

Knowledge of malaria prevention among pregnant women and female caregivers of under-five children in rural southwest Nigeria

Ayodeji M. Adebayo, Oluwaseun O. Akinyemi, Eniola O. Cadmus

Introduction: The morbidity and mortality from malaria is still unacceptably high in the developing countries, especially among the vulnerable groups like pregnant women and under-five children, despite all control efforts. The knowledge about the preventive measures of malaria is an important preceding factor for the acceptance and use of malaria preventive measures like Insecticide Treated Nets (ITN) by community members. Therefore, this study assessed the knowledge of malaria prevention among caregivers of under-five children and pregnant women in a rural community in Southwest Nigeria.

Methodology: This is part of a larger malaria prevention study in rural Southwest Nigeria. A descriptive cross-sectional survey was conducted among pregnant women and caregivers of under-five children in Igbo-Ora, a rural town in Southwest Nigeria using a semi-structured, interviewer-administered questionnaire. Information was obtained on knowledge of malaria prevention and overall composite scores were computed for knowledge of malaria prevention and ITN use. Data were analyzed using SPSS version 16. Associations between variables were tested using Chi-square with the level of statistical significance set at 5%. **Results:** Of the 631 respondents, 84.9% were caregivers of under-five children and 67.7% were married. Mean age was 27.7 ± 6.3 years with 53.4% aged between 20 and 29 years. Majority (91.1%) had at least primary school education and 60.2% were traders. Overall, 57.7% had poor knowledge of malaria prevention. A good proportion (83.5%) were aware of the use of ITN for malaria prevention while 30.6% had poor knowledge of its use. Respondents who were younger (<30 years), had at least primary education and earn <10,000/ per month had significantly poor knowledge of ITN use in malaria prevention. Majority (60.0%) respondents had poor attitude regarding use of ITNs. **Conclusion:** This study showed that the knowledge of malaria prevention is still low among under-five caregivers and pregnant women in rural Southwest Nigeria despite current control measures. There is need for concerted health education intervention to improve the knowledge of rural dwellers regarding malaria prevention including the use of ITN. This will go a long way to improve the reported low level of ownership and utilization of ITN in the rural areas.

Knowledge of Malaria Prevention among Pregnant Women and Female Caregivers of Under-Five Children in Rural Southwest Nigeria

26 Introduction

27 Malaria is a completely preventable disease; however, about 3.4 billion people are at risk of the disease
 28 globally with 1.2 billion people at high risk (World Health Organization 2013). In 2012, malaria was
 29 responsible for the death of approximately 482,000 under-five children even though an estimated 136
 30 million Insecticide Treated Nets (ITNs) were distributed to endemic countries the same year (World
 31 Health Organization 2013). Thus, malaria is still a major public health concern particularly in sub-
 32 Saharan Africa and other parts of the developing world (Pluess et al. 2009; Pluess et al. 2010). In Nigeria,
 33 malaria is responsible for around 60% of the out-patient visits to health facilities, 30% of childhood
 34 death, 25% of death in children under one year and 11% of maternal deaths (National Population
 35 Commission 2008; Noland et al. 2014). Similarly, about 70% of pregnant women suffer from malaria;
 36 contributing to maternal anemia, low birth weight, still births, abortions and other pregnancy-related
 37 complications (Federal Ministry of Health Abuja 2005). The financial loss due to malaria is estimated to
 38 be about 132 billion Naira (\$797 million) annually in form of treatment costs, prevention costs, loss of
 39 man-hours (Noland et al. 2014; World Health Organization 2012).

40 Malaria, a debilitating febrile and life threatening illness, is caused by a parasite called Plasmodium. Its
 41 route of transmission still remains bites from infected female anopheles mosquitoes. Environmental
 42 factors and behavioral patterns of vectors and human populations combine to provide favorable
 43 conditions for malaria transmission (Boutin et al. 2005). Proven effective options to reduce morbidity
 44 and mortality include early diagnosis, combined with prompt effective therapy and malaria prevention
 45 through reduction of human-vector contact, especially with the use of ITNs (World Health Organization
 46 2007). Perceptions about malaria illness, particularly households' perceived susceptibility and beliefs
 47 about the seriousness of the disease are important preceding factors for decision-making concerning
 48 preventive and curative actions (Rakhshani et al. 2003). The understanding of the possible causes, modes
 49 of transmission, and individuals' preference and decision about adoption of preventive and control
 50 measures vary from community to community and among individual households (Adongo et al. 2005).
 51 There have been a considerable number of reports about knowledge, attitudes, and practices relating to
 52 malaria and its control from different parts of Africa. These reports concluded that misconceptions
 53 concerning malaria still exist and that practices for the control of malaria have been unsatisfactory
 54 (Ahorlu et al. 1997; Alaii et al. 2003; Laver et al. 2001; Obol et al. 2011).

