General de Vigilancia de la Salud & Ministerio de Salud Pública y Bienestar Social
60 2017; Pan American Health Organization 2018). Despite significant declines in dengue incidence
61 throughout the Americas following the 2015-2016 Zika virus (ZIKV) epidemic, Paraguay
62 experienced large numbers of dengue cases in 2016 and again in 2018 (Pan American Health
63 Organization 2018; Perez et al. 2019). These data suggest that arboviral epidemiology may be
64 relatively unique in Paraguay, which is located at the southern boundary of the DENV-endemic
65 region in the Americas (Bhatt et al. 2013; Stanaway et al. 2016; World Health Organization
66 2009). However, relatively little data has been published on dengue in the country, and the
67 majority of available data has come either from hospitalized pediatric cases or from international
68 studies with only a subset of patients from Paraguay (Halsey et al. 2012; Lovera et al. 2014;
69 Lovera et al. 2016; Rojas et al. 2016).

70

71 Symptomatic DENV infections classically present as an acute fever with myalgias and rash
72 (Guzman & Harris 2015; World Health Organization 2009). However, patients can develop a
73 wide array of signs and symptoms, which limits the accuracy of a clinical diagnosis based on
74 exam findings and results of routine laboratory testing (Gregory et al. 2010; Morch et al. 2017;
75 Potts & Rothman 2008; Waggoner et al. 2016b). In addition, dengue manifests differently among
76 children and adults, and factors associated with dengue cases and severe disease in a pediatric
77 population may not be applicable in older patients (Gregory et al. 2010; Hammond et al. 2005;
78 Kittigul et al. 2007). The differential diagnosis for dengue includes arboviral pathogens, such as
79 chikungunya virus (CHIKV) and Zika virus (ZIKV), and local endemic diseases, such as
80 leptospirosis, which may all cause an indistinguishable clinical picture (O. Silva et al. 2018;
81 Waggoner et al. 2016b). Accurate diagnosis in the acute phase relies upon the availability of
82 specific laboratory tests, which for DENV include molecular methods and nonstructural protein
83 1 (NS1) antigen detection. Anti-DENV IgM detection in acute-phase samples provides a
84 presumptive diagnosis (Peeling et al. 2010; World Health Organization 2009). As dengue can
85 progress to severe disease, including plasma leakage, hemorrhage, and shock, ideal testing
86 algorithms would not only detect DENV infections but also provide prognostic information.
87

88 The primary objective of the current study was to characterize DENV infections in the Central
89 Department of Paraguay and the metropolitan area of Asunción. This region annually accounts
90 for ~2/3 of dengue cases in Paraguay and also reported Zika cases in 2016. Multiplex molecular
91 testing, NS1 antigen detection and serological methods were implemented to confirm cases
92 identified using a broad clinical case definition. We then sought to evaluate factors associated
93 with dengue cases and the need for hospitalization in a predominantly adult patient population.

94

95 **Materials & Methods**

96

97 **Ethics statement.** The study protocol was reviewed and approved by the Scientific and Ethics
98 Committee of the Instituto de Investigaciones en Ciencias de la Salud, Universidad Nacional de
99 Asunción (IICS-UNA, IRB00011984), and the Emory University Institutional Review Board
100 (IRB00000569). Written informed consent was obtained from all subjects. Children older than
101 six years of age provided assent.

102

103 **Patient population and clinical samples.** Patients of all ages were enrolled from January to
104 May 2018 if they presented with an acute illness (≤ 8 days) defined by 2 or more of the
105 following: fever (measured or subjective), red eyes, rash, joint pain involving more than one
106 joint, and/or diffuse muscle pain. Patients with fever and no other localizing signs or symptoms
107 were included. Day 1 was defined as the first day of symptoms. Exclusion criteria included
108 dysuria or malodorous urine, cellulitis/skin abscess, vomiting and/or a productive cough. Patients
109 were enrolled at in the Emergency Care Clinic at Hospital Villa Elisa and at IICS-UNA, both
110 located in metro Asunción. The Emergency Care Clinic serves an ambulatory urgent care patient
111 population; patients may be assigned to observation at Hospital Villa Elisa or referred to an
112 inpatient facility that can provide a higher level of care. Serum was collected during the acute
113 visit, aliquoted and stored at -80°C until use. The results from hemograms, performed as part of
114 routine care, were obtained by chart review. Data was included in this study if the hemogram
115 was obtained on the day of the study visit ± 1 day.

116

117 **Molecular detection.** RNA was extracted from 140 μ L of serum into 60 μ L of elution buffer with
118 the QIAamp Viral RNA Mini Kit (Qiagen, Germantown, MD). All samples were tested for
119 ZIKV, CHIKV and DENV by real-time RT-PCR (rRT-PCR) using a validated and published
120 multiplex assay (the ZCD assay) as previously described (Waggoner et al. 2016a). DENV
121 serotype and viral load were determined with a DENV multiplex assay using a published
122 protocol (Waggoner et al. 2013b; Waggoner et al. 2013c). Samples that tested negative in the
123 ZCD assay were tested for RNase P to confirm successful extraction and the absence of
124 inhibitors (Waggoner et al. 2013a). Arboviral rRT-PCR testing was performed at IICS-UNA.
125

