

Autonomous Sensory Meridian Response (ASMR): A flow-like mental state

Emma Barratt, Nick J Davis

Autonomous Sensory Meridian Response (ASMR) is a previously unstudied sensory phenomenon, in which individuals experience a tingling, static-like sensation across the scalp, back of the neck and at times further areas in response to specific triggering audio and visual stimuli. This sensation is widely reported to be accompanied by feelings of relaxation and wellbeing. The current study identifies several common triggers used to achieve ASMR, including whispering, personal attention, crisp sounds and slow movements. Data obtained also illustrates temporary improvements in symptoms of depression and chronic pain in those who engage in ASMR. A high prevalence of synaesthesia (5.9%) within the sample suggests a possible link between ASMR and synaesthesia, similar to that of misophonia. Links between number of effective triggers and heightened flow state suggest that flow may be necessary to achieve sensations associated with ASMR.

15 Introduction

16 In recent years, there has been growing interest in a previously unknown sensory phenomenon, named
 17 Autonomous Sensory Meridian Response (ASMR) by those capable of experiencing it. Those who
 18 describe ASMR claim it to be an anomalous sensory experience which has thus far escaped the eye of
 19 scientific research. There is a suggestion that ASMR may be of use for providing temporary relief to
 20 individuals with depression, stress and chronic pain. As ASMR has received some media attention in
 21 recent months, many have taken to public forums to explain their ability to induce ASMR to ease
 22 symptoms of these conditions in cases where other routes of treatment may have been lacking or
 23 ineffective (Taylor, 2013; TheWaterwhispers, 2013), while others use ASMR exclusively as a
 24 relaxation tool (Marsden, 2012). To date there has been no rigorous scientific exploration of ASMR,
 25 nor of the conditions which trigger or end the ASMR state.

26 Media designed specifically to produce ASMR has amassed a community of thousands of members.
 27 Capable individuals utilise a variety of visual and audio stimulation – most typically through video
 28 sharing – to achieve a tingling, static-like sensation widely reported to spread across the skull and
 29 down the back of the neck (Taylor, 2014). The advent of online video communities has facilitated a
 30 gathering of those who experience ASMR, and as a result hundreds of videos have been produced,
 31 viewed and shared with the goal of inducing this sensation, which is said to be paired with a feeling of
 32 intense relaxation. A dedicated ASMR subgroup on Reddit (<http://www.reddit.com/r/asmr/>) boasts
 33 86,000 subscribers from around the world, and some of the most popular ASMR content creators on
 34 video sharing site Youtube (<http://youtube.com/>), for example GentleWhispering have upwards of
 35 300,000 subscribers. Table 1 lists a number of these popular sources on Youtube. These figures show
 36 that the culture surrounding ASMR is in no way insignificant. Several reputable international media
 37 outlets have reported on the attention this phenomenon is receiving, and the lack of scientific
 38 explanation. (Marsden, 2012; Tomchak, 2014).

39 Though stimuli used to induce ASMR are widely varied, and devotees report that individual
 40 differences play a pivotal role in the effectiveness of each video, distinct themes appear to be present in
 41 ASMR media. Exploration of the most viewed ASMR media on Youtube uncovers what may be
 42 discrete categories of common triggers. For example, many of these videos depict role play situations,
 43 in which the viewer is placed in a position of ‘close proximity’ to another person in order to be cared
 44 for in some manner. Often this involves grooming (e.g. MassageASMR; Fairy Char ASMR), or being

45 given some type of medical examination (e.g. WhisperTalkStudios). The tone of these types of ASMR
 46 media is usually one of having close attention paid to you, the viewer, with videos shot in a point of
 47 view manner. Other videos include acts which require a similar amount of focus, but directed towards
 48 objects, rather than the viewer (e.g. Ephemeral Rift).

