

Patient exposure in the basic science classroom enhances differential diagnosis formation and clinical decision-making

Justin G. Peacock, Joseph P. Grande

Purpose: The authors proposed that introducing real patients into a pathology classroom early in medical education would help integrate fundamental principles and disease pathology with clinical presentation and medical history.

Methods: Three patients with different pathologies described their history and presentation without revealing their diagnosis. Students were required to submit a differential diagnosis in writing, and then they were able to ask questions to arrive at the correct diagnosis. Students were surveyed on the efficacy of patient-based learning.

Results: Average student scores on the differential diagnosis assignments significantly improved 32% during the course. From the survey, 72% of students felt that patient encounters should be included in the pathology course next year. 74% felt that the differential diagnosis assignments helped them develop clinical decision-making skills. 73% felt that the experience helped them know what questions to ask patients. 86% felt that they obtained a better understanding of patients' social and emotional challenges.

Discussion: Having students work through the process of differential diagnosis formulation when encountering a real patient and their clinical presentation improved clinical decision-making skills and integrated fundamental concepts with disease pathology during a basic science pathology course.

Patient exposure in the basic science classroom enhances differential diagnosis formation and clinical decision-making.

29 **Abstract**

30 **Purpose**

31 The authors proposed that introducing real patients into a pathology classroom early in medical
32 education would help integrate fundamental principles and disease pathology with clinical presentation
33 and medical history.

34 **Methods**

35 Three patients with different pathologies described their history and presentation without revealing
36 their diagnosis. Students were required to submit a differential diagnosis in writing, and then they
37 were able to ask questions to arrive at the correct diagnosis. Students were surveyed on the efficacy of
38 patient-based learning.

39 **Results**

40 Average student scores on the differential diagnosis assignments significantly improved 32% during
41 the course. From the survey, 72% of students felt that patient encounters should be included in the
42 pathology course next year. 74% felt that the differential diagnosis assignments helped them develop
43 clinical decision-making skills. 73% felt that the experience helped them know what questions to ask
44 patients. 86% felt that they obtained a better understanding of patients' social and emotional
45 challenges.

46 **Discussion**

47 Having students work through the process of differential diagnosis formulation when encountering a
48 real patient and their clinical presentation improved clinical decision-making skills and integrated
49 fundamental concepts with disease pathology during a basic science pathology course.

51 Introduction

52 A major challenge during medical school is making the leap from the basic science years to patient
53 encounters in the clinical setting. One difficulty involves forming differential diagnoses for a patient's
54 problem. Forming a differential diagnosis is critical to ordering proper clinical testing and
55 appropriately managing clinical disease. Unfortunately, most differential diagnosis education comes
56 during the third-year clerkships when the medical student is thrown into unfamiliar clinical situations
57 and responsibilities. Few attempts have been reported in the literature aimed at teaching differential
58 diagnosis and clinical decision-making in the early "basic science" years of medical education (Fulop,
59 1985; Duque, Gold & Bergman, 2003; Gesundheit et al., 2009; Jacobson et al., 2010; Gunning & Fors,
60 2012).

61 Some approaches in "early clinical exposure" have focused on the use of clinical cases and
62 standardized or virtual standardized patients to train medical students in clinical reasoning (Gesundheit
63 et al., 2009; Jacobson et al., 2010; Gunning & Fors, 2012). The use of clinical cases and standardized
64 patients has been well studied and documented in the medical education literature (Tamblyn et al.,
65 1991; TAMBLYN et al., 1991; Ainsworth, 1991; Colliver et al., 1998; Williams, 2004). While
66 standardized patients have a long history in medical education, their use also has identified problems,
67 including subjective biases in the standardized patients, inaccuracies, and unrealistic portrayals of
68 patient experiences (Tamblyn et al., 1991; Williams, 2004).

