Abstract

OBJECTIVES Assessing medical students' attitudes toward patient-centred care is essential to bettering medical education. Based on doctor-patient relationships and the medical system in China, it is important to explore the impact of gender differences and other background factors on patient-centred attitudes and to provide references for medical education reform.

METHODS A cross-sectional study was conducted on fourth-year medical undergraduate students from November 2017 to March 2018 in Heilongjiang Province, Northeast China. The Chinese-revised Patient-Practitioner Orientation Scale (CR-PPOS), which has been validated in previous research, was used to measure the medical students' attitudes .The medical students' demographic data was collected, including their gender, age, information on whether they have siblings, family residence location, doctor(s) for parents, year in which the student first experienced clinical practice, and student category.

RESULTS A total of 513 students (91.12%) completed the survey. The Chinese medical students scored considerably higher for 'Caring' (including patients' preferences into the decision-making process) than for 'Sharing' (sharing information/responsibility with patients). These students tended to have patient-centred attitudes, as measured by an average overall CR-PPOS score of 3.63 (scores higher than 3.5 indicate patient-centred attitudes), which is higher than Malian (3.38) and Pakistani (3.40) medical students but lower than American (4.57) and Brazilian (4.66) students. Female students ($P<0.05$) were significantly associated with more patient-centred attitudes and with higher 'Sharing' and 'Caring' subscale scores. Student category ($P<0.05$) was associated with 'Sharing' and 'Caring' scores. Clinical hospital students ($P<0.05$) were associated with more patient-centred attitudes and with higher 'Sharing' and 'Caring' subscale scores., Students without siblings ($p<0.07$) were associated with the higher 'Sharing' subscale scores.

CONCLUSIONS In China, gender has a significant impact on medical students' patient-centred attitudes, which is similar to findings from other countries. If medical schools want to raise patient-centred attitudes across the board and bridge the gap between male and female patient-centred attitudes, gender, student category, and other factors should be incorporated into medical education.

50 ABSTRACT

51 OBJECTIVES Assessing medical students' attitudes toward patient-centred care is essential to
52 bettering medical education. Based on doctor-patient relationships and the medical system in
53 China, it is important to explore the impact of gender differences and other background factors on
54 patient-centred attitudes and to provide references for medical education reform.

55 METHODS A cross-sectional study was conducted on fourth-year medical undergraduate students
56 from November 2017 to March 2018 in Heilongjiang Province, Northeast China. The Chinese-
57 revised Patient-Practitioner Orientation Scale (CR-PPOS), which has been validated in previous
58 research, was used to measure the medical students' attitudes .The medical students' demographic
59 data was collected, including their gender, age, information on whether they have siblings, family
60 residence location, doctor(s) for parents, year in which the student first experienced clinical
61 practice, and student category.

62 RESULTS A total of 513 students (91.12%) completed the survey. The Chinese medical students
63 scored considerably higher for 'Caring' (including patients' preferences into the decision-making
64 process) than for 'Sharing' (sharing information/responsibility with patients). These students
65 tended to have patient-centred attitudes, as measured by an average overall CR-PPOS score of
66 3.63 (scores higher than 3.5 indicate patient-centred attitudes), which is higher than Malian (3.38)
67 and Pakistani (3.40) medical students but lower than American (4.57) and Brazilian (4.66)
68 students. Female students ($P<0.05$) were significantly associated with more patient-centred
69 attitudes and with higher 'Sharing' and 'Caring' subscale scores. *Student category* ($P<0.05$) was
70 associated with 'Sharing' and 'Caring' scores. *Clinical hospital students* ($P<0.05$) were associated
71 with more patient-centred attitudes and with higher 'Sharing' and 'Caring' subscale scores.,
72 *Students without siblings* ($p<0.07$) were associated with the higher 'Sharing' subscale scores.

73 CONCLUSIONS In China, gender has a significant impact on medical students' patient-centred
74 attitudes, which is similar to findings from other countries. If medical schools want to raise patient-
75 centred attitudes across the board and bridge the gap between male and female patient-centred

76 attitudes, gender, student category, and other factors should be incorporated into medical

77 education.

