Background. Saline-sodic soils are widely distributed in arid and semi-arid regions around the world. High levels of salt and sodium inhibit the growth and development of crops. However, there has been limited reports on both osmotic potential in soil solutions (OP_{ss}) and characteristics of Na^+ and K^+ absorption in rice in saline-sodic soils under various amendments application. **Methods.** A field experiment was conducted between 2009 and 2017 to analyze the influence of amendments addition to saline-sodic soils on rice growth and yield. Rice was grown in the soil with no amendment (CK), with desulfurization gypsum (DG), with sandy soil (SS), with farmyard manure (FM) and with the mixture of above amendments (M). The osmotic potential in soil solution, selective absorption of K^+ over Na^+ (SA), selective transport of K^+ over Na^+ (ST), the distribution of K^+ and Na^+ , and yield components in rice plants were investigated. **Results.** The results indicated that amendments application have positive effects on rice yield. The M treatment was the best among the tested amendments with the highest rice grain yield. M treatment increased the OP_{ss} values significantly to relieve the inhibition of the water uptake by plants.

Additionally, the M treatment significantly enhanced K^+ concentration and impeded Na^+ accumulation in shoots. SA values were reduced while ST values were increased for all amendments. In conclusion, a mixture of desulfurization gypsum, sandy soil and farmyard manure was the best treatment for the improvement of rice growth and yield in the Songnen Plain, northeast China.

21 **Abstract**

22 **Background.** Saline-sodic soils are widely distributed in arid and semi-arid regions around the
23 world. High levels of salt and sodium inhibit the growth and development of crops. However, there
24 has been limited reports on both osmotic potential in soil solutions (OP_{ss}) and characteristics of
25 Na^+ and K^+ absorption in rice in saline-sodic soils under various amendments application.

26 **Methods.** A field experiment was conducted between 2009 and 2017 to analyze the influence of
27 amendments addition to saline-sodic soils on rice growth and yield. Rice was grown in the soil
28 with no amendment (CK), with desulfurization gypsum (DG), with sandy soil (SS), with farmyard
29 manure (FM) and with the mixture of above amendments (M). The osmotic potential in soil
30 solution, selective absorption of K^+ over Na^+ (SA), selective transport of K^+ over Na^+ (ST), the
31 distribution of K^+ and Na^+ , and yield components in rice plants were investigated.

32 **Results.** The results indicated that amendments application have positive effects on rice yield. The
33 M treatment was the best among the tested amendments with the highest rice grain yield. M
34 treatment increased the OP_{ss} values significantly to relieve the inhibition of the water uptake by
35 plants. Additionally, the M treatment significantly enhanced K^+ concentration and impeded Na^+
36 accumulation in shoots. SA values were reduced while ST values were increased for all
37 amendments. In conclusion, a mixture of desulfurization gypsum, sandy soil and farmyard manure
38 was the best treatment for the improvement of rice growth and yield in the Songnen Plain, northeast
39 China.

40 Introduction

41 Soil salinity-sodicity is one of the main impediments for crop productivity and sustainability in arid
42 and semiarid areas (Suarez, 2001; Qadir et al., 2006). Saline-sodic soils comprise approximately 3.67×10^7
43 ha, and Songnen Plain is one of the major saline-sodic areas in China (Yao et al., 2008; Yang et al., 2016).
44 pH stress and Na^+ toxicity are the main causes of the degradation in saline-sodic soils (Gharaibeh et al.,
45 2010). Efforts have been made to ameliorate saline-sodic soils including desulfurization gypsum, farmyard
46 manure, sand, hydraulic engineering and phytoremediation (Qadir et al., 2007; Wang et al., 2012; Ahmad
47 et al., 2013).

48 Desulfurization gypsum provides a sources of Ca^{2+} to replace exchangeable Na^+ , thereby improving
49 the physical condition of the soil and increasing water infiltration (Oster, 1982; Wang et al., 2013; Wang
50 & Yang, 2018). Manure application improves soil structure and alleviates soil sodicity (Yu et al., 2010).
51 Sanding to saline-sodic soils changes soil compactness and reduces salt content (Wang et al., 2010). These
52 amendments showed various improvements of saline-sodic soil properties in practice.

