Background: Oral mucosal diseases (OMDs) refer to the various types of diseases. Our aim was to evaluate the prevalence and related risk factors of OMDs among residents in Baoshan District of Shanghai and provide a scientific basis for prevention and control strategies.

Methods: Oral Assessment Form, WHO and oral examinations were conducted in Baoshan District of Shanghai selected by cluster sampling, 653 residents aged from 17 to 92 years old were investigated. Four years later follow-up. X2 test was used to compare the rates. Logistic regression analysis was used to detect the risk factors.

Results: The prevalence rate of OMDs was 9.04-9.56% (2014-2018). The most common OMDs were atrophic glossitis (1.84%), recurrent aphthous ulcer (RAU, 1.68%), burning mouth syndrome (BMS, 1.38%), oral lichen planus (OLP, 1.23%), traumatic ulcers (1.23%). The prevalence of RAU and BMS in different age groups was significantly different. Tobacco and alcohol use and psychological factor in OMDs group were higher than the no-OMDs group. System disease including diabetes mellitus (DM) was relevant to OLP.

Conclusion: Age, tobacco and alcohol use, and psychological factor correlated with the occurrence and development of OMDs, and they should be the focus of primary prevention. General epidemiological studies suggested that OLP was closely related to DM.

27

28 **Abstract**

29 **Background:** Oral mucosal diseases (OMDs) refer to the various types of diseases. Our aim
30 was to evaluate the prevalence and related risk factors of OMDs among residents in Baoshan
31 District of Shanghai and provide a scientific basis for prevention and control strategies.

32 **Methods:** Oral Assessment Form, WHO and oral examinations were conducted in Baoshan
33 District of Shanghai selected by cluster sampling, 653 residents aged from 17 to 92 years old
34 were investigated. Four years later follow-up. X^2 test was used to compare the rates. Logistic
35 regression analysis was used to detect the risk factors.

36 **Results:** The prevalence rate of OMDs was 9.04-9.56% (2014-2018). The most common
37 OMDs were atrophic glossitis (1.84%), recurrent aphthous ulcer (RAU, 1.68%), burning mouth
38 syndrome (BMS, 1.38%), oral lichen planus (OLP, 1.23%), traumatic ulcers (1.23%). The
39 prevalence of RAU and BMS in different age groups was significantly different. Tobacco and
40 alcohol use and psychological factor in OMDs group were higher than the no-OMDs group.
41 System disease including diabetes mellitus (DM) was relevant to OLP.

42 **Conclusion:** Age, tobacco and alcohol use, and psychological factor correlated with the
43 occurrence and development of OMDs, and they should be the focus of primary prevention.
44 General epidemiological studies suggested that OLP was closely related to DM.

49

50 **Introduction:**

51 Oral mucosal diseases (OMDs) occur in the oral mucosa and soft tissues and are related to
52 general health (Porter et al., 2017). The kinds of OMDs are various; The etiology is unknown,
53 the course of disease is difficult to cure, easy to relapse, and is closely related to systemic
54 diseases and physical and mental. Some diseases have potential malignancies that seriously
55 affect quality of life and even are fatal. Oral Potentially Malignant Disorders (OPMDs) refers to
56 diseases that may cause oral cancer (Wang et al., 2014; Dionne et al., 2015). OLP is the most
57 common clinical OPMDs, with a cancerous rate of 0% to 12% (van der Meij et al., 2003). Oral
58 leukoplakia (OLK) is the most important OPMDs, with a cancerous rate of 10-30% and an
59 average cancerous time of 4-8.1 years (Petti, 2003; Warnakulasuriya et al., 2011). Oral
60 erythroplakia (OE) is the most cancer-prone OPMDs, with a cancer rate as high as 50% (Villa et
61 al., 2011).

62 Most of the causes of OPMDs are complex, and their pathogenesis and cancerous
63 mechanism are unclear. Generally, there are no specific treatments and no effective chemical
64 prophylaxis drugs for cancer (Ribeiro et al., 2010; van Monsjou et al., 2013). Poor prognosis of
65 OPMDs and the condition of multiple and recurrent cancers can cause great physical and mental
66 pain to patients. Early diagnosis of OPMDs with high risk of cancer is of great significance for
67 the prevention of oral malignant tumors (McCullough et al., 2010; Amagasa et al., 2011).

68 As global megacity, Shanghai has a population of more than 24 million. Therefore, it is
69 of great significance to understand the epidemiological characteristics of OMDs and analyze the
70 risk factors associated with diseases. So as to early prevention and treatment of OMDs, early
71 detection of high-risk groups of oral cancer, and improve people's quality of life.