78 Keywords: Patient-centred care, Medical education, Gendered differences

79 INTRODUCTION

80 Traditional biomedicine practices are based on Western science, focusing on the specific disease

81 rather than the patient as a whole and tending to grant doctors the decision-making power. (Engel,

82 1980) Patient-centred care, which was proposed by Balint et al. and is an overall approach to

83 medical practice compared with the biomedical medical practice, treats patients as unique human

84 beings and establishes a more egalitarian relationship between doctor and patient. (Balint, 1969;

85 Ishikawa et al., 2013) Byrne et al. and Levenstein et al. further expanded upon these ideas, which

86 have attracted the attention of medical practices over the past few decades. (Levenstein et al., 1986)

87 Patient-centred care has been recognized as an indispensable factor that is vital to improving the

88 quality of healthcare delivery, patient care strategies, and medical education. (Aljuaid et al., 2016)

89   Patient-centred care refers to the establishment of relationships among doctors, patients, and

90 their families in order to care for patients' needs and preferences and to provide the necessary

91 information and support so that patients can actively participate in clinical decision-making and in

92 their own care. (America, 2001; Health & Delivery, 2001) With this approach, doctors use their

93 communication skills to understand the patient's ideas, expectations, emotions, preferences, and

94 concerns about the illness in order to seek an integrated understanding of the patient's world.

95 (Stewart, 2001; Epstein et al., 2005; Stewart et al., 2000) Patient-centred care can also be described

96 with two dimensions. The first dimension (i.e. the sharing dimension) refers to the sharing of

97 power, responsibility, and information. The second dimension (i.e. the caring dimension) considers

98 whether the patient's feelings, expectations, and preferences are taken into account in medical

99 decision-making. (Lee et al., 2008a) Patient-centred care has been associated with positive patient

100 outcomes in many fields by increasing satisfaction, promoting effective communication, reducing

101 medical complaints, decreasing consultation time, improving perceptions on service delivery

102 quality. (Pereira et al., 2013; Stone, 2008; Hudon et al., 2011)

103   With an increase in the realization of patient-centred care's advantages and importance, this

104   approach has attracted attention worldwide and been measured in many countries including the

105   United States, Brazil, and Pakistan (Haidet et al., 2002; Ribeiro et al., 2007; Ahmad et al., 2015;

106   Mudiyanse et al., 2015). In recent years, medical educators have gradually established clinical

107   practice courses with the purpose of teaching communication skills, professional values, attitudes,

108   and humanistic behaviors to medical students. (Schmidt, 1998) In healthcare and medical

109   education, it is important to assess practitioners' attitudes about care. (Pereira et al., 2013) The

110   Patient-Practitioner Orientation Scale (PPOS) is an instrument that was developed in 1999 in

111   America to assess physicians', medical students', and patients' attitudes regarding whether

112   providers and patients should have equal power and control. (Krupat et al., 1999; Street et al.,

113   2003; Krupat et al., 2000) The Patient-Practitioner Orientation Scale (PPOS) contains a four-

114   element patient-centred care model and has been translated into different languages and validated

115   in several countries. (Krupat et al., 1999; Kim, 2013; Tsimtsiou et al., 2014; Dockens et al., 2016)

116   In southwest China, Ting et al. first attempted to use the PPOS to investigate patients' perceptions

117   of patient-centred communication in doctor-patient consultations. (Ting et al., 2016) Later, Wang

118   et al. improved the Chinese translation and incorporated characteristics of Chinese culture and the

119   Chinese medical and healthcare fields to develop the Chinese-revised Patient-Practitioner

120   Orientation Scale (CR-PPOS), which was based on the original PPOS scale. (Wang et al., 2017)

121   First, the patient-centred scale was sinicized with the permission of the original author to translate

122   it in a Chinese context. Next, the bilingual PPOS versions were separately sent to five advanced

123   health practitioners in China for further modifications. After that, the Chinese PPOS (C-PPOS)

124   was then retranslated into English and sent back to the original author for confirmation regarding

125   its accuracy. Finally, based on reliability, validity, and discriminative power tests, the C-PPOS

126   was revised to the CR-PPOS. The psychometrics of the CR-PPOS has been validated with a

127   reliability test (test-retest reliability) and validity tests (exploratory factor analysis, confirmatory

128   factor analysis, and internal consistency). In the relevant study, the results were within the

129   acceptable range. Wang et al. conducted a survey with the CR-PPOS in Shanghai, China to

130   investigate preferences towards patient-centred communication among physicians and patients.