69 At the Mayo Medical School, we have been teaching differential diagnosis in the context of the
70 first-year Pathology course for a number of years. Students are taught how to form differential
71 diagnoses and begin the initial steps of clinical decision-making (Martin et al., 2014). In the past,
72 differential diagnosis was taught in the context of short patient cases that illustrated common human

73 pathologies. We wanted to try a pilot study to bring actual patients with true pathologies into the basic
 74 science classroom, early in undergraduate medical education, to see if students could delineate a
 75 differential diagnosis for their pathologies. We wanted to help students integrate fundamental
 76 principles of the basic sciences with a patient's clinical presentation, disease pathology, and course of
 77 disease. We also wanted to increase students' awareness of the important aspects of clinical histories
 78 and appropriate diagnostic testing or questioning in arriving at an accurate diagnosis. We hypothesized
 79 that actual patients with clinical pathologies would provide even more important learning with regard
 80 to clinical decision-making for the students.

81

82 **Materials and Methods**

83 This study was submitted to the Mayo Clinic Institutional Review Board for approval. It was
 84 determined in verbal communications not to require IRB approval, because it was conducted in the
 85 context of required assignments in an educational course.

86 In this pilot study, 47 first-year pathology students were introduced to three different volunteer
 87 patients with actual disease pathologies to present their clinical histories. The patients had previously
 88 expressed an interest in sharing their clinical history with medical students to faculty and staff at the
 89 clinic. The three patients came into the classroom on three different occasions during the course and
 90 spent approximately 30 minutes discussing the history and clinical scenario leading up to their
 91 diagnosis, without revealing their diagnosis. Immediately after the patient finished their history,
 92 students then completed an online assignment, which asked for their top three diagnoses (beginning
 93 with the most likely), an explanation of the aspects of the case that led to their most likely diagnosis,
 94 and additional questions or information that would help to confirm their differential (Figure 1). The

95 goal with the questions was not for the students to obtain the exact, true diagnosis, but for them to use
 96 their clinical reasoning skills to narrow down a reasonable differential diagnosis list based on the
 97 patient's history. We wanted the students to justify the rationale for their differential list and to
 98 formulate additional questions or tests that they would like to use to narrow down the differential list.
 99 Following submission of the online assignment, students were then permitted to ask the patients
 100 additional questions to determine the true diagnosis as a class. They were also given time to ask
 101 questions regarding the social, behavioral, economic, and other impacts of the disease on the patients'
 102 lives.

103 As the patient cases were not straightforward, simple, first-year cases, it was stressed to both
 104 the students and the teaching assistants that the goal of the assignments was not to obtain the exact,
 105 correct diagnosis, but to formulate a reasonable differential diagnosis list based on the patient's history.
 106 We specifically sought out patients with more complicated or multi-system diagnoses to expand the
 107 differential diagnoses that students could assemble for a given patient history. Consequently, the cases
 108 and the grading rubric allowed for a wider variability in the differential diagnoses compared with
 109 simpler medical case presentations. Teaching assistants utilized an established grading rubric and
 110 grading methodology used in other differential diagnosis assignments in the course to grade the
 111 assignments on an 18-point scale (Figure 1)(Martin et al., 2014). Student scores on the assignments
 112 were compared using ANOVA with Tukey–Kramer post-processing at the 0.05 α level.

113 At the conclusion of the course a survey was conducted among the students to determine the
 114 impact of patient encounters on their understanding of pathology, differential diagnosis formation,
 115 clinical reasoning, and patient empathy. The survey results were tallied on the basis of a five-point
 116 Likert scale. For simplicity in the summary table, strong and very strong agreement ratings were

grouped into the agreement column and strong and very strong disagreement ratings were grouped into the disagreement column.

Results

We piloted bringing volunteer patients with actual disease into a first-year pathology course to help students develop their differential diagnosis, history-taking, and basic clinical decision-making skills. The students' previous first-year courses included genetics, anatomy, and histology. The first volunteer patient presented his history of liver cirrhosis secondary to alpha-1 antitrypsin deficiency during the first week of the course. The differential assignments were graded by teaching assistants using the grading rubric shown in Figure 1 and using a previously described grading methodology (Martin et al., 2014). The first assignment resulted in an average score of 8.8 ± 3.1 out of 18 (Figure 2). During the pathology course, lectures, assignments, and teaching assistant feedback was devoted to helping students learn how to develop differential diagnoses, including the VITAMIN CDE methodology (Martin et al., 2014), how to ask appropriate questions of patients, and how to make basic diagnostic decisions.