55 Achieving sustainable control of the disease depend on extensive public health promotional programs
 56 which focus on current and proven methods of malaria prevention and management. While much is

known about vector biology and behaviour and the malaria parasites, the importance of human behaviour in malaria transmission has not been critically evaluated. Studies focusing on the current practices of malaria prevention and treatment options in the population are sparse. Thus, it is expedient to evaluate current knowledge of malaria prevention practices and management options as well as the uptake of the management options. In most high-burden countries (including Nigeria), ITN coverage is still below agreed targets (Minja & Obrist 2005). This may be related to the perception of its use among the community members. The knowledge about the preventive measures of malaria is an important preceding factor for the acceptance and use of ITN for malaria control by the community members (Minja et al. 2001). Therefore, this study assessed the knowledge of malaria prevention with emphasis on knowledge of ITN use among pregnant women and caregivers of under-five children in Igbo-Ora.

Igbo-Ora is a rural community in Ibarapa Central Local Government Area (LGA) of Oyo State, Southwest Nigeria. The main towns in the LGA are Igboora and Idere. Igboora is the larger town with a population of 60,000 people. The LGA has ten political wards with seven located in Igboora, the study site. Igbo-Ora is located about 128km from Lagos - the Nigerian economic capital. The predominant language in the study area is Yoruba. However, migrant farm labourers from the republic of Benin, Togo and Ghana reside in the LGA. There are some nomadic Fulanis who live in settlements around the town.

Igbo-Ora is further divided into six census areas comprised of 62 enumeration areas, each with an average population of 600 people. Furthermore, each enumeration area is divided into compounds and each compound has about 100 women in the reproductive age group.

77 **Methodology**

78 The study population is made up of pregnant women in their reproductive age (15-49 years) and female
79 caregivers of under-five children, who have lived in the community for at least one year. For the purpose
80 of this study, caregivers may include mothers and female guardians of under-five children.

81 A community-based descriptive cross-sectional survey was carried out using a multistage cluster
82 sampling technique. Three enumeration areas were selected by simple random sampling through
83 balloting from each of the six census areas. Subsequently, two compounds were selected from each of
84 these enumeration areas by balloting. A minimum sample size of 126 was estimated using Leslie and
85 Kish formula for approximating sample size for cross sectional study. This was multiplied by a factor of
86 two to adjust for clustering effect. A total of 631 eligible and consenting caregivers of under-five children
87 and pregnant women in the households within the selected compounds were then interviewed. All the
88 people who were approached consented to participate in the study.

89 A pre-tested semi-structured interviewer-administered questionnaire was used to collect information on
90 the socio-demographic characteristics of respondents, knowledge of malaria prevention and knowledge
91 of ITN use; and perception of ITN use in malaria prevention. Knowledge about malaria prevention and
92 ITN use were assessed through a six-point score each. A point was given to each correct answer 0 to
93 wrong answer. The mean knowledge score was used to dichotomize knowledge scores. Knowledge about
94 malaria prevention was categorized into “good” (4-6) and “poor” (0-3) while scores of 0-4 were deemed
95 poor and 5-6 were considered good for knowledge of ITN use for malaria prevention. The questionnaire
96 was translated to Yoruba in order to enable proper understanding by respondents and back-translated to
97 English to ensure that the original meaning was retained. Questionnaire administration was done by four
98 trained research assistants whose minimum educational qualification was National Certificate in
99 Education (NCE) or Ordinary National Diploma (OND) and were fluent in speaking the local dialect.
100 The questionnaire was pre-tested in Idere, the second main town in Ibarapa Central LGA.

101 Data were analyzed using the Statistical Package for Social Sciences (SPSS version 16). Associations
102 between variables were tested using Chi-square with the level of statistical significance set at 5%. The
103 raw data for this study may be accessed through:

104 <https://docs.google.com/a/cartafrica.org/file/d/0B62N6G90gxJZNzdIT05NQ2w1QWw/edit> .