131   This is the only known application of CR-PPOS in China. (Wang et al., 2017) Though it is an

132   innovative tool, the CR-PPOS does not measure medical students' patient-centred attitudes in

133   China. For example, it only explores physicians' and patients' views on patient-centred

134   communication and lacks medical students' views.

135   Medical students' patient-centred attitudes have been measured in numerous countries. For

136   instance, American scholar Krupat et al. measured first-year US medical students' patient-centred

137   attitudes and found that female students scored higher on patient-centred attitude scales than did

138   male students.(Krupat et al., 1999) Additional American scholars, Haidet and colleagues,

139   conducted studies on patient-centred attitudes during medical education programs and established

140   that there are gender differences in such attitudes; female medical students have a higher

141   prevalence of these attitudes (Haidet et al., 2002). Furthermore, Kheng Hock Lee, in his study on

142   Asian (Indian) students' patient-centred attitudes, also demonstrated the same gender differences

143   (Lee et al., 2008b). Therefore, existing studies have reported that there are gender differences in

144   patient-centred attitudes. The present study will advance measurements of Chinese medical

145   students' patient-centred attitudes, and it will explore whether gender and other background factors

146   impact such attitudes (as has been established in countries outside of China).   In doing so, the

147   present study will increase an understanding of patient-centred attitudes in China, and it will

148   provide references for future medical education practices based on China's current doctor-patient

149   relationships and its medical/healthcare policy background.

150

151   METHODS

152   **Study population**

153   A cross-sectional study was conducted from November 2017 to March 2018 in Heilongjiang

154   Province, Northeast China, which has a population of approximately 38.1 million people. The

155   participants were all fourth-year medical undergraduate students at Harbin Medical University's

156   First, Second, and Fourth Affiliated Hospitals. Harbin Medical University offers two types of the

157 length of schooling, a five-year category and a seven-year category. At this university, the first 3.5

158 years of study are considered to be 'pre-clinical' (with the occasional clinical practice courses),

159 and the last years (either 1.5 or 3.5 years, depending on the length of schooling) are entirely clinical

160 and provide students with opportunities to interact with patients. During the present study's

161 investigation, the fourth-year students were involved in multiple clinical rotations. The surveyor

162 distributed the questionnaire in person to the students during breaks between two classes. Also,

163 the surveyor informed the students of how to fill in the questionnaire and supervised the entire

164 process until the student completed the questionnaire in order to ensure quality and efficiency.

165 Participation in the survey was voluntary, and the researchers obtained oral informed consent prior

166 to beginning the study and a group-wide oral informed consent was read by the investigators to

167 the participants. Next, all participants completed a self-administered questionnaire within 10-15

168 minutes. The data were collected anonymously to ensure participants' confidentiality. Of the 563

169 distributed questionnaires, 513 were considered valid and the valid response rate was 91.12%.

170

171 **Study instrument**

172 The original PPOS includes 18 items, (Krupat et al., 1999) and each item is presented as a

173 statement in which respondents are asked to indicate their attitudes using a six-point Likert scale,

174 from *strongly agree* to *strongly disagree*.(Krupat et al., 2000; Street et al., 2003) The scale includes

175 the 'Sharing' and 'Caring' dimensions (as described previously). Given the particularities of

176 Chinese culture and the differences in doctor-patient relationships across countries, the present

177 study utilized a survey with the CR-PPOS scale. The CR-PPOS scale is a self-administered

178 questionnaire, and it contains 11 items and two subscales. (Wang et al., 2017) Of the 11 items, five

179 were used to evaluate caring attitudes and the remaining items were used to evaluate sharing

180 attitudes. The CR-PPOS item scores range from *strongly disagree* =1 to *strongly agree* =6. In

181 order to be comparable with foreign PPOS scores, the CR-PPOS score is inverted so that higher

182 scores indicate more patient-centred attitudes. The CR-PPOS average score is from 1 to 6, and

183   scores higher than 3.5 indicate patient-centred attitudes; the rest of the scores represent doctor-

184   centred attitudes.