49 ASMR videos also typically appear to include an emphasis on the use of sound to trigger the static
 50 sensation of ASMR, which include the subjects of these videos cycling through a variety of household
 51 items which make various noises when tapped upon or used (e.g. MassageASMR). On the surface, this
 52 trigger resulting in sensation seems quite similar to the experience of synaesthesia, a phenomenon in
 53 which specific external stimuli cause an internal experience in a second, unstimulated modality
 54 (Banissy, Jonas & Cohen-Kadosh, 2014). . The reported automatic, consistent response to audio-visual
 55 stimuli which is felt in tactile sensory modalities alongside a feeling of calm does appear to resemble
 56 synaesthesia in these aspects, though the tactile concurrents (secondary sensations in the unstimulated
 57 modality; Cytowic, 2002) found in ASMR appear to be more tangible than those experienced in
 58 synaesthesia (ie. tingling on the skin). Even with this being the case, the positive emotional response of
 59 calm said to be triggered by ASMR media consumption could potentially be considered a form of
 60 sound-emotion synaesthesia.

61 Reports of ASMR experiences also appear to share some features with the state of “flow”, which is the
 62 state of intense focus and diminished awareness of the passage of time that is often associated with
 63 optimal performance in several activities, including sport (Csikszentmihalyi, 1991; Swann et al., 2014).
 64 Anecdotal reports of ASMR describe states of focus, of greater “presence” and of relaxation which are
 65 consistent with the non-active aspects of flow.

66 The aim of the current study was to describe the sensations associated with ASMR, explore the ways in
 67 which it is typically induced in capable individuals, and to provide further thoughts on where this
 68 sensation may fit into current knowledge on atypical perceptual experiences. This research also aims to
 69 explore the extent to which engagement with ASMR may ease symptoms of depression and chronic
 70 pain. As ASMR has yet to be defined within scientific literature, this study will utilise survey data and
 71 qualitative descriptive contributions from participants to explore the characteristics of ASMR, and to
 72 provide a basis for later experimental investigation.

73 **Materials and Methods**

74 Participants

75 The sample of the present study was comprised of 245 men, 222 women and 8 individuals of non-
76 binary gender (N=475). These participants presented themselves as volunteers via online advertisement
77 on specialised ASMR interest groups on Facebook and Reddit. The age of the sample ranged from 18
78 to 54 years (mean = 24.6 years, st. dev. = 7 years). Volunteers were located worldwide, with particular
79 participation from the United States of America and Western Europe. All individuals in the sample
80 self-reported to have experienced ASMR and regularly consume ASMR media.

81 Method

82 An online questionnaire (www.qualtrics.com, Version 36,892) was conducted in order to gather
83 information on the prevalence of particular features of ASMR, when and why individuals engage in
84 ASMR, and the relation of ASMR to other known phenomenon. Ethical approval was granted by the
85 Department of Psychology of Swansea University, and continuation from the initial screen of this
86 questionnaire, which contained a brief summary of the research topic and all necessary ethical
87 information, served as informed consent. The structure of this questionnaire is described below, and a
88 version of the text of the questionnaire is included as supplementary material:

89 *Section 1 - Demographics*

90 Demographic information, including whether or not individuals suffered from any chronic
91 illness or took medications, was gathered at the beginning of the survey. In addition, the Beck
92 Depression Inventory (BDI-II; Beck et al., 1996) and Beck Anxiety Inventory (BAI; Beck et al., 1988)
93 were included to give insight on the daily mood of participants. As several online sources indicate the
94 existence of a subset of ASMR media users who engage in ASMR to manage symptoms of depression,
95 stress, or pain, this data would be used to explore efficacy of ASMR in easing symptoms of these
96 conditions. Participants were asked to verify that they identified as able to experience ASMR and
97 the tingling sensations commonly associated with ASMR. No leading elaboration was given with
98 regard to this sensation, as all participants had been recruited via ASMR social network groups, and
99 would therefore be aware of how this aspect of the phenomenon is typically described. This was an
100 attempt to limit imposing researcher assumptions about ASMR. In this section, participants were also
101 given a definition of synaesthesia, alongside some examples of synaesthetic associations. Participants

were asked to report if they suspected they may experience any type of synaesthesia. Those who responded in a positive or unsure manner were asked to specify which type of synaesthesia they thought they may have, and were followed up approximately four weeks later via e-mail to be assessed for consistency.

Section 2 – Viewing Habits

This section included questions pertaining to how often participants engaged in ASMR media sessions, how many videos they consumed in a single session, and at what time of day they typically viewed ASMR media. Questions regarding the optimal conditions to experience ASMR were also included.