126 **Serological assays.** All serum samples were test for DENV NS1 antigen and anti-DENV IgM
127 and IgG using the STANDARD Q Dengue Duo assay (SD Biosensor, Suwon, South Korea).
128 Results were read initially at 15 or up to 20 minutes, according to manufacturer
129 recommendations. One hundred fifty-six samples were tested for anti-ZIKV IgG using the
130 ZIKVG.CE kit (Diagnostic Bioprobes, Milan, Italy), which detects antibodies directed against
131 the ZIKV NS1 antigen. Given a limited supply of anti-ZIKV IgG kits, a mixture of samples was
132 selected for testing. This included dengue cases (n=76) and non-dengue cases (n=80), as well as
133 include patients with anti-DENV IgG (n=58) and without (n=98). Assays were performed
134 according to manufacturer recommendations.
135

136 **Definitions.** Dengue cases were defined by either the detection of 1) DENV RNA in serum using
137 the ZCD assay with confirmation in the DENV multiplex assay, or 2) both NS1 and anti-DENV
138 IgM. This conservative definition was used to ensure the accuracy of dengue-case calls in the
139 absence of paired acute and convalescent sera for confirmatory serological testing. This

140 definition also allowed us to evaluate the performance of the STANDARD Q DENV NS1 assay,
141 for which there was no prior published data. The sensitivity and specificity of individual
142 diagnostics were calculated in reference to positive and negative cases from this composite
143 definition.

144

145 **Statistics.** Basic statistical analyses were performed using Excel software (Microsoft, Redmond,
146 WA). Univariate analyses and multiple linear regression analyses were performed using
147 GraphPad Prism, version 8.0.1 (GraphPad, San Diego, CA). Categorical variables were
148 compared using Fisher's exact test. Age, day of illness, and continuous laboratory variables were
149 compared by t test. Viral load comparisons were performed using non-parametric tests (Mann-
150 Whitney with 2 groups; Kruskal-Wallis for 3 or more groups). Binary logistic regression analysis
151 was performed using SPSS (IBM, Armonk, NY). Model fit was assessed by comparing -2 log
152 likelihood statistics.

153

154 **Results**

155 Between January and May 2018, we enrolled 231 patients who met inclusion criteria, including
156 119 (51.5%) dengue cases and 112 (48.5%) non-dengue cases. No acute cases of ZIKV or
157 CHIKV were detected. Of the dengue cases, 115 (96.6%) tested positive by rRT-PCR and 4
158 additional cases (3.4%) were positive for DENV NS1 and anti-DENV IgM (Table 1). All cases
159 tested positive by rRT-PCR through day-of-illness 6 (n=104), with rates of detection declining
160 on days 7 (7/10, 70%) and 8 (4/5, 80%; Fig. 1). For the NS1 assay, the overall sensitivity and
161 specificity were 71.4% and 96.4%, respectively (Table 1). Although there appeared to be an
162 increase in NS1 sensitivity over the first 5 days of illness, this was not statistically significant

163 (p=0.208, day 5 vs. day 1-2; Fig. 1). The overall sensitivity and specificity of anti-DENV IgM
164 detection were 26.1% and 93.8%, respectively. The sensitivity of IgM detection increased from
165 0% on days 1-2 to 90% on day 7 (p<0.001).

166

167 DENV serotype was determined in all 115 rRT-PCR-positive cases, with DENV-1 identified in
168 109/115 (94.8%) cases and 3 cases (2.6%) each of DENV-2 and DENV-4. No co-infections were
169 detected. DENV-1 serum viral loads negatively correlated with day of illness at presentation
170 (Fig. 2A), but too few data points were available for DENV-2 and -4 to draw meaningful
171 conclusions. DENV viral load was also associated with NS1 detection: viral loads were
172 significantly higher in samples with detectable NS1 (median 7.7 log₁₀ copies/mL, IQR 5.8-8.6)
173 compared to those in which NS1 was not detectable (median 5.6 log₁₀ copies/mL, IQR 3.6-7.2;
174 p<0.0001; Fig. S1).

175

176 Anti-DENV and anti-ZIKV IgG results were available for 156 patients, including 76 dengue
177 cases (48.7%). 58 patients (37.2%) tested positive for anti-DENV IgG and 49 (31.4%) tested
178 positive for anti-ZIKV IgG, with 32 patients (20.5%) positive for both. The viral load among
179 dengue cases declined in a stepwise manner among patients with anti-ZIKV IgG, anti-DENV
180 IgG, or both (Fig. 2B, p < 0.0001 for the trend). In a multivariable model that included day of
181 illness at presentation and patient age, DENV serum viral load was 1.3 log₁₀ copies/mL lower
182 among patients with detectable anti-DENV IgG compared to patients without anti-DENV IgG
183 (p<0.0001, Table S1). Similarly, serum viral load was 0.7 log₁₀ copies/mL lower among patients
184 with anti-ZIKV IgG directed against NS1 (p=0.047).

185

186 Among dengue cases, DENV NS1 detection was also associated with IgG status. Patients with
187 anti-DENV IgG were significantly less likely to have detectable NS1 [20/36 (55.6%) vs. 65/83
188 (78.3%); OR 0.3, 95% CI 0.1-0.8]. However, when we controlled for the detection of IgG against
189 ZIKV NS1, the OR for NS1 detection among dengue cases with anti-ZIKV IgG was 0.1 (95% CI
190 0.0-0.3) and the association with anti-DENV IgG was no longer significant (OR 1.0, 95% CI 0.3-
191 3.1; Table S2).