185

186   **Data analysis**

187   Frequencies and percentages were calculated for the demographic characteristics (measured as

188   categorical variables). The demographic information collected in the survey included gender

189   (male/female), age (≤22/＞22), student category (Yang et al., 2014) (five-year or seven–year

190   category), without siblings (yes/no), family residence location (city, town, or village), whether the

191   student's parents are doctors (yes/no), and year in which the student first experienced clinical

192   practice (second year and below/ third year and above). We included the variable that measured

193   whether the one-child policy has an impact on the patient-centred attitude of medical students.

194   Likewise, we included students' residential backgrounds (e.g. village or town) because we expect

195   that students from socially closer communities which families are closely connected with each

196   other and have more neighborhood care and concern will be more likely to develop patient-centred

197   attitudes.

198   The CR-PPOS descriptive statistics for the different genders were analyzed by calculating the

199   means for the total scores. To do so, a T test was used to conduct a difference comparison. A single

200   factor analysis was conducted by comparing the differences in CR-PPOS scores (overall CR-

201   PPOS, 'Caring' subscale, and 'Sharing' subscale), and the scores were examined with T tests for

202   all of the categorical variables listed above (i.e., gender, age, residence, etc.).   A one-way analysis

203   of variance (ANOVA) was conducted for the students from clinical hospitals (the First, Second,

204   and Fourth-affiliated hospitals), with statistical significance set at $P < .05$. After one-way analysis,

205   statistically significant variables were screened out and included in a multi-factor regression model

206   for multivariable logistic regression analysis. The social demographic characteristics of gender,

207   clinical hospitals, student category, without siblings, and family residence were taken as

208   covariables. The overall CR-PPOS, "caring" subscale, and "sharing" subscale were divided

209   according to median scores (above the median score was the highest level, and the median and

210   below were the lowest). In this study, an overall CR-PPOS score > 40 was "patient-centred" and

211   ≤ 40 was "doctor-centred," a "caring" subscale score > 17 was "patient-centred" and ≤ 17 was

212   "doctor-centred," and a "sharing" subscale score > 23 was "patient-centred" and ≤ 23 was "doctor-

213   centred." The dependent variable in the multivariable logistic regression included the following: 1

214   "patient-centred attitudes" and 0 "otherwise." Odds ratios (ORs) along with 95% confidence

215   intervals were calculated as the measure of association between the outcomes and exposures. All

216   data were inputted manually and organized in Epidata 3.1. For the data analysis, IBM SPSS V.22.0

217   for Windows was used.

218   **Ethical approval:** Approval to conduct this study was granted by the Research Ethics Committee

219   of Harbin Medical University.

220

221

222   RESULTS

223   **Study sample demographic characteristics**

224   A total of 513 students were surveyed, with 394(76.8%)students in the five-year clinical

225   category and 119 students(23.2%) in the seven-year clinical category. A majority of the

226   participants were female (60.4%). The participants' ages ranged from 19 to 25, and the mean age

227   was 22. Nearly two-thirds of the participants did not have brothers (sisters). Also, 219 (42.7%)

228   students lived in a city. More than 90% of respondents' parents were not doctors. In addition, 455

229   (88.7%) participants first had experience with clinical practices in their third year of medical

230   school or earlier. Table 1 displays the distribution of students.