Section 3 – Triggers

Participants were asked to report whether or not they experienced any of the triggers in a list of 9 given stimuli: Crisp sounds, whispering, personal attention, vacuum noise, aeroplane noise, laughing, smiling, watching repetitive tasks, and slow movements. Of these suggestions, five possible triggers were inspired by the typical content of ASMR videos (eg. Close personal attention, crisp sounds) and four were unlikely triggers (vacuum noise, aeroplane noise, laughing, smiling). These unlikely triggers are commonly present in ASMR videos, but are not commonly identified in titles or online discussions, so were considered to be unlikely to produce tingles in many participants. This section included a comment box in which participants could specify what, if anything, abolished the tingling sensations. Preference of receiving auditory triggers in one ear over another was also probed.

Section 4 – Location

In order to more clearly define the location and time course of the tingling sensation associated with ASMR, participants were asked to report where on their body they typically felt tingles originate, and whether or not the sensation always originated in that area. Participants were also asked whether or not the tingling evolved or spread with intensity, and if so, which other body areas the tingling sensation spread to.

Section 5 – ‘Why do you watch ASMR videos?’

This section presented several likert style statements to be rated from ‘strongly agree’ to ‘strongly disagree’ in terms of how well each represented individuals’ experiences of ASMR and

ASMR media. These included statements concerning mood and arousal control, such as ‘I watch ASMR videos to relieve negative mood’, ‘... to deal with anxiety’, and ‘... to relieve stress’. Further, more generalised statements, such as ‘I know what triggers my ASMR’, ‘I watch ASMR videos for sexual stimulation’, and ‘ASMR videos help me focus’ were included to obtain a rounded view of why participants choose to engage with ASMR media.

Section 6 - Flow State Scale

Since the reported ASMR experience shares some features with that of the ‘flow’ state (Csikszentmihalyi, 1991), we used a reduced version of the Flow State Scale (Jackson & Marsh, 1996) to quantify this experience. We selected only the eight questions relating to the passive experience of flow. Participants scored their agreement with statements such as “Things seem to happen automatically” on a 5-point scale. These scores were initially subjected to factor analysis to confirm that only a single factor had been captured in the reduced questionnaire. Combined scores, composed of the sum of the scores of the components, were then submitted to Pearson’s Correlation to investigate links between flow state and trigger thresholds.

Section 7 - Effect on mood and chronic pain

Using an interactive sliding scale ranging from 0 to 100, participants were asked to rate their experience of mood during a typical day, directly before, during, one hour after and 3 hours after a successful ASMR media viewing session. These ratings were given at the same time, i.e. not during the ASMR state. 0 on this scale represented ‘terrible, the worst I’ve ever felt’, whereas 100 represented ‘euphoric, the best I’ve ever felt’. Participants who earlier indicated that they suffered from chronic pain were also asked to complete a version of this task with the intensity of their pain symptoms in mind.

Data analysis

Where possible, analyses were conducted on the entire sample (N=475). However, due to certain sections being inapplicable to some participants, some sections included data from a subset of the entire sample. In these cases, N is reported alongside the results. All analyses were carried out in SPSS and Microsoft Excel. A copy of the data from this experiment are included as supplementary data.

Results

158 *Why engage in ASMR?*

159 Through Likert style questions, participants largely sought out ASMR as an opportunity for relaxation,
160 with 98% of individuals agreeing, or agreeing strongly with this statement. In a similar vein, 82%
161 agreed that they used ASMR to help them sleep, and 70% used ASMR to deal with stress. A small
162 number of individuals (5%) reported using ASMR media for sexual stimulation, with the vast majority
163 of participants (84%) disagreeing with this notion.