192

193 **Epidemiologic characteristics.** The epidemiologic characteristics of the patient population are
194 shown in Table 2. This was predominantly an adult population, with only 11 participants < 18
195 years of age at study entry (4.8%). Dengue cases occurred throughout the study period (Fig. S2)
196 and were similar to non-dengue cases for the majority of epidemiological variables analyzed.
197 Most patients reported living in a house or an apartment (157/188 for which data was available,
198 83.5%), but 31 patients reported “other” for housing without providing further detail. The odds
199 of dengue in this population were significantly higher than among patients with a different living
200 arrangement (OR 2.9, 95% CI 1.3-7.0). Only 10.6% of our patients (21/199) reported having
201 screens on their windows, though 79.2% of patients had air conditioning (156/197). The
202 percentage of dengue cases among patients with neither screens nor air conditioning (19/37,
203 51.4%) was similar to that of patients with screens, air conditioning, or both (79/161, 49.1%; OR
204 1.1, 95% CI 0.5-2.2).

205

206 A subset of patients self-reported having been vaccinated against yellow fever virus (YFV). The
207 odds of having a dengue case were lower among patients who had received the YFV vaccine
208 compared to those who had not (OR 0.6; 0.4-1.2), and more time had elapsed since vaccination

209 among dengue cases. However, these trends did not reach statistical significance ($p=0.15$).

210 Receipt of the YFV vaccine did not increase the need for hospitalization among dengue cases.

211

212 **Clinical presentation.** Patient symptoms at presentation are shown in Table 3. The majority of

213 patients met inclusion criteria with fever plus one additional symptom in the study definition,

214 most commonly muscle pain (198/225, 88.0%) and/or joint pain (172/221, 77.8%). Only 11

215 patients (4.8%) had fever and no other localizing sign or symptom (6 dengue cases), and 8

216 patients (3.5%) were enrolled that did not have fever (1 dengue case). Patients who reported red

217 eyes were significantly more likely to have dengue (OR 2.1; 95% CI 1.2-3.6) and those with a

218 sore throat were significantly less likely to have dengue (OR 0.5; 95% CI 0.3-0.8; Table 3).

219 Although a reported headache increased the odds of having dengue, this did not reach statistical

220 significance (OR 2.3; 95% CI 1.0-5.5), and headache was very common overall. Other symptoms

221 occurred with similar frequency in the two groups, and no combination of symptoms accurately

222 differentiated between dengue and non-dengue cases.

223

224 Hemogram results are also shown in Table 3. Patients with dengue had significantly lower

225 platelet and leucocyte counts relative to non-dengue cases (Fig. 3). Thrombocytopenia ($<150,000$

226 per μL) and leucopenia ($<4,000$ cells/ mm^3) were both significantly associated with DENV

227 infections (Table 3). However, patients with both findings were not at greater odds of having a

228 DENV infection (OR 8.9; 95% CI 3.4-23.0) than patients with leucopenia alone (OR 11.0, 95%

229 CI 5.1-22.2). Dengue cases had lower neutrophil and lymphocyte counts, but these occurred in

230 proportion to the decrease in leucocyte counts (data not shown).

231

232 **Hospitalization.** For the analysis of factors associated with hospitalization for dengue, we
233 focused on cases that presented to Hospital Villa Elisa, as only 1/19 dengue cases (5.3%) at
234 IICS-UNA required hospitalization. Of 100 dengue cases at Hospital Villa Elisa, 26 (26.0%)
235 were hospitalized and one patient died (Table 4). A number of clinical and laboratory findings
236 were associated with hospitalization in univariate analysis. Rash and bleeding were more
237 common among hospitalized cases. Admitted patients were significantly more likely to have
238 detectable anti-DENV IgG and IgG against both DENV and ZIKV (anti-NS1). Despite the
239 presence of anti-DENV IgG, viral load was significantly higher among admitted patients, but
240 there was no difference in NS1 detection. In multivariate analysis, the best-fit model for
241 predictors of hospitalization only included platelet count and day of illness, though the odds ratio
242 for day of illness did not reach significance (OR 1.3, 95% CI 0.9-1.8; Table S3).

243

244 **Discussion**

245 In the current study, we characterized a set of dengue cases in a primarily adult population that
246 presented to outpatient facilities in metro Asunción. Dengue is a major public health problem in
247 Paraguay, with adults accounting for a significant proportion of cases. At Hospital Villa Elisa,
248 58% of patients with an acute febrile illness were adults ≥ 20 years of age, and an additional 13%
249 of patients were aged 15-19. While studies have demonstrated that the clinical presentation of
250 dengue in adults may differ from that in children (Hammond et al. 2005; Kittigul et al. 2007;
251 Potts & Rothman 2008), less research has specifically evaluated factors that differentiate dengue
252 from other causes of an acute febrile illness in the adult population (Chadwick et al. 2006;
253 Gregory et al. 2010). All but one dengue case in our study presented with fever and a high
254 percentage of cases had headache, myalgia and/or arthralgia (Chadwick et al. 2006; Hammond et

255 al. 2005; Kittigul et al. 2007; Potts & Rothman 2008). However, these symptoms were common
256 among both dengue cases and non-dengue cases. The only two symptoms that were significantly
257 associated with dengue in our population were red eyes and the absence of a sore throat. Red
258 eyes have not been commonly associated with dengue (Chadwick et al. 2006), and the frequency
259 of this finding could make it difficult to differentiate dengue from Zika in regions where both
260 viruses are transmitted (Chadwick et al. 2006; O. Silva et al. 2018; Waggoner et al. 2016b). The
261 absence of a sore throat has been associated with dengue in a previous series (Gregory et al.
262 2010). However, this was only reported by 26.5% of our patients overall, which limits the utility
263 of this finding in clinical practice.