72 The prevalence of OMDs was studied in a cross-sectional study using general
73 epidemiology. The subjects were selected from the general population or oral outpatients. The
74 former is a large sample survey of oral mucosal diseases in the population (current situation
75 survey), and there are few data reports at present. In the recent 30 years, the epidemiological
76 investigations of OMDs are mostly based on the investigation and analysis of clinical data of

77 patients, or case-control studies (Ikeda et al., 1995; Mumcu et al., 2005; Splieth et al., 2007;
78 Pentenero et al., 2008; Mansour Ghanaei et al., 2013; Do et al., 2014).

79 Because of the low incidence of OMDs and large sample size in the survey, it is
80 necessary to have professional theoretical knowledge and sufficient clinical experience in order
81 to make an accurate diagnosis. Little work has been done in the epidemiology of OMDs,
82 especially descriptive epidemiology. However, most are investigations of specific age groups or
83 special diseases (Xu et al., 1981; Qi, 2008). Work stress, mental stress, environmental changes,
84 dietary changes and accelerated life rhythms will inevitably lead to some changes in the
85 prevalence of OMDs.

86 In this study, the epidemiological characteristics of oral mucosal diseases in Baoshan
87 district of Shanghai were studied, and the risk factors of the diseases were analyzed, so as to
88 understand the incidence rate and epidemic characteristics of oral mucosal diseases in Baoshan
89 district of Shanghai, and provide scientific basis for the prevention and treatment of oral mucosal
90 diseases.

91

92 **Materials and Methods:**

93 *Research Objectives*

94 We used the ways of multistage stratified random sampling and field survey to investigate the
95 samples at the year of 2014 in Baoshan district of Shanghai. The long-term effects of persistent
96 risk factors on the disease of the same patient were analyzed by longitudinal observation of the
97 same group of community residents during a follow-up period of 4 years.

98 *Questionnaire design and Oral mucosa examination*

99 Informed consent was obtained prior to the initiation of the examination. Prior to the study,
100 inspectors were trained and calibrated to ensure uniform interpretation of the guidelines for
101 observation and documentation of various mucosal diseases.

102 Our survey form was prepared according to the oral health assessment form of WHO (2013)
103 (World Health Organization, 2013). It was used in this study to evaluate oral mucosa. The

104 questionnaire includes demographics (name, gender, age, nationality, place of birth, length of
105 residence in Shanghai, education level, marital status, occupation, etc.), smoking, drinking
106 habits, eating habits, health status (systemic disease, heredity), and mental status (stress,
107 anxiety).

108 According to WHO, when performing oral mucosa examination, the intraoral and perioral
109 mucosa and soft tissue should be examined for each subject. The examination should be
110 comprehensive and systematic, in order of lip, corner of mouth, cheek, tongue, bottom of mouth,
111 hard and soft palate, alveolar ridge and gingiva.

112 ***Statistical methods:***

113 All data were statistically analyzed using SPSS 25.0 software package (Chicago, IL, USA). The
114 data were input computer by two persons (two copies) to describe and analyze the data of the
115 general population, gender and age stratification. X^2 test was used to compare the rates. Logistic
116 regression analysis was used to detect the correlation between disease and risk factors when
117 making statistics of binary variables such as risk factors related to OMDs. Results were
118 considered significant if $P < 0.05$.

119

120 **Results:**

121 ***Information of investigative patients***

122 The residents were 653 samples (male 337, female 316). The investigative patients' education
123 condition was the level of middle-high school. Most of them were retiring and white-collar
124 person. The average age was 66.05 (17-92) years old.

125 The community surveyed in this survey is relatively mature, with an ageing population
126 composition, which is representative of the local community to a certain extent. A total of 653
127 permanent residents were surveyed in 2014, including 337 males and 316 females. The 2018
128 follow-up population was 607, including 311 men and 296 women.

129 The education levels of the test subjects were mainly middle school (and below) level,
130 mostly retired people. The average age of the respondents in 2014 was 66.05 years old (17-92
131 years old), and the average age in 2018 was 67.38 years old (18-91 years old).

132 ***Prevalence of OMDs***

133 In the first survey in 2014, a total of 59 people (9.04%) had OMDs, which contained 12 cases of
134 atrophic glossitis (1.84%), 11 cases of recurrent aphthous ulcer (RAU) (1.68%), 9 cases of
135 Burning Mouth Syndrome (BMS) (1.38%), 8 cases of OLP (1.23%), 8 cases of traumatic ulcer
136 (1.23%), 6 cases of furrowed tongue (0.92%), 3 cases of geographic tongue (0.46%), 1 case of
137 cheilitis (0.15%), 1 case of angular cheilitis (0.15%), and 1 case of leukoplakia (0.15%). The
138 result showed that OMDs were easily local in tongue back, buccal mucosa, labial mucosa and
139 gingival.