164 Many participants described additional details of seeking the effects of ASMR where other
165 interventions, medical or otherwise, had been unable to assist. This is perhaps best illustrated by a
166 correspondence from one participant whose anxiety and stress was causing significant issues in his
167 daily functioning. After noticing during a hairdressing appointment that he felt at ease, he sought out
168 ways to replicate this feeling daily in order to manage his symptoms, and in the process discovered
169 ASMR media. In his own words:

170 *“I was totally amazed, I can only describe what I started feeling as an extremely relaxed trance like*
171 *state, that I didn’t want to end, a little like how I have read perfect meditation should be but I never*
172 *ever achieved.”*

173 *Common triggers*

174 Analysis of responses found four prominent categories of triggers, each experienced by over 50% of
175 participants. These triggers are whispering (75%), personal attention (69%), crisp sounds (64%) and
176 slow movements (53%). 34% of participants also reported that their ASMR was triggered by watching
177 repetitive tasks. Triggers less commonly associated with ASMR media (smiling, vacuum cleaner noise,
178 aeroplane noise, and laughing) were included for comparison. Each of these non-triggers were in each
179 case reported to be effective by less than 3% of participants. These values are illustrated in Table 2.
180 Some individuals reported only being triggered by new viewing material, in which they are unable to
181 predict which trigger will be presented next.

182 The most common time for engagement with ASMR media was reported to be before going to sleep at
183 night, with 81% of participants reporting this as their preferred time. 4% of participants engaged in
184 ASMR upon waking, 2% participated during the morning to midday. 30% of participants also reported
185 viewing ASMR media in their spare time, regardless of the time of day.

186 When asked if participants preferred any specific environmental conditions for viewing, 52%
 187 responded 'yes'. Submitted comments suggested that of these, individuals near universally preferred
 188 quiet, relaxed conditions in order to achieve ASMR from online media. Many also specified preference
 189 for binaural headphones, so as to experience depth of sound.

190 Most participants reported having their first experience of ASMR at age five (65 individuals), with the
 191 vast majority (241 individuals) reporting the first experience of ASMR between five and ten years of
 192 age. There were also several instances of ASMR being first experienced further into adulthood – 41
 193 individuals reported their first ASMR experience as happening after age 18.

194 195 *Experience of ASMR*

196 Participants widely reported sensations similar to that found in general reporting of ASMR; a tingling
 197 sensation which originated typically towards the back of the scalp and progressed down the line of the
 198 spine and, in some cases, out towards the shoulders. Many participants also felt that their lower back,
 199 arms and legs experienced the sensation, though the amount of area the tingles covered seemed to be
 200 determined by the extent to which individuals had been triggered.

201 63% of participants reported the tingling sensation associated with ASMR to originate consistently in
 202 one part of their body, while 27% said this origin varied. Of those that reported a consistent origin, the
 203 static tingling sensation was reported to typically originate on the back of the head (41%) and
 204 shoulders (29%). When intense, this sensation is able to extend down the line of the spine (50%), arms
 205 (25%) and legs (21%), though this does not occur in every session, and every individual does not
 206 experience the same route. An illustration of the most common path of these sensations is provided in
 207 Figure 1.

208 209 *Medications which affect ASMR*

210 Of the sample who reported taking medication, only three participants responded positively when
 211 asked if they had noted effects of any of their medications on ASMR. One participant noted that their
 212 antidepressant stifled sensations of ASMR, which later returned once they stopped taking the
 213 medication, though they did not specify which. Another noted that sleeping pills dulled their ASMR
 214 experience. A third reported that Clonazepam decreased the sensations associated with ASMR. Six

215 participants responded that their medication had no effect on ASMR. 103 other participants who use
216 medication were unsure as to the effect of their medication on their experience of ASMR.

217 *Effect on mood*

218 80% of participants responded positively when asked if ASMR has an effect of their mood, while 14%
219 were unsure and 6% felt that ASMR did not alter their mood. When submitted to a mixed ANOVA
220 with factors for time (before, during, immediately following and 3 hours after ASMR) and for
221 depression status (high, medium or low as defined by the BDI), we found a significant main effect of
222 time on mood [$F(3.06, 1143.0)$, $p < 0.0005$]. Pairwise comparisons revealed significant differences
223 between all timeframes ($p < 0.0005$ in all cases). Participants reportedly felt best while they are
224 engaging with ASMR media, with reports on the 0 to 100 scale of positive mood averaging at 78 for
225 this time period. The effect on mood steadily decreased over the course of several hours. Means for all
226 time frames are reported in Figure 2. This effect is moderated by severity of depression, with people at
227 higher risk of depression showing a more rapid decline in mood score over time [$F(10,2360)=20.217$, p
228 < 0.0005] however, there was also a correlation between BDI scores and the difference in mood score
229 between baseline and immediately after an ASMR experience, suggesting that people with higher
230 depression scores had the greatest benefit from engaging in ASMR [$r=0.439$, $p<0.0005$].