The Oyo State Ethical Review Committee, Ministry of Health, Ibadan gave ethical clearance and approval for this study (reference number: AD 13/479/76). Informed verbal consent was also gotten from individual research participant before data collection. The respondents were also reminded of their right to decline to take part in the study as well as to withdraw any time during the interview. Confidentiality was assured and maintained throughout the study. The importance of the study was explained to participants as well as how their participation in the study will contribute towards malaria prevention programing in Nigeria.

Results

Figure 1 shows the distribution of respondents. A total of 631 respondents were interviewed, out of whom 536 (84.9%) were caregivers of under-five children. The socio-demographic characteristics of respondents are shown in Table 1. The mean age of respondents was 27.7 ± 6.3 years with about 53% aged between 20 and 29 years. More than 90% have at least primary education while trading (60.2%) was the most common occupation among respondents. About 70% were married and living with their spouses. A greater proportion, (71.9%) of respondents were either in or from a monogamous relationship. About 60% of respondents have 2 children or less while almost all (97.5%) have 2 or less under-five children. About 97% were from the Yoruba ethnic affiliation and more than half, (57.6%) were Muslims. Most respondents, 64.7% earned less than ₦10, 000 (\$59.4) monthly. Only 8.4% earned ₦30,000 (\$178.2) and above. The median average income was ₦5000 (\$29.7); range: ₦1000 – ₦150,000.

Table 2 revealed that less than half of respondents (42.3%) had good knowledge of malaria prevention. Table 3 shows respondents' knowledge regarding methods of malaria prevention. About 85%, 82%, and 75% knew that malaria could be prevented through keeping the environment clean, clearing of bushes around houses and use of ITN respectively. However, approximately 77% and 82% of respondents felt taking native concoction and using malaria prophylaxis respectively could prevent occurrence of malaria infection.

Nearly 84% of participants had heard of ITN while almost 70% had good knowledge of the use of ITN in malaria prevention (Table 4). Regarding the use of ITN in malaria prevention, about 80% knew that ITN is useful in malaria prevention and over three-quarters understood that it could kill mosquito (Table 5).

Table 6 shows attitude of under-five caregivers and pregnant women regarding ITN and its use. Roughly 63% of respondents did not agree that window/door nets was better or the same as ITN. Similarly, 61%

of participants disagreed with the statement that “ITN does not make any difference in malaria prevention”. Well over half of participants (56.1%) agreed that “either one uses mosquito net or not, those that will be infected with malaria will definitely have it”. Majority were indifferent as to whether ITN causing irritation, heat rash, cough, vomiting in pregnancy, miscarriage, mortality in children and bad odor.

Table 7 demonstrated that mothers and under-five caregivers with higher educational status, who were civil servants, with higher income, and married had good knowledge of malaria prevention ($p < 0.05$). Similarly respondents who earned high income and were married had significantly better knowledge of ITN use (Table 8).

Discussion

This study was conducted to assess knowledge of malaria prevention with emphasis on ITN use among female caregivers of under-five children and pregnant women in Igbo-Ora, a rural community in Southwest Nigeria. The overall knowledge of malaria prevention practices among majority of the respondents was found to be poor. This finding agrees with the submissions of Fawole and Onyiaso (2008) who showed that even among health workers in Ibadan, Southwest Nigeria, knowledge of malaria preventive strategies was poor. However, this finding is at variance with the conclusions of Adegun et al (2011) and Oyewole & Ibidapo (2007) who showed that the general knowledge about malaria prevention among urban residents in Southwest Nigeria was good. The knowledge picture seen among respondents in this study could be as a result of lack of exposure to health education messages regarding malaria prevention, being rural dwellers, or respondents’ poor health seeking behavior. For those who had exposure to health messages in health facilities, some might find it difficult to understand malaria prevention information given during antenatal and postnatal clinics. This might be due partly to inappropriate means of communication and delivery of these messages by the health workers in addition to the respondents’ low level of education. Respondents’ level of education was found to be significantly associated with knowledge of malaria prevention. Therefore, achieving malaria prevention, just like any other health message, depend on the level of education of respondents among other reasons.