53 Crops respond to salinity and sodicity in two phases: (1) a continuous osmotic phase that occurs when
54 the potential energy of the saline-sodic soil solution is lowered by its osmotic pressure, thus inhibiting the
55 water uptake of plants; and (2) a slower ionic phase due to ion toxicity or ion imbalance as plants accumulate
56 salt ions over a period of time (Munns & Tester, 2008). Most amendment studies focused on soil
57 physiochemical properties (Chi et al., 2012; Zhao et al., 2018) rather than on the osmotic potential in the
58 soil solution and the selective absorption of ions by plants, although they have important effects on crop

59 biomass (Wang et al., 2009).

60 Rice showed moderate sensitivity to salinity and sodicity (Maas & Hoffman, 1977). Kelly &
61 Rengasamy (2006) showed that osmotic stress is one of the major factors in reducing crop yield. The
62 decreasing the osmotic potential of the soil solution was inhibitory to the water uptake of plant roots (Duarte
63 & De Souza, 2016). The survival of rice plants under saline-sodic conditions is correlated with Na^+ and K^+
64 accumulations in plant tissues (Song & Fujiyama, 1996). Yamanouchi et al. (1987) found that Na^+
65 concentrations in shoots are inversely correlated with the relative plant growth and yield. The susceptibility
66 of rice plants to salinity and sodicity stress is due to the limited ability to restrict Na^+ transportation to shoots
67 (Matsushita & Matoh, 1991). This Na^+ restricts K^+ uptake and K^+ is an essential macronutrient for the
68 growth of plants and cannot be substituted by Na^+ (Bhandal & Malik, 1988). The ability of plants to keep
69 a high cytoplasmic K^+/Na^+ ratio is one of the most important mechanisms of salt tolerance (Maathuis &
70 Amtmann, 1999).

71 In this study, we measured the osmotic potential in the soil solution, characterized K^+ and Na^+
72 absorption of rice, K^+ and Na^+ concentrations in shoots and roots, selective absorption/transport for K^+ over
73 Na^+ , distribution of K^+ , Na^+ in rice organs, and yield of rice under various soil treatments, including
74 chemical treatment (desulfurization gypsum, DG), physical treatment (sandy soil, SS) and organic treatment
75 (farm manure, FM) as well as mixed treatment (M) in saline-sodic soil for planting rice in field. We
76 hypothesized that (1) amendments would increase the osmotic potential in soil solutions; (2) amendments
77 would alter the ion selective absorption and selective transport in saline-sodic soils and (3) the grain yield
78 of rice would be highest by M application according to the synergy among treatments when they applied
79 together in the Songnen Plain, northeast China.

80 **Materials & Methods**

81 **Location description**

82 The study was conducted from 2009 to 2017 at Da'an Sodic Land Experiment Station (45°35'58"-
83 45°36'28"N, 123°50'27"-123°51'31"E, 132.1), operated by the Chinese Academy of Sciences. The climate
84 of this region is semi-humid to semi-arid continental monsoon. The annual mean air temperature is 4.7°C,
85 and the mean annual precipitation of this area is approximately 400-500 mm, and 80% or more of the

86 precipitation occurs between May and September.

87 The soil at this study site is classified as clay loam texture with montmorillonite as a dominant mineral.
88 The soil prior to the start of the experiment represents a typically severe saline-sodic soil with pH (1: 5
89 H₂O) of 10.47, electrical conductivity (EC) (1: 5 H₂O) of 2.36 mS cm⁻¹, soil organic C (SOC) of 2.80 g kg⁻¹
90 and exchangeable sodium percentage at 79.7% in the top 20-cm soil layer, which is considered to be the
91 effective rooting zone. The main soluble cation was Na⁺, while the anions were HCO₃⁻ and CO₃²⁻. Based
92 on the World Reference Base for Soil Resources (IUSS Working Group WRB, 2007), the main soil type
93 was classified as solonetz.