231 50% of participants said their mood improved even in sessions when no tingling sensation was
232 produced, while 30% said that achieving this sensation was vital to mood improvement.

233 69% of those who scored moderate to severe on the BDI reported using ASMR to ease their symptoms
234 of depression ($N=70$). Those scoring as depressed reported a mean improvement in mood of 38.75
235 (STD = 18.85), in comparison to a mean improvement of 21.33 (STD = 13.58) in non-depressed
236 participants.

237 *Effect on chronic pain*

238 38 individuals with chronic pain reported that ASMR improved their symptoms. 13 were unsure of
239 ASMR's impact on their symptoms. 40 did not believe that ASMR had an impact on their symptoms of
240 chronic pain. Analyses were carried out on the responses of individuals who responded positively and
241 unsurely to this section. Six individuals who originally reported issues with chronic pain were omitted
242 due to incomplete data. Data analysis was therefore carried out on 45 cases.

243 Self-report data for before, during, immediately after and 3 hours after ASMR were analysed using a
 244 one way ANOVA, and were found to significantly differ [$F(3, 132) = 13.892, p < 0.0005$]. Pairwise
 245 comparisons revealed there to be a significant difference in chronic pain symptoms before and during
 246 ASMR ($p < 0.0005$), a difference which was maintained three hours following ASMR ($p = 0.014$).
 247 There was no significant difference between symptoms of chronic pain during and immediately after
 248 ASMR ($p = 1.00$), nor was there a difference between during and 3 hours after ASMR ($p = 0.21$).

249 *Flow state*

250 50 cases did not have complete data for the flow state questionnaire, so were removed from analysis.
 251 We were interested in whether people who experience the flow state more readily also experience the
 252 ASMR state more readily. To examine this we took the sum of each participant's responses on the flow
 253 state questionnaire and correlated this with the total number of ASMR triggers each person reported,
 254 from the list of commonly-reported triggers (i.e. whispering, crisp sounds, personal attention, repetitive
 255 actions, slow movements, smiling, water pouring). We used a non-parametric Spearman's test, as the
 256 trigger data tended to fall into a small number of values. We found a highly significant relationship
 257 between flow experience and number of triggers, with greater flow experience being associated with a
 258 larger number of triggers [$\rho = 0.936, p < 0.01$]. This relationship is shown in Figure 3.

259 *Familial links*

260 When asked if they knew of any family members who experienced ASMR, 38 participants responded
 261 positively, 59 responded negatively, and the remaining 378 were unsure or had not inquired. The
 262 relations most often identified as experiencing ASMR were sisters (17 individuals), mothers (11),
 263 brothers (7) and fathers (4). There were also reports of grandparents experiencing ASMR, though as
 264 relational distance increased fewer individuals were reported to be known as able to experience ASMR.
 265 It is likely that the perceived strangeness and stigma many individuals feel surrounds ASMR, has
 266 prevented many from asking if other individuals within their family experience something similar. The
 267 reports gathered through this research, however, do appear to indicate a familial aspect to the ability to
 268 experience ASMR.

269 *Synaesthesia*

270 Synaesthesia appeared to be particularly prevalent within the sample. 35 participants reported
 271 experiencing various subtypes synaesthesia and, after exploration of the consistency of concurrents
 272 through a follow up interview, 29 of these cases were assessed to be genuine. This places the
 273 prevalence of synaesthesia within the sample at 5.9%, compared the current estimate of prevalence in
 274 the general population of 4.4% (Simner et al. 2006), however, our value fell slightly short of being
 275 significantly higher than the general population ($Z=1.594$, $p=0.0555$). Participants reported several
 276 subtypes, including grapheme-colour, grapheme-personality, time-space and pain-gustatory
 277 synaesthesia.