140 In 2018, 46 people lost to follow-up (41 normal residents lost to follow-up, 5 mucous
141 membrane patients lost to follow-up, 10 cases of decrease and 9 cases of new). In 2018, 58 cases
142 (9.56%) had mucous membrane disease, as follows: 11 cases of atrophic glossitis (1 case lost,
143 without new), 9 cases of RAU (2 cases lost, without new), 7 cases with furrowed tongue (no loss
144 of follow-up, 1 case of new), 9 cases of OLP (no loss of follow-up, 1 case with DM of new), 7
145 cases of traumatic ulcer (no loss of follow-up, 8 cases of decrease, 7 cases of new), 1 case of
146 geographic tongue (1 case of loss of follow-up, 1 case of reduction). One case each of cheilitis,
147 angular cheilitis and leukoplakia (no loss, no increase, no decrease).

148 ***Distribution condition of various diseases in male and female in 2014***

149 The prevalence rate of female was higher than male's in case of OLP, but there was no statistical
150 significance between male and female in different OMDs ($P > 0.05$), as could be observed in
151 Figure 1.

152 ***Distribution condition of various diseases in different ages of residents in 2014***

153 The cases of RAU and BMS were statistical significance in different ages of residents. The
154 prevalence of RAU in the 15-29 years old group and the 30-39 years old group was significantly
155 higher than that in other high age groups (50-59, 60-69, 70-79) ($P < 0.01$), but there was no

156 significant difference between the two groups ($P>0.05$). BMS was detected more frequently in
157 people over 40 years old, and the prevalence increased with age and was significantly higher in
158 the 70-79 group than in the 40-49 group ($P<0.01$). OLP was detected in the population over 40
159 years old, and there was no significant difference among age groups (Figure 2).

160 *Effect of living habits on OMDs in 2014*

161 Respondents generally were light diet. There were 107 (16.39%) people who persisted smoking
162 for over three years. There were 93 (14.24%) people who persisted drinking (millet wine and
163 beer). The rate of smoking ($p=0.01$) and drink ($p=0.00003$) in OMDs persons were higher
164 compared with no OMDs persons (Figure 3).

165 *Effect of mental state on OMDs in 2014*

166 Our survey showed that 87 people were mental anxiety and 24 people felt higher stress in life
167 ($p=0.0002$). The OMDs person were a higher rate of anxious emotion compared with no OMDs
168 person ($p=0.903$) (Figure 4), and it included 97.5% nice family relationship, 28.1% no friends.
169 36.8% low frequency on interpersonal communication. The 96.2% of respondents didn't have
170 any unfortunate life events in past 12 months.

171 *Analysis of risk factors related to OMDs in 2014*

172 This survey found that there was no significant difference in the prevalence of OMDs between
173 men and women in the population of Baoshan, Shanghai. Meanwhile, it showed that the
174 occurrence of OMDs was positively correlated with the increase of age, and the prevalence of
175 OMDs increased with the increase of age among residents. The incidence of atrophic glossitis,
176 RAU, BMS and OLP were higher.

177 The study also found that smoking, drinking and mental anxiety in OMDs population
178 were significantly higher than the healthy population, but there were no statistical differences.
179 Systemic diseases such as cardiovascular and cerebrovascular hypertension ($P=0.025$), metabolic
180 diseases diabetes ($P=0.028$) were closely related to OMDs. Due to a large number of subjects in
181 the elderly, the investigation group considered that the proportion of dental caries and removable

182 denture in this group was high, and the prevalence of traumatic ulcer would increase
183 correspondingly (table 1).

184 *Analysis of risk factors related to OLP in 2014*

185 OLP was more common in the elderly aged 40-60 years, with more females than males. In this
186 study, OLP mostly occurred in the buccal region. The cause of OLP is complex, and the exact
187 cause is still unknown. The world health organization defines OLP as a potentially malignant
188 disease of the oral mucosa.

189 Currently, there is no specific treatment for OLP in clinical practice, and the condition is
190 often recited, delayed and cured, and the course of the disease is long. OLP has the risk of
191 cancer, which has a vital impact on patients' life and psychology. The results of the general
192 epidemiological investigation showed that there were 8 community residents (1.23%) with OLP,
193 2 males and 6 females. The male to female ratio was 1:3. OLP was significantly associated with
194 age, smoking, and diabetes mellitus ($p < 0.01$) (table 2).