231

232   *Table 1 Demographic characteristics of the study sample (n=513)*

233

234   **PPOS scores for different major categories and gender**

235   The average total CR-PPOS score for the entire cohort was 3.63±0.54, ranging from 1.00 to 5.55.

236   The average 'Caring' score for the entire cohort was 4.53±0.82, and the average 'Sharing' score

237   was 2.88±0.67. Figure 1 depicts the distributions of overall CR-PPOS scores by gender. The cross-

238 sectional difference in the 'Caring' subscale scores, the 'Sharing' subscale scores, and the total

239 CR-PPOS scores differed between females and males. Female students had significantly higher

240 overall PPOS, 'Caring', and 'Sharing' scores (3.69±0.60, 4.61±0.74, 2.92±0.63, respectively) than

241 did male students (3.54±0.50, 4.42±0.92, 2.81±0.72, respectively). Gender was significantly

242 associated with total CR-PPOS score, 'Caring' subscale score, and 'Sharing' subscale score

243 (*P*=0.002, *P*=0.009, *P*=0.051, respectively).

244

245 ***Figure 1*** *Distribution of 'Caring' subscale, 'Sharing' subscale, and CR-PPOS scores by gender*

246

247 **Single factor analysis for overall PPOS, 'Sharing' subscale, and 'Caring' subscale scores**

248 Three demographic variables were significantly related to higher overall CR-PPOS scores. Female

249 students, students who studied at the First-affiliated hospital, and students with no siblings all

250 demonstrated significantly higher patient-centred scores than students who were male and students

251 with siblings (*P*<0.05 for each comparison). There was a slight trend toward higher (i.e., more

252 patient-centred) scores among students who lived in villages but this was not statistically

253 significant (*P*=0.071).

254 The analysis of the 'Caring' subscale scores revealed additional associations with the

255 demographic variables. Higher 'Caring' scores indicate that doctors take patients' feelings,

256 expectations, and preferences into account in their decision-making process more than doctors

257 with lower 'Caring' scores. Female students, students who studied at the First-affiliated hospital,

258 and students in the seven-year clinical category had higher scores than other students *(P*<0.05).

259 There was a slight trend towards higher 'Caring' subscale scores for students who lived in villages,

260 but this trend was not statistically significant (*P*=0.086).

261 Three demographic variables were significantly associated with the 'Sharing' subscale

262 scores. Higher 'Sharing' scores indicate a greater belief that doctors share equal power, control,

263 and information with patients. Students older than 22-years-old, students in the five-year clinical

264 category, and female students had higher scores (*P* < 0.05, p <0.05, and p=0.051, respectively).

265   There was a slight trend toward higher (i.e., more patient-centred) scores for students who studied

266   at the First-affiliated hospital, but this was not statistically significant (P=0.061). The year in which

267   students first experienced clinical practice, as well as the students who have parents that are

268   doctors, had no bearing on patient-centred care attitudes. Table 2 displays these results.

269

270   *Table 2 Total and subscale PPOS scores by student demographic information**

271

272   **Multivariable Logistic regression analysis for overall PPOS, 'Sharing' subscale, and**

273   **'Caring' subscale scores**

274   Multivariable logistic regressions were used to analyze the factors that influence the students'

275   patient-centred attitude. In Caring Subscale ,those who were at seven-year clinical category and

276   those who studied in first affiliated hospital had higher patient-centred

277   attitude(OR=1.817,95%CI:1.187 ～ 2.782,OR=1.817,95%CI:1.455 ～ 3.009).There was a slight

278   trend toward female students.(OR=1.415,95%CI:0.976 ～ 2.053).In Sharing Subscale, female

279   students, students who were at five-year clinical category and those who studied in first affiliated

280   hospital had higher patient-centred attitude(OR=1.470, 95%CI:1.019~2.119; OR=0.483,

281   95%CI:0.313 ～ 0.746; OR=1.740, 95%CI:1.210 ～ 2.503). There was a slight trend toward students

282   who didn't have siblings (OR=1.463, 95%CI:0.984 ～ 2.175). In total CR-PPOS, students who

283   studied in first affiliated hospital had higher patient-centred attitude (OR=2.286, 95%CI:1.591 ～

284   3.284).There was a slight trend toward female students who didn't have siblings (OR=1.438,

285   95%CI:0.994 ～ 2.079).Table 3 displays these results.