Furthermore, relatively high proportions of the respondents in our study knew that use of antimalarial prophylaxis in pregnancy, clearing of bushes around the house and keeping the environment clean were part of malaria prevention strategies. The knowledge of the importance of prophylaxis for malaria

165 prevention may be a function of the fact that they had benefited from intermittent preventive treatment
166 (IPT) during index or previous pregnancies during which they might have had health education on the
167 issue. However, other studies from Nigeria (Falade et al. 2006; Okeke et al. 2006) and Tanzania (Comoro
168 et al. 2003) have documented that gaps still exist in the knowledge of causation and treatment of malaria
169 in rural areas and that these gaps have serious public health implications.

170 Most of these rural respondents still exhibited some myths and misconceptions about malaria prevention.
171 Drinking of native concoction and use of antibiotics for malaria treatment were some of the erroneous
172 believes reported. The finding on the use native concoction by pregnant women in Nigeria is
173 corroborated by Fakeye and colleagues (2009) who advised that questions on herbal drug use should be
174 routinely asked by health workers during antenatal care to forestall dangerous drug interactions. Herbal
175 preparations, though not medically recommended for the treatment of diseases like malaria is an innate
176 traditional practice which is considered normal by people because of a deep cultural attachment.
177 Inadequate information from health workers and respondents' low level of education could also
178 contribute to the misconceptions of malaria treatment. Continuous efforts at providing necessary
179 information by relevant health organizations are needed to control and prevent incidence of malaria in
180 the general public.

181 More than two-thirds of the respondents had good knowledge of ITN use for malaria prevention. Awosan
182 et al (2013), in a study to determine the prevalence and barriers to the use of insecticide treated nets among
183 pregnant women attending ante-natal clinic in a Specialist Hospital at Sokoto, reported similar finding.
184 However, in a hospital-based study about awareness of ITN use in Abeokuta, Southwest Nigeria,
185 Runsewe-Abiodun et al (2012) reported low awareness and linked this to the low utilization among the
186 pregnant women interviewed. The current ongoing aggressive public health campaign which involves
187 mass distribution of ITNs at PHC centers could account for the high awareness noted in this study.
188 However, some respondents had poor attitudes and misconceptions about the use of ITNs. Respondents'
189 attitudes may have a strong implication on ownership and utilization of ITNs (Onwujekwe et al. 2005).

190 **Conclusion and recommendations**

191 Despite concerted efforts at malaria control nationwide, knowledge of malaria prevention was below
192 average among rural caregivers of under-five children and pregnant women in the study area. Myths and
193 misconceptions about malaria prevention is still prevalent. There is a need for a concerted health
194 education intervention to improve the knowledge of rural dwellers regarding malaria prevention

195 especially with the use of Insecticide Treated Net. Continuous efforts at providing necessary information
 196 by relevant health organizations are needed to control and reduce incidence of malaria in the general
 197 public.

Table 7 (on next page)

Association between respondent characteristics and knowledge of malaria prevention

2 **Table 7: Association between respondent characteristics and knowledge of malaria prevention**

Variables	Knowledge of Malaria Prevention		Chi square	p-value
	Poor n(%)	Good n(%)		
Level of education				
No formal education	33 (58.9)	23 (41.1)	23.145	<0.001
Primary	131 (63.6)	75 (36.4)		
Secondary	165 (60.0)	110 (40.0)		
Tertiary	33 (35.1)	61 (64.9)		
Occupation				
Trading	232 (61.1)	148 (38.9)	35.317	<0.001
Artisan	34 (50.7)	33 (49.3)		
Civil servant	24 (30.8)	54 (69.2)		
Farming	14 (93.3)	1 (6.7)		
Others	58 (63.7)	33 (36.3)		
Average monthly income				
<10000	249 (61.0)	159 (39.0)	10.813	0.013
10000-19999	60 (56.1)	47 (43.9)		
20000-29999	25 (39.7)	38 (60.3)		
>=30000	28 (52.8)	25 (47.2)		
Marital Status				
Never married	86 (74.8)	29 (25.2)	17.436	<0.001
Ever married	276 (53.5)	240 (46.5)		
Religion				
Christianity	142 (53.0)	126 (47.0)	3.661	0.056
Islam	220 (60.6)	143 (39.4)		
Respondents				
Pregnant	42 (64.6)	23 (35.4)	5.128	0.077
Under-5-caregiver	310 (57.8)	226 (42.2)		
Both	12 (40.0)	18 (60.0)