278 Some comments submitted seem to resemble the inducer-concurrent relationship in synaesthesia. One
 279 individual described the tingling sensation as changeable depending on the gender of the voice in the
 280 ASMR video she was currently watching. She reported that a female voice would cause the tingles to
 281 extend more strongly down one leg, whereas a male voice would increase the sensation in the other leg.
 282 Several individuals responded similarly, specifying that '*different triggers hit different parts*'. However,
 283 without more data it is difficult to ascertain whether similar experiences are common amongst ASMR
 284 capable individuals.

285 Discussion

286 ASMR can be defined as a combination of positive feelings, relaxation and a distinct, static-like
 287 tingling sensation on the skin. This sensation typically originates on the scalp in response to a trigger,
 288 travelling down the spine, and can spread to the back, arms and legs as intensity increases. An increase
 289 in intensity can be achieved through experiencing further triggers.

290 Those who are able to can engage in ASMR through specialised media at any time, given that the
 291 environment in which they attempt to do so is quiet and calm. Many report being triggered by viewing
 292 others engaged in focused, precise tasks, by having close personal attention paid to them, or by any
 293 number of audio stimuli, such as whispering, tapping or other crisp sounds. Though the effectiveness
 294 of various triggers is subject to individual differences, most who experience ASMR can be induced by
 295 the above categories of stimuli, either through watching specially designed media, or by coming across
 296 triggers in daily life. In capable individuals, ASMR is used mainly to achieve relaxation and for stress
 297 relief purposes.

298 *Uplifting mood and pain relief*

299 The results of this study suggest that ASMR also provides temporary relief in mood for those suffering
 300 from depression, with many individuals consciously using it for this purpose. Individuals whose scores
 301 on the BDI suggested moderate to severe depression reported a significantly more uplifting effect of
 302 engaging in ASMR than those without depression. Those suffering from symptoms of chronic pain also
 303 benefitted from ASMR, seeing a significant reduction in their discomfort for several hours following
 304 an ASMR session.

305 Many reported that even in the absence of tingling sensations, they felt that their mood and symptoms
 306 of pain had been improved. It is possible that devoting specific time to engaging in ASMR, watching
 307 relaxed scenes play out and sitting quietly could be considered a form of mindfulness (Langer, 1989).
 308 Those who engage in ASMR take time to focus on positive emotions triggered by these stimuli,
 309 focusing exclusively on this the task at hand. This behaviour is very reminiscent of mindfulness
 310 practices, which have already been shown by several studies to have positive effect on both conditions
 311 (Kabat-Zinn, Lipworth & Burney, 1985; Segal, Williams & Teasdale, 2012). This categorisation of
 312 ASMR as an exercise in mindfulness meditation perhaps best explains the improvements in mood
 313 observed in both depressed and non-depressed participants in this study.

314 *Obtaining Flow State*

315 Individuals who scored highly on flow measures reported regularly experiencing a higher number of
316 triggers. This suggests that those who are able to more readily experience flow state during ASMR
317 media consumption are susceptible to more frequent ASMR experiences during their sessions.

318 Many ASMR videos show individuals in highly focused states (e.g. performing medical exams) or
319 engaged in repetitive tasks (e.g. folding towels). The behaviour of performers during these types of
320 videos often resembles that of someone in flow state – confidently and accurately executing precise
321 tasks. It may be that ASMR is brought about by obtaining a flow-like state, which is in part facilitated
322 by witnessing others in such a state. Similar transference of state from performers to audience have
323 been observed in studies probing the role of mirror neurons (Rizzolatti, Sinigaglia & Anderson, 2008).
324 Higher levels of flow may in turn facilitate triggers to be obtained, as could be indicated by results of
325 this study.

326 *Links with synaesthesia*

327 The prevalence of synaesthesia of any type within the current study's sample was 5.9%, which is high
328 for the estimated prevalence of 4.4% in the general population (Simner & Hubbard, 2013). Although
329 the figure reported here did not exceed the estimated level to a statistically significant degree, we
330 would suggest there may be a relationship between the two phenomena. In emotional subtypes of
331 synaesthesia, individuals feel moved to various emotions by inducing stimuli which should, in theory,
332 have no emotional effect on them (e.g. tactile-emotion synaesthesia; Ramachandran & Brang, 2008).
333 This sounds strikingly similar to the experience of emotion in ASMR, where emotionally neutral
334 sounds such as tapping and paper tearing, or visual stimuli such as tasks requiring close concentration,
335 bring about a consistent relaxing, stress relieving, positive emotional response.