264

265 In contrast to clinical findings, the results of general laboratory studies differed significantly
266 between dengue cases and non-cases. Leucopenia and thrombocytopenia were associated with
267 dengue (ORs 11.0 and 4.0, respectively). However, patients with both findings did not have
268 higher odds of dengue than those with leucopenia alone, which may have resulted from temporal
269 differences in the development and resolution of these abnormalities (Biswas et al. 2012). The
270 nadir leucocyte counts occurred on days 5-6 after symptom onset, whereas platelet counts
271 demonstrated a consistent decline through day 8 (data not shown). Many factors were
272 significantly associated with hospitalization in univariate analyses but were also strongly
273 correlated with one another (viral load, antibody status, platelet count, day of illness). Given the
274 sample size, our ability to model all of these factors in logistic regression was limited, and
275 admission decisions were likely based on the platelet count, which may have obscured the
276 association between other factors and disease severity.

277

278 DENV infections were confirmed using a combination of methods, though all but four cases
279 were positive by rRT-PCR (115/119, 96.6%). NS1 was detected in 71.4% of infections and
280 proved specific for DENV (96.4%). Notably, the performance of this commercial NS1 kit has
281 not been published, but results appeared similar to those reported for other rapid NS1 assays
282 (Blacksell et al. 2011). Consistent with previous observations, viral loads were significantly
283 higher among NS1-positive individuals (Duong et al. 2011; Duyen et al. 2011; Erra et al. 2013;
284 Tricou et al. 2011). Both viral load and NS1 detection were significantly associated with the
285 detection of anti-DENV IgG and anti-ZIKV IgG, which in this study was directed against the
286 NS1 antigen. In an earlier study, ZIKV-specific neutralizing antibodies were not detected among
287 a subset of our patients (A. Rojas, unpublished data). As such, anti-ZIKV IgG identified by
288 ELISA in the current study is favored to represent cross-reacting anti-DENV antibodies. In the
289 subset of patients with results for both IgG assays, the presence of anti-ZIKV NS1 IgG
290 accounted for virtually all false-negative NS1 results. Although such antibodies have been
291 known to reduce NS1 detection in secondary cases (Jayathilaka et al. 2018; Lee et al. 2015; Lima
292 Mda et al. 2014), the pathophysiologic significance of anti-NS1 antibodies in human DENV
293 infections remains unclear (Glasner et al. 2018; Jayathilaka et al. 2018). We demonstrate that
294 these antibodies can be detected in the acute-phase and, in combination with anti-DENV IgG, are
295 more common among hospitalized dengue cases. These serologic findings combined with an
296 elevated DENV viral load warrant further evaluation using standardized severity criteria (World
297 Health Organization 1997; World Health Organization 2009).

298

299 Dengue cases were less likely to report living in a house or apartment (recorded as “other” in the
300 study questionnaire). This was also observed in a seroprevalence study in Mexico where these

301 patients reported a “shared” living arrangement (Pavia-Ruz et al. 2018). Other aspects of the
302 home environment evaluated in our study did not differ between dengue and non-dengue cases.
303 The absence of air conditioning and window screens did not appear to increase the risk for
304 DENV infection. However, complete screening of the home and air conditioning have been
305 associated with decreased vector indices and dengue incidence in other settings (Manrique-Saide
306 et al. 2015; Pavia-Ruz et al. 2018; Reiter et al. 2003; Waterman et al. 1985), and the addition of
307 screens has been proposed as a means of DENV control through improvements to the built
308 environment (Lindsay et al. 2017; Vazquez-Prokopec et al. 2016). Our findings may indicate that
309 patients acquired DENV outside the home or that the use of these interventions is incomplete
310 (e.g. non-intact screens, intermittent use of air conditioning). Determining the location of
311 exposure will have important implications for DENV control efforts in metro Asunción.

312

313 Vaccination against YFV is not part of the routine schedule in Paraguay, and as a result, our
314 patient population included a mixture of individuals who did or did not report receiving the
315 vaccine. There was no evidence of increased risk from YFV vaccination for either incident
316 dengue or the development of severe disease. These data are consistent with recent findings from
317 Brazil where no association was found between severe dengue and receipt of the YFV vaccine
318 (Luppe et al. 2019).

319

320 DENV-1 was the predominant serotype identified in the current study. This is consistent with
321 recent DENV epidemiology in Paraguay, but it may limit the generalizability of our findings for
322 other serotypes. An additional limitation to the study is that we were unable to evaluate the
323 performance of the clinical case definition for different arboviral infections, and in particular

324 ZIKV infections that may not present with fever (Braga et al. 2017). Finally, patients were
325 included who reported up to 8 days of symptoms prior to enrollment. Laboratory data from day 8
326 produced conflicting results and raises questions regarding the accuracy of symptom recall past
327 one week. These data support the use of earlier enrollment cut-offs with scheduled follow-up
328 visits to monitor the kinetics of certain laboratory findings.

329

330 **Conclusions**

331 In this study, we sought to characterize DENV infections in a predominantly adult population in
332 Paraguay, focusing on the region with the highest dengue incidence, metro Asunción. This work
333 highlighted clinical, epidemiologic, and laboratory factors that are associated with DENV
334 detection in the acute setting and the potential role of specific antibodies in diagnosis and the
335 progression of disease. Future directions will involve the prospective evaluation of how factors
336 identified in the current study associate with and may predict dengue severity.