The second volunteer patient was a pediatric patient who experienced a biliary leak and infection secondary to liver transplantation. The mother and patient presented the patient's history to the class approximately 3 weeks after the first patient. The second assignment resulted in an average score of 9.7 ± 2.7 (Figure 2), which was higher than the first assignment, but not significantly higher. Due to scheduling conflicts, the third patient presented his case of heart failure secondary to hypertrophic obstructive cardiomyopathy approximately one week after the second patient. The average score on this third assignment was 11.6 ± 2.7 , which was significantly higher than both the

first and second assignments, $p < 0.0001$ and $p = 0.0043$, respectively (Figure 2). We found that the students' grades on the patient encounter differential diagnosis assignments improved significantly by 32% over the course of the block (Figure 2).

At the end of the pathology block, students were asked to fill out a survey regarding their experiences with the patient encounter differential diagnosis assignments (Table 1). Overall, the students felt that the patient encounter experiences should be a continuing part of the pathology block and other first-year medical school courses (72.3% and 66.0%, respectively). Importantly, students strongly felt that the patient encounter experiences helped them develop clinical decision-making skills, know what questions to ask patients, and understand social and emotional challenges that patients face during disease (74.5%, 74.5%, and 87.2%, respectively). Interestingly, the students still indicated that they did not feel more comfortable facing patient encounters in the clinic after these experiences (27.7%). Students also indicated that they would have liked to have had patients with simpler, more common pathologies than those presented (data not shown).

Discussion

In this study, we have demonstrated that real patient encounters in the basic science classroom coupled with assignments aimed at clinical decision-making may improve clinical skills and help to provide clinical context to the basic sciences they are learning. We have shown that actual, volunteer patients can be brought into a first-year, basic science classroom to serve as patient educators, helping students learn to ask the right questions, formulate differential diagnoses, and understand the nonmedical challenges that patients endure. We believe that this coupling of the basic and clinical sciences in the

early years of medical school is important to help students more readily and confidently transition from the classroom to the clinical setting.

Other institutions have provided beginning medical students with early clinical exposure, through the use of clinical case scenarios and simulated patients (Fulop, 1985; Duque, Gold & Bergman, 2003; Gesundheit et al., 2009; Jacobson et al., 2010; Gunning & Fors, 2012). The challenge with these simulated experiences lies in their very nature, namely, they are simulated or artificial experiences (Tamblyn et al., 1991; Williams, 2004). Actual patient encounters provide realistic exposure to clinical scenarios. They can provide clinical context and psychosocial factors that cannot be considered in typical standardized patient scenarios. We did not focus on the students coming up with the exact, correct diagnosis at this early stage, because we felt that the process involved in formulating and justifying a reasonable differential diagnosis list is more important in early medical education. In particular, we wanted students to broaden their differential in the context of the pathology that they were learning about in the course.

Another benefit of real patient exposure in the early medical school years lies in the development of empathy or emotional IQ. While not directly assessed in this study, an overwhelming percentage of students did report a greater appreciation for the social and emotional challenges that patients endure. It is not clear that the same increase in empathy could be obtained from simulated patient experiences (Colliver et al., 1998). Empathy or emotional IQ is an important attribute of professional physicians, particularly, with many studies showing a decline in empathy over the course of medical education (Neumann et al., 2011).

We understand that our study is limited in that it was a pilot study for bringing actual patients into the basic science classroom. We only were able to recruit the three patient volunteers during the

182 first round of recruiting. While we felt that each patient scenario was appropriate for allowing students
 183 to create a reasonable differential diagnosis list, we were not able to choose from among a wide variety
 184 of patient scenarios. We also encountered some of the challenges in dealing with actual patients rather
 185 than simulated patients, in that we were not able to decide when students would encounter patient
 186 scenarios due to patient schedules. We also did not have fine control over how much or how little the
 187 patients would discuss about their cases. The patients were instructed to give as much pertinent history
 188 as they could without revealing the actual diagnoses being assessed. In the future, we hope to have a
 189 larger pool of volunteer patients from which to decide the most appropriate patient encounters at
 190 regular intervals during the course.