336 It is, however, also worth exploring whether or not the experience of ASMR ends with automatic
337 positive emotional reactions to neutral audio and visual stimuli. There may also be merit in exploring
338 automatic negative emotional reactions to external stimuli, and assessing any relation of such an
339 experience to ASMR. Within literature surrounding synaesthesia, a related phenomenon that fits this
340 description does exist, and is known as misophonia. Those who experience misophonia (literally
341 'hatred of sound') have automatic negative emotional reactions to particular sounds – the opposite of
342 what can be observed in reactions to specific audio stimuli in ASMR. For instance, sufferers report that

noises made by humans, such as ‘loud breathing or nose sounds’ of any volume can produce feelings of disgust, anger, or hatred in a manner which cannot be explained by previously learned associations. (Schröder, Vulink & Denys, 2013) Though this condition has not yet been included in the Diagnostic and Statistical Manual (DSM), there has been movement for misophonia to be recognised as a psychiatric disorder in future revisions, and links between this phenomenon and other perceptual atypicalities such as synaesthesia have been found (Edlstein, Brang & Ramachandran, 2012).

There are distinct similarities between the experience of ASMR and Misophonia. In both phenomena, triggering sounds originate from human movements and behaviours. Reactions to these stimuli automatic in both cases, unexplained by previously learned associations, and have some consistency (with the possible exception of some individuals becoming habituated to triggers from ASMR media they have previously viewed). The present study suggests that ASMR, similarly to misophonia, may have a relationship with synaesthesia. Indeed, both experiences seem to follow somewhat synaesthetic patterns; particular inducers (external stimuli, such as whispering, close attention, etc.) produce concurrents (internal perceptual/sensational experiences - in the case of ASMR, tingling and relaxation) in a somewhat predictable manner. It may be the case that ASMR and misophonia are two ends of the same spectrum of synaesthesia-like emotional responses. Whether this hypothetical spectrum, or indeed ASMR alone, can be classified as a type of sound-emotion synaesthesia is however, debateable.

The main issue with relating ASMR to synaesthesia is that, from the data collected here, there does appear to be a difference between the two in terms of tangibility of concurrents. Whereas synaesthetic concurrents are described as ‘having a knowledge or sensation of a certain concurrent’ (Simner & Hubbard, 2013), the tingling sensation associated with ASMR is described in a very physical sense. If we were to consider the concurrent of ASMR as a tingling sensation, as described by participants of the current study, we could with near certainty say that ASMR is not a subtype of synaesthesia. However, this neglects the presence of positive emotions which accompany the tingling sensation. It may be that ASMR is the positive end of a spectrum of a sound/emotion synaesthesia, and that this tingling sensation is a secondary phenomenon resulting from intensely positive feelings, rather than the primary concurrent. The data collected seems to support this, as many participants reported feeling relaxation and positive emotions even in the absence of a tingling sensation.

372 However, there is no mention in misophonia research of any negative counterpart to the tingling
 373 sensation found in ASMR. If one were looking for a truly polar opposite sensation, it may be expected
 374 to observe numbness in the skin or an irritating sensation present. It must be considered, however, that
 375 perhaps the opposite of this tingling sensation is not irritation, but actually the general level of
 376 sensation that might be expected in typical individuals. Rather than this aspect lying on a continuum
 377 from irritation to typical sensation to pleasant tingling, it is a smaller continuum between typical
 378 sensation and pleasant tingling, with many shades of grey between the two.

379 *Future directions for research*

380 Though the age of the sample in the present study suggests engaging in ASMR is primarily an
 381 endeavour of young adults - this is likely to be reflective of limitations in the sampling method. Several
 382 individuals above age 40 provided input via this questionnaire, and some participants spontaneously
 383 reported being aware that one of their parents and/or their children also experienced what they believe
 384 to be the same the sensation. This would suggest that the young age of the sample is more likely a
 385 product of user demographic of Facebook and Reddit than an accurate representation of ASMR
 386 capable individuals' ages. In the current study, synaesthesia was tested for consistency via e-mail
 387 interview. As the subtypes reported by participants were so varied, some immeasurable by the standard
 388 Test of Genuineness (TOG-R; Asher et al., 2006), interview was favoured over electronic tests of
 389 consistency such as those found on synaesthete.org (Eagleman et al., 2007). We suggest that future
 390 studies into ASMR include rigorous controls for synaesthetic experience.