286   *Table 3 Variables influencing total and subscale PPOS scores*

287   *P < 0.05, [#]P<0.07

288   DISCUSSION

289   This is the first study to report on Chinese medical students' attitudes toward patient-centred care.

290   Comparing the Chinese medical students' scores with non-Chinese medical students' scores

291   (measured with the same tool) promotes a more comprehensive understanding of Chinese medical

292   students' patient-centred attitudes. This study's results are consistent with the results obtained in

293   most other countries, indicating that female students tend to be more patient-centred than male

294   students. (Haidet et al., 2002; Ribeiro et al., 2007; Lee et al., 2008b)

295   In general, Chinese medical students tended toward patient-centred attitudes, as indicated by

296   a mean CR-PPOS score of 3.63 (scores higher than 3.5 indicate patient-centred attitudes), which

297   is higher than Malian (3.38) and Pakistani (3.40) medical students but lower than American (4.57)

298   and Brazilian (4.66) medical students. (Hurley et al., 2018; Ribeiro et al., 2007; Haidet et al., 2002;

299   Ahmad et al., 2015) The Chinese medical students' 'Sharing' subscales (2.88) were generally

300   lower than Malian (3.04), Pakistani (3.18), and Brazilian (4.10) medical student scores. However,

301   the Chinese medical students' 'Caring' subscales (4.53) were generally lower than Brazilian

302   students (5.20) but higher than Pakistani (3.63) and Malian (3.68) students. Therefore, the Chinese

303   scores were lower than the scores reported by studies conducted in America and Brazil, but the

304   Chinese scores are nearly equivalent to scores obtained in Pakistan and Mali.

305   These results might be explained by differences in socio-economic conditions or by religious

306   and cultural differences across countries. In China, the results indicate that, although medical

307   students generally have mid-level patient-centred attitudes, they have higher preferences for

308   'Caring' than for sharing information with patients and engaging in decision-making with patients.

309   The difference in "Caring" versus "Sharing" subscales might be explained by different cultural

310   values, because in Asian cultures, patients prefer doctors who are more likely to make "family-

311   based" or "doctor-based" decisions in the process of diagnosis and treatment. This differs from the

312   culture in Western countries, where patients prefer that the doctors share veracious 'breaking bad

313   news', such as managing end-of-life care. It is a similar to Africa's cultures that have similarly

314   seen higher caring scores as compared to sharing.(Lee et al., 2008b; Searight & Gafford, 2005; Tai

315   & Tsai, 2003; Hurley et al., 2018) In China, Ting et al. found that patients were more likely to rely

316   on doctors to control consultations, decision-making, and information distribution; also, Ting et

317   al. established that patients do not think that they have the knowledge or ability to handle medical

318   issues. (Ting et al., 2016; Epstein et al., 2005) The higher 'Caring' subscales might be due to

319   medical students hoping that doctor-patient relationships can be based on mutual understanding

320 and that patients can be treated in a friendly way in accordance with their psychosocial background

321 information.(Ting et al., 2016)

322   This study showed that there is a difference between female and male students in that female

323 students tend to have more patient-centred attitudes than male students. (Ribeiro et al., 2007) The

324 female students surveyed in this study displayed higher mean scores than male students for the

325 overall CR-PPOS scores and for the 'Sharing' and 'Caring' subscale scores. Women are seen as

326 more empathetic and as having better communitarian orientations than men. (Wahlqvist et al.,

327 2010) Hojat et al., in a study on the empathy of medical students, demonstrated that there are

328 differences by gender regarding the development of empathy throughout medical school. (Hojat

329 et al., 2009) Moreover, in communicating with patients, women (more so than men) have greater

330 communication abilities that involve more positive conversations, higher use of emotional

331 conversations, and active consultations with patients, which might mean that they are more

332 acceptable to patients. (Roter et al., 2002) Furthermore, these characteristics of female doctors

333 might explain why there are fewer lawsuits against female doctors around the world. (Sandhu et

334 al., 2009) In general, our results corroborate the findings of these existing studies.