337 **Acknowledgements**

338 We thank the members of the study team based at the Instituto de Investigaciones en Ciencias de
339 la Salud, Universidad Nacional de Asunción, and Hospital Villa Elisa in Paraguay for their
340 dedication and excellent work, and we are grateful to the study participants and their families.
341 The authors would like to thank Diagnostic Bioprobes who kindly provided the ZIKVG.CE kits
342 used in this study as well as Muktha Natrajan and Varun Phadke for their thoughtful comments
343 during the preparation of this manuscript.

477 **Figure Legends**

478 **Figure 1.** Sensitivity of rRT-PCR, NS1, and IgM for dengue based on day of illness at
479 presentation.

480

481 **Figure 2.** DENV-1 viral load by day of illness at presentation (A). Viral loads are shown for
482 individual samples; bars display the mean and 95% CI. Six patients had infections with DENV-2
483 (n=3) or DENV-4 (n=3), which are not displayed. DENV viral load at presentation decreases in a
484 stepwise manner among individuals with anti-ZIKV IgG, anti-DENV IgG, or both (B). Results
485 were significant by ANOVA for both analyses, $p < 0.0001$.

486

487 **Figure 3.** Platelet (A) and leucocyte (B) counts at presentation among dengue cases (●) and non-
488 dengue cases (▲). Bars represent means \pm 95% CI; population mean values are shown. P values
489 (t test): **** = $p < 0.0001$.

Table 1 (on next page)

DENV diagnostic test results according to test method. DENV viral load is shown for rRT-PCR positive samples within a given category.

- 1 **Table 1.** DENV diagnostic test results according to test method. DENV viral load is shown for
- 2 rRT-PCR positive samples within a given category.

Test Results	Composite Definition		Day of Illness mean (sd)	Viral Load mean (sd) ^a
	Positive	Negative		
	(n = 119)	(n = 112)		
Combination of Methods				
rRT-PCR	28 (23.5)	—	3.1 (1.5)	6.10 (1.69)
rRT-PCR and NS1	60 (50.4)	—	3.2 (1.4)	7.85 (1.27)
rRT-PCR, NS1, and IgM	21 (17.7)	—	5.3 (1.3)	5.40 (1.19)
rRT-PCR and IgM	6 (5.0)	—	6.7 (1.0)	3.58 (0.22)
NS1 and IgM	4 (3.4)	—	7.2 (0.1)	—
Negative	—	112	3.2 (1.6)	—
Positives according to method				
rRT-PCR	115 (96.6)	—	3.7 (1.7)

Hemoglobin, g/dL, mean (sd)	13.9 (1.5)	14.0 (1.5)	13.8 (1.5)		
Platelet count, per μL , mean (sd)	217,550 (89,921)	188,227 (82,079)	252,609 (86,650)		<0.001
Thrombocytopenia, <150,000 per μL	46 (22.8)	36 (32.7)	10 (10.9)	4.0 (1.9-8.2)	<0.001
Leucocyte count, cells per mm^3 , mean (sd)	6090 (3686)	4158 (2023)	8401 (3899)		<0.001
Leucopenia, < 4,000 cells per mm^3	73 (36.1)	63 (57.3)	10 (10.9)	11.0 (5.1-22.2)	<0.001

2 Abbreviations: CI confidence interval; OR, odds ratio; sd, standard deviation

- 3 ^a Values presented as n (%) unless otherwise indicated, percentages were calculated based on the
4 number of patients with data recorded for a particular variable
5 ^b OR of having a dengue case versus a non-dengue case

Table 4(on next page)

Clinical history and test results among hospitalized and outpatient dengue cases at Hospital Villa Elisa.

1 **Table 4.** Clinical history and test results among hospitalized and outpatient dengue cases at
 2 Hospital Villa Elisa.

Patient Factors ^a	Total	Hospitalized	Outpatient	OR (95% CI) ^b	p-value
Patients	100 (100)	26 (100)	74 (100)		
<i>History and Clinical findings</i>					
Gender, female, n (%)	52 (52.0)	12 (46.2)	40 (54.1)		
Age, mean (sd)	31.6 (14.5)	36.5 (20.0)	29.9 (11.6)		0.044
Day of illness	3.81 (1.84)	5.0 (2.4)	3.4 (1.4)		<0.001
YFV vaccination	23/64 (35.9)	5/16 (31.2)	17/48 (35.4)		
Past dengue, per report	34/99 (34.3)	12/25 (48.0)	22/74 (28.6)	2.2 (0.9-5.5)	0.143
Rash	28/96 (29.2)	13/25 (52.0)	15/71 (21.1)	4.0 (1.5-10.0)	0.005
Diarrhea	27/100 (27.0)	11/26 (42.3)	16/74 (21.6)	2.7 (1.0-6.9)	0.070
Bleeding	18/100 (18.0)	10/26 (38.5)	8/74 (10.8)	5.2 (1.8-14.1)	0.006
<i>Dengue test results</i>					
rRT-PCR, positive	99 (99.0)	25 (96.2)	74 (100)		
Viral load, mean (sd)	6.44 (2.04)	6.76 (1.84)	5.51 (2.35)		0.028
NS1	69 (69.0)	17 (65.4)	52 (78.4)	0.8 (0.3-2.0)	0.632
IgM, anti-DENV	25 (25.0)	10 (38.5)	15 (20.3)	2.5 (1.0-6.6)	0.112
IgG, anti-DENV	28 (28.0)	14 (53.9)	14 (18.9)	5.0 (1.9-12.2)	0.002
IgG, anti-ZIKV	19/70 (27.1)	7/16 (43.8)	12/54 (22.2)	2.7 (0.9-8.1)	0.114
IgG against both DENV and ZIKV	13/67 (19.4)	7/13 (53.8)	6/54 (11.1)	9.3 (2.2 - 36.3)	0.002
<i>Laboratory results ^c</i>					
Hemoglobin, g/dL, mean (sd)	14.1 (1.4)	14.0 (2.0)	14.2 (1.2)		
Platelet count, per μ L, mean (sd)	191,563 (85,951)	119,250 (77,402)	215,667 (74,749)		<0.001
Thrombocytopenia, <150,000 per μ L	31 (32.3)	18 (75.0)	13 (18.1)	13.6 (4.5 - 43.2)	<0.001
Leucocyte count, cells per mm^3 , mean (sd)	4167 (2135)	4814 (3209)	3952 (1604)		0.087
Leucopenia, < 4,000 cells per mm^3	55 (57.3)	13 (54.2)	42 (58.3)		