391 While ASMR appears to be a genuine, relatively prevalent perceptual experience, the exact nature of
 392 the phenomenon is still unknown. There is the possibility that the tingles associated with ASMR result
 393 from a minor seizure, brought on by appropriate stimuli. This has been hypothesised in the past
 394 (Novella, 2012), but as of yet remains uninvestigated. In this vein, research utilising neuroimaging
 395 methods such as fMRI may further our understanding brain regions involved in ASMR. fMRI
 396 investigations in particular, however, have potential to prove problematic, as results of the current
 397 study show that individuals overwhelmingly require specific, quiet and relaxed conditions to achieve
 398 the desired sensation. An alternative avenue of research might be the use of so-called non-invasive
 399 brain stimulation (Davis & van Koningsbruggen, 2013) to modulate brain activity during ASMR.
 400 Techniques such as transcranial direct current or magnetic stimulation (tDCS, TMS) are known to
 401 induce multisensory experiences, often as an unintended side-effect of stimulation (Davis, Gold,

402 Pascual-Leone, & Bracewell, 2013). Given the age demographic of ASMR consumers, we note that
403 brain stimulation techniques should be used sparingly in younger people (Davis, 2014).

404 Further exploration into ASMR's relationship with Misophonia may also yield interesting results.
405 Studies examining the co-occurrence of Misophonia and ASMR may shed more light on the possibility
406 that these two experiences are related, or potentially opposite poles of the same spectrum. Similarly,
407 the relationship with synaesthesia suggested by the results of this research should be taken further,
408 using more robust consistency measures to verify that the high instance of synaesthesia in ASMR
409 capable individuals. The suggestion that ASMR and Misophonia may be related was based primarily
410 on similarities in reaction to auditory stimuli. Though sounds play a pivotal role in ASMR, it would
411 also be advantageous to investigate the role of visual stimuli alone in triggering viewers, as such
412 stimuli involving precise movements and focused tasks appear to be effective while being near silent.

413 *Conclusions*

414 We have provided the first investigation into the phenomenon of autonomic sensory meridian response
415 (ASMR). ASMR can be induced, in those who are susceptible, by a fairly consistent set of triggers.
416 Given the reported benefits of ASMR in improving mood and pain symptoms, we suggest that ASMR
417 warrants further investigation as a potential therapeutic measure similar to that of meditation and
418 mindfulness.

Table 2 (on next page)

Common Triggers

Table 2 - Percentage of participants that reported induction of tingling sensations from each trigger type.

2 Table 1 - Percentage of participants that reported induction of tingling sensations from each trigger type

Trigger type	Percentage of participants triggered
Whispering	75%
Personal attention	69%
Crisp sounds (metallic foil, tapping fingernails, etc.)	64%
Slow movements	53%
Repetitive movements	36%
Smiling	13%
Aeroplane noise	3%
Vacuum cleaner noise	2%
Laughing	2%

ASMR Map

Figure 1: An illustration of the route of ASMR's tingling sensation. Image shows rear view of the head and upper torso. Capable individuals typically experience the sensation as originating at the back of the head, spreading across the scalp and down the back of the neck. Half of participants reported that this sensation typically spreads to the shoulders and back with increasing intensity. Though this diagram represents the most common areas involved in the tingling sensation, there is a huge amount of individual variation in where tingles spread to with increased intensity, with legs and arms also commonly reported as hotspots in some individuals.

2

BDI graph

Figure 2: The time course of mood before, during, immediately following, and several hours after engaging in ASMR. Data shown is the mean mood score given to each time frame by all participants (N = 475), with participants grouped according to their Beck Depression Index. Mood scores could range from 0 to 100, 0 representing the worst the individual had ever felt, 100 representing the best they have ever felt. Error bars represent +/- 1 standard error.

3

Flow and Triggers figure

Figure 3 - Relationship between participants' susceptibility to the flow state (expressed as a sum of the scores on the modified Flow State Scale) and the number of triggers of the ASMR state.