195

196 **Discussion:**

197 In this survey, we discovered that the prevalence rate was 9.04% (2014) - 9.56% (2018). The
198 incidence of atrophic glossitis, RAU, BMS and OLP were higher. The survey of Guoqi Xu (Xu
199 et al., 1981) showed that the prevalence rate was 14.93% on OMDs at 1978 in Shanghai. The
200 Hongkang Cao (Cao et al., 1988) discovered that the prevalence rate of OMDs condition was
201 29.3% on over 60 age elderly in Shanghai. A large-scale epidemiological investigation of
202 Zengtong Zhou (Feng et al., 2015) found that the prevalence of OMDs was 10.8%, which was
203 conducted among 11,054 people in Shanghai in 2012. The work pressure, mental pressure,
204 environmental changes, changes in diet structure, and accelerated the pace of life is bound to
205 lead to increasing OMDs condition.

206 In our study, OMDs were positively correlated with age, and the prevalence increased
207 with age. Therefore, preventive measures of different ages should be taken. Atrophic glossitis
208 occurred mainly in the elderly over 60 years of age in our study, which was consistent with its

209 etiology: chronic anemia, lack of nicotinic acid, Sjogren's syndrome and Candida infection.
210 Among young people aged around 30 and in middle age, there has been a significant increase in
211 the incidence of RAU, with more female patients than male patients. OLP and BMS occurred in
212 older people aged 40-60, and more women than men were ill.

213 In 2014, 8 residents with traumatic ulcers were informed of the treatment at the time of
214 the first transfer. During the 2018 follow-up, all 8 patients dealt with trauma factors and their
215 ulcers had disappeared. It indicated that the community epidemiological survey had diagnostic
216 and popular science functions that contribute to early treatment of residents and reduce cancer
217 risk to the limits of the possibility that ulcers might occur for a long period of time without
218 treatment. It indicated that early prevention and control of mucosal diseases was of great
219 significance. In addition, 7 new cases of traumatic ulcer found in the current investigation were
220 informed of the hazards and treatments one by one, which was considered to be a good
221 demonstration. Many of the interviewees were elderly people with high rates of dental caries and
222 periodontitis. The elderly lacked the awareness to treat dental caries and keep dentures. As a
223 result, the detection rate of traumatic ulcers increased accordingly. In particular, most of the
224 cases occurred in the denture base covering the gums and palate areas. Glossy traumatic ulcers
225 were associated with residual roots and crowns. With the continuous improvement of living
226 standards, the rate of visits to traumatic ulcers gradually increased.

227 Our study showed that OMDs patients who smoke, drink and anxiety were higher than
228 those who were healthy. Plenty of studies have confirmed that tobacco and alcohol are closely
229 related to OMDs and are risk factors for OMDs (Shulman et al., 2004; Dundar & Ilhan Kal,
230 2007; Pentenero et al., 2008; Mohamed & Janakiram, 2014). In past surveys, the incidence of
231 BMS was extremely low and rarely detected. However, the survey found that the incidence of
232 BMS increased, middle-aged and old women in perimenopausal and postmenopausal occurrence,
233 accompanied by obvious changes in psychological and mental state. Might be due to the gradual
234 acceleration of the pace of life in recent years, psychological problems increased year by year.
235 The causes of many diseases, especially chronic diseases, are no longer a simple biological

236 factor, but also include many social, environmental and psychological factors. Alcohol, tobacco,
237 stimulation and mental factors associated with the occurrence and development of oral mucosal
238 diseases should be the focus of primary prevention (O'Sullivan, 2011; Mendes et al., 2012).

239 It is noteworthy that the follow-up observations of community residents after 4 years with
240 OMDs suggested that systemic metabolic diseases such as DM were closely related to OPMDs
241 such as OLP, which is consistent with the results of large-scale oral health epidemiological
242 investigation which we participated in the 2012 in shanghai (Feng et al., 2015). OMDs are vital
243 components of oral diseases, many types and complexities, the prevention and control of OMDs
244 was difficult. At present, the prevention and treatment of OMDs is still the main body of three-
245 level prevention of disease.

246

247 **Conclusion:**

248 Therefore, it is imperative to transfer the prevention nodes of OMDs to primary level and level
249 two prevention. Early prevention and control of mucosal disease is of great significance. It is
250 necessary to understand the prevalence of OMDs among Shanghai residents, to carry out
251 effective intervention activities from the aspects of health education, policy formulation and the
252 creation of supportive environment, to reduce the related risk factors, to promote the health of
253 oral mucosa and to improve the quality of life of the masses.