3 Abbreviations: CI confidence interval; OR, odds ratio; sd, standard deviation

4 ^a Values presented as n (%) unless otherwise indicated

5 ^b OR for hospitalization versus outpatient care

6^c Lab results were available for 24 and 72 hospitalized cases and outpatients, respectively.

Figure 1 (on next page)

Sensitivity of rRT-PCR, NS1, and IgM for dengue based on day of illness at presentation.

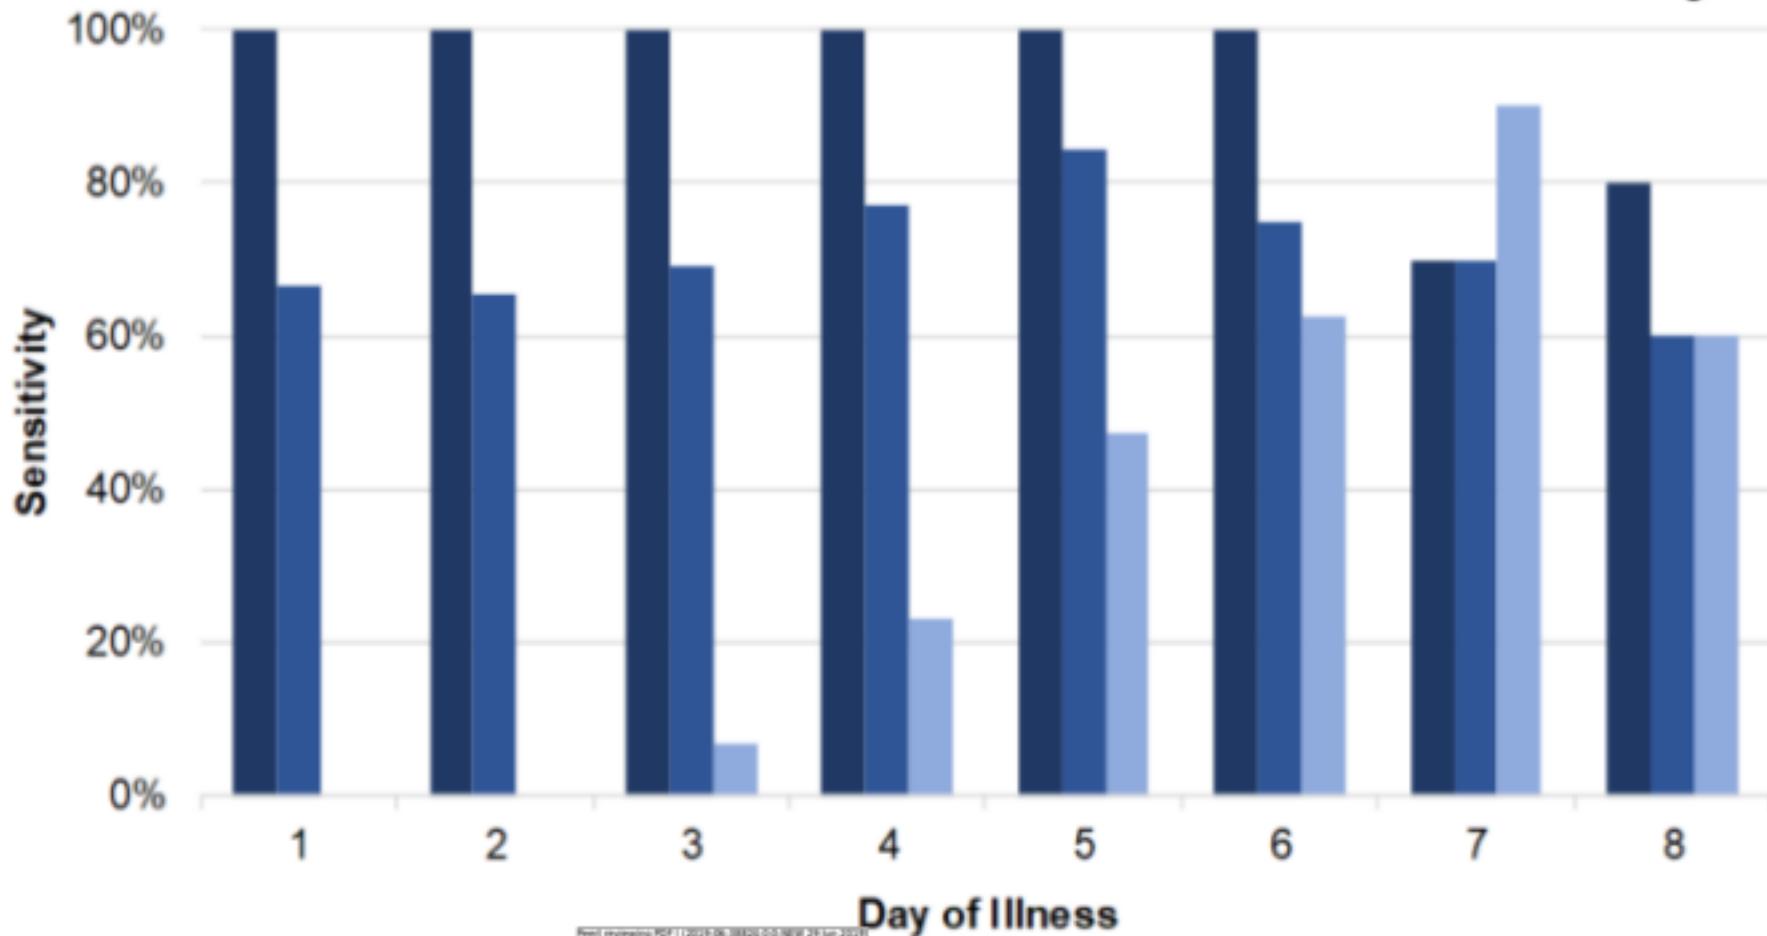

Figure 2(on next page)

DENV viral load at presentation based on day of illness and antibody status.

DENV-1 viral load by day of illness at presentation (A). Viral loads are shown for individual samples; bars display the mean and 95% CI. Six patients had infections with DENV-2 (n=3) or DENV-4 (n=3), which are not displayed. DENV viral load at presentation decreases in a stepwise manner among individuals with anti-ZIKV IgG, anti-DENV IgG, or both (B). Results were significant by ANOVA for both analyses, $p < 0.0001$.