335   Previous PPOS measurement results have indicated that patient-centred attitudes can be

336 influenced by both investigators' personal characteristics and social environmental factors. In the

337 present study, students at the First-affiliated hospital displayed higher CR-PPOS, 'Caring', and

338 'Sharing' mean scores for patient-centred care. It is plausible that these results can be explained

339 by patients' varying residences and by the specific economic conditions at the different affiliated

340 hospitals. Compared with other affiliated hospitals, the First-affiliated hospital patients were

341 largely from local areas, and they therefore harmoniously communicated with doctors due to

342 having similar cultural backgrounds. There is also evidence that patients' attitudes and behaviors

343 exhibited during the clinical encounters can influence doctors' patient-centred preferences, (Lee et

344 al., 2008b) which might help explain why the patient-centred care scores at the First-affiliated

345 hospital were higher than the scores obtained at the other hospitals.

346   The seven-year clinical category students had higher 'Caring' subscale scores than did the

347 five-year clinical category students; however, interestingly, they scored lower on the 'Sharing'

348 subscale than did the five-year category students. This might be because the seven-year category

349 medical students were participating in clinical doctor-patient communication courses during the

350 investigation; however, the five-year clinical category students had previously taken such courses

351 before the investigation started. The timing of when a student participates in the practical courses

352 has an impact on the 'Sharing' and 'Caring' dimensions. While taking a doctor-patient

353 communication course in clinical practice, the seven-year clinical category students are more likely

354 to have empathy and to be able to use the patients' perspectives to understand patients and to

355 provide care. Also, these students regard patients as a group that needs to be cared for rather than

356 as a group with equal rights to doctors; therefore, these students then have higher 'Caring' subscale

357 scores but lower 'Sharing' subscale scores compared with the five-year clinical category students.

358   This study also found that students with siblings have higher Sharing scores. One possible

359 explanation for this findings is that the students with siblings are more likely to share, to

360 communicate, and to pay attention to others' feelings in their daily lives. These explanations help

361 shed light on why these students achieved higher Sharing scores.

362

363 CONCLUSION

364 In general, our findings indicated that Chinese medical students' attitudes are more patient-centred

365 as measured by the CR-PPOS and 'Caring' subscale scores but less patient-centred as measured

366 by the 'Sharing' subscale scores. Gender has a significant impact on medical students' patient-

367 centred attitudes, as has been reported in other countries. Higher patient-centred attitudes were

368 also associated with seven-year clinical category students, students who studied at the First-

369 affiliated hospital, students from villages, and students without siblings.

370   Our research indicates that, if medical schools want to bridge the gap between male and

371 female patient-centred attitudes and to improve patient-centred attitudes, more attention should be

372 paid to the doctor-patient communication courses in clinical practice. The patient-centred

373 differences by gender, major categories, and other factors should be incorporated into medical

374 education. We suggest that the Chinese medical schools learn from Sweden's mixed-group

375 education method, in which male students actively role play doctor-patient communication

376 scenarios so that they develop patience and become approachable (even though there are still

377 distinct differences between men and women). (Wahlqvist et al., 2010) Moreover, it is important

378 that medical schools think critically about at which point in the categories they should offer the

379 relevant doctor-patient communication courses. In addition, this study also identifies that medical

380 students' personal characteristics and social environmental factors impact their patient-centred

381 care attitudes. Improving medical students' patient-centred skills via relevant medical education

382 can result in establishing more high-quality medical services in China. However, education reform

383 alone cannot fully achieve patient-centred care; instead, society as a whole and the entire

384 healthcare system also need to affirm the value and significant of patient-centred care before it can

385 be fully realized.

386

387 ***Limitations and suggestions for future research***

388 When interpreting our findings, we should bear in mind the limitations of our research. Through

389 further research in the future, we will more comprehensively explore the patient-centred attitude

390 of medical students.

391 1. The duration of the cross-sectional survey may have an impact on the patient-centred attitudes

392 of medical students.

393 2. As there are fewer CR-PPOS items than PPOS items, there may be some deviation in

394 comparing the patient-centred attitudes of medical students.

395 3. The analysis only included cross-sectional comparisons that focused on clinical medical

396 students in one city. It would be helpful if future research incorporated longitudinal analyses or

397 follow-up studies on other types of medical students (e.g., dental students).

398 4. Future related research might also include large sample sizes to increase our understanding of

399 this topic.

400 ***Acknowledgements:*** The authors would like to thank all medical students who responded to the

401 questionnaire.