191 Interestingly, although students felt that the patient encounters increased their clinical decision-
 192 making skills and helped them to know what types of questions to ask patients, many students still did
 193 not feel an increase in confidence in dealing with patients (Table 1). Understanding that these students
 194 are still first-year students, it would be interesting to know what knowledge, skills, and experiences
 195 students require to feel confident going into clinical patient scenarios. It would also be interesting to
 196 see how the patient educators would rate students with regards to empathy or emotional IQ during
 197 these sessions to work on improving this professional characteristic. Unfortunately, in this study, we
 198 did not collect a grade breakdown for the different grading rubric criteria from the teaching assistants,
 199 only a total grade for the assignment. In the future, we would like to understand what specific areas
 200 showed the most improvement during the course, i.e. differential formation, differential justification, or
 201 clinical decision-making. Lastly, we would like to develop objective means to determine if the skills
 202 taught in this course are being implemented in the clinical setting.

203

204 **Conclusions**

205 Introducing actual patients into a first-year, basic science pathology classroom helped students to
 206 develop differential diagnosis formation, history-taking, and basic clinical decision-making skills at an
 207 early stage of undergraduate medical education. Students also reported that they were better able to
 208 understand and appreciate the challenges that patients face during the course of their disease.

Figure 1

Figure 1. Questions and grading rubric for patient encounters.

The patient encounter questions given to the students are seen in black type, while the grading rubric is seen in red type.

Patient Encounter Grading Rubric (18 points possible)

Given the clinical presentation you have just heard:

1) What are your top three diagnoses, in order, beginning with the most likely? (8 pts. possible)

1. 0-2 points (2 = excellent likelihood, 1 = good/likely, 0 = unlikely/blank)

2. 0-2 points (2 = excellent likelihood, 1 = good/likely, 0 = unlikely/blank)

3. 0-2 points (2 = excellent likelihood, 1 = good/likely, 0 = unlikely/blank)

For #1, most likely diagnosis, if it truly is the most likely diagnosis out of the three possible diagnoses give 1 point.

If #1 is the correct diagnosis give 1 more point

2) What aspects of the case lead you to your most likely diagnosis? (1-2 sentences) (4 points possible)

For each aspect of the history that corroborates with their most likely (#1 above) diagnosis, give 1 point. up to a maximum of 4 points. For each incorrect aspect cited, subtract 1 point.

3) What other questions/information do you believe would help you confirm/justify your differential? (3-4 questions) (6 points possible)

0-2 points (2 = excellent question/info to confirm diagnosis, 1 = good ques/info, 0 = poor/blank ques/info)

0-2 points (2 = excellent question/info to confirm diagnosis, 1 = good ques/info, 0 = poor/blank ques/info)

0-2 points (2 = excellent question/info to confirm diagnosis, 1 = good ques/info, 0 = poor/blank ques/info)

Table 1 (on next page)

Table 1

Table 1. Survey summary for student survey regarding patient encounter experiences.

Survey statistics are listed as percentages of the total class responses (N = 47). Likert scores of strong/very strong agree (4/5) are grouped together in agreement column, Likert scores of strong/very strong disagree (1/2) are grouped together in disagreement column, and the rest (Likert score 3) are in the neutral column.

Survey Statement	Agreement	Neutral	Disagreement
Patient encounters should be incorporated into the Pathology block next year.	72.3	12.8	14.9
More patient encounters should be included in the first-year courses.	66.0	17.0	17.0
The DDX assignments associated with the patient encounters help me develop differential diagnosis formation skills.	57.4	17.0	23.4
The DDX assignments associated with the patient encounters helped me develop clinical decision-making skills.	74.5	10.6	14.9
I have a better understanding of pathology through the patient encounter experiences.	53.2	21.3	25.5
The patient encounters helped me to better link a patient's pathology with the patient's clinical presentation.	68.1	14.9	14.9
The patient encounters helped me to better recognize key elements of clinical history and exam in a patient.	66.0	23.4	10.6
The patient encounters improved my confidence to interact with patients.	27.7	31.9	40.4
The patient encounters gave me a better sense of what questions would be important to ask patients.	74.5	12.8	12.8
The patient encounters gave me a better sense of what diagnostic procedures or test to order for patients.	63.8	6.4	29.8
The patient encounters gave me a better appreciation of the social and emotional challenges that patients go through.	87.2	8.5	4.3
The patient encounters helped to give you insight into what your clinical experience might be like.	68.1	19.1	10.6