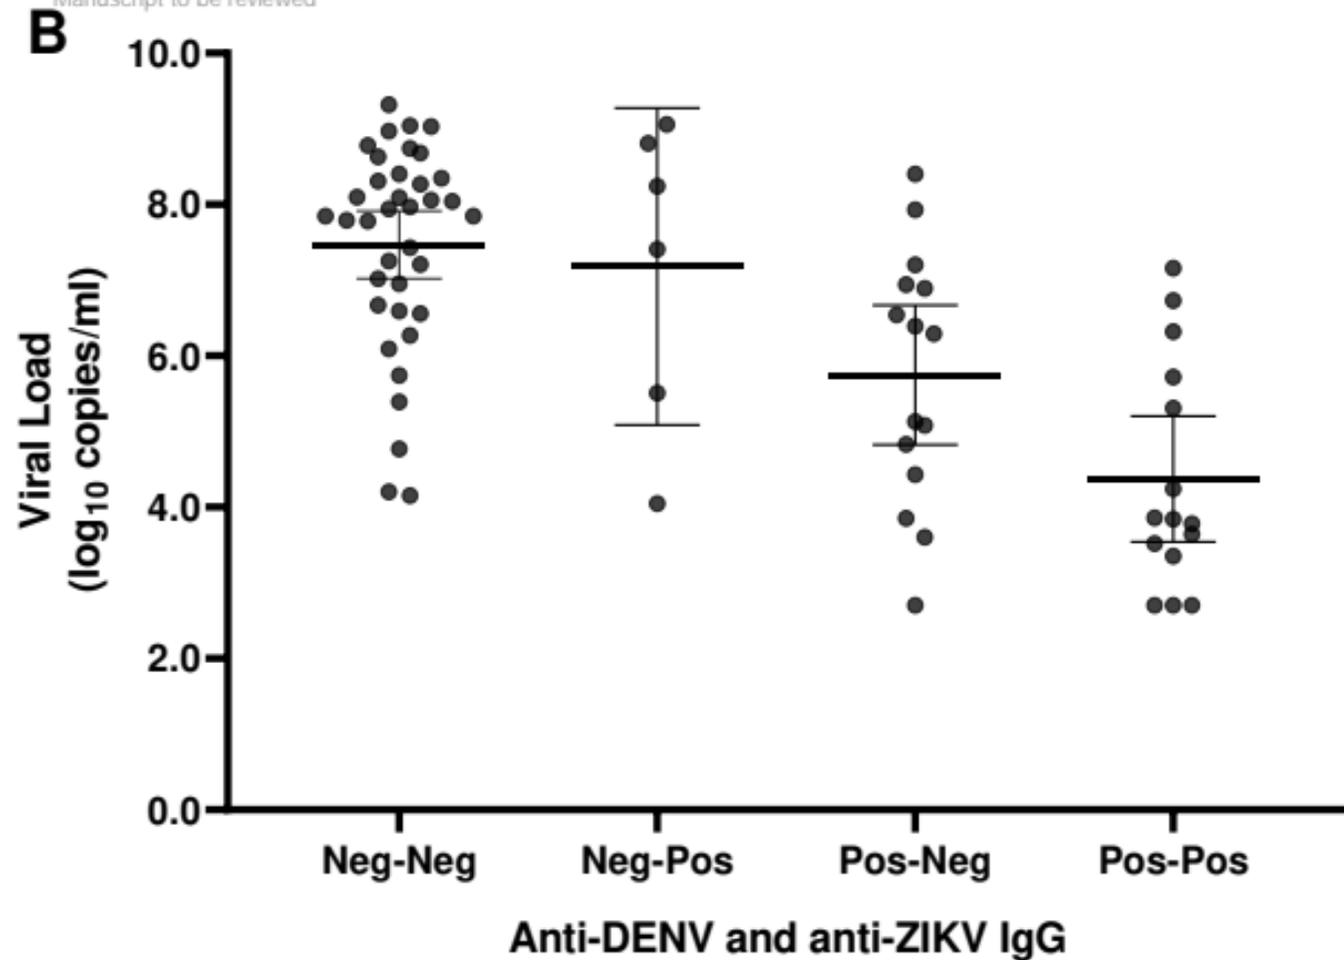

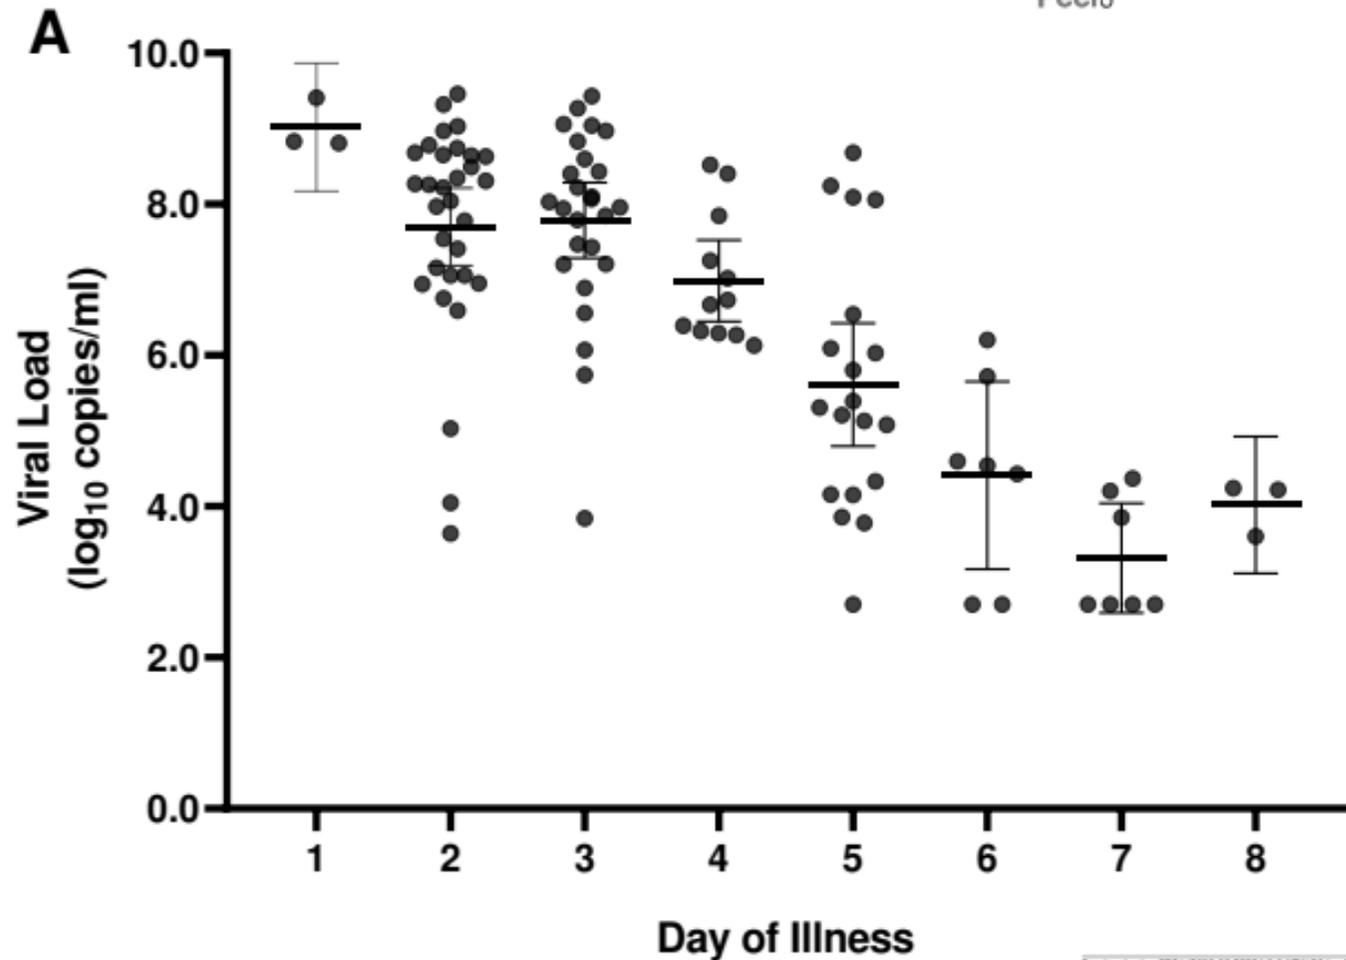

Figure 3(on next page)

Platelet (A) and leucocyte (B) counts at presentation among dengue cases (●) and non-dengue cases (▲).

Bars represent means \pm 95% CI; population mean values are shown. P values (t test): **** = $p < 0.0001$.