94 **Field design and treatments**

95 The experiment was arranged in a random block design with three replicates of 20 m² for each plot.
96 There were five treatments: (1) CK, without amendment application; (2) DG, amended with desulfurization
97 gypsum (containing 93% CaSO₄·2H₂O) at 3 kg m⁻²; (3) SS, amended with sandy soil at 6 kg m⁻²; (4) FM,
98 amended with 6 kg m⁻² farmyard manure (5) M, amended with the mixture of desulfurization gypsum,
99 sandy soil and farmyard manure, the amounts of which are equal to those in the DG, SS and FM treatments.
100 Some essential properties of the amendments used in the present study are presented in Table 1 (Luo et al.,
101 2018). Plastic cloth buried between plots to a depth of 1 m soil separated plots to prevent disturbance of
102 lateral movement of amendments, water and salt.

103 The soil amendments were only applied once before the start of this experiment in the late autumn,
104 2009. The soil amendments were mixed with the 0-20 cm soil layer by rotary cultivator and then irrigation
105 was carried out after 24 h. The CK was also treated by the same method except for the amendment.
106 Agronomic and fertilizer management practices for rice cultivation were the same in all plots and were in
107 accordance with the prevalent system of agriculture in this area. Chemical fertilizers were broadcast over
108 the soil annually at rates of 207 kg N ha⁻¹ (as urea containing 46% N), 78 kg P ha⁻¹ (as calcium super
109 phosphate containing 12% P₂O₅) and 60 kg K ha⁻¹ (as potassium sulfate containing 45% K₂O). The soil was
110 then plowed to mix the fertilizers into the subsoil.

111 The local rice cultivar (G19) was planted after wet plowing and sinking between May 20 to the end of
112 May every year for the experiment. Rice seed was sown on normal soil in a greenhouse in early April for

113 nursing, and the 40-day seedlings were transplanted into the plots with a fixed planting spacing of 30×16.7
114 cm. Planting space of 30×16.7 cm is a common practice to avoid lodging, and cultivation of 3-5 seedlings
115 per hill is recommended in saline-sodic soil in the Songnen plain (Wang et al, 2010). The depth of 3-7 cm
116 standing water was maintained in the paddy through flood irrigation and runoff drainage during the growth
117 stages of rice. The soils were all drained in the middle of September for harvest.

118 **Measurements**

119 K^+ and Na^+ concentrations in rice plant were measured by sampling three hills excluding the border
120 hills from each plot on 20 days before harvesting. The selected rice hills were observed to be representative
121 of the plot. The rice plants were separated into roots, leaves, sheaths and panicles. The roots were
122 thoroughly washed with water to remove the soil particles. Clean roots were used for estimating Na^+ and
123 K^+ concentrations. Plant samples were dried for 48h at $80^\circ C$ in an air-forced oven. Dried materials were
124 finely grounded using a ball mill. They were then digested using an acid mixture [sulphuric acid: perchloric
125 acid (H_2SO_4 : $HClO_4=4:1$)] (Mori et al., 2011). K^+ and Na^+ concentrations were determined using an atomic
126 absorption spectrometer (GGX-900). K^+ and Na^+ concentrations in the shoot were calculated from K^+ and
127 Na^+ concentrations and dry weights of grains, leaves and sheaths, K^+ and Na^+ concentrations in the whole
128 plant were calculated from K^+ and Na^+ concentrations and dry weights of grains, leaves, sheaths and roots.

129 At harvest in October, the following growth and yield data were determined in 2010, 2012, 2015 and
130 2017: plant height, panicle length, number of grains per panicle, 1000-grain weight and grain yield (Zeng
131 et al., 2000).

132 To analyze the soil properties as affected by different amendments, soil sampling was performed after
133 harvest of the rice in the November, 2017. All soil samples, obtained from each plot at six depths of 0-10
134 cm, 10-20 cm, 20-40 cm, 40-60 cm, 60-80 cm and 80-100 cm, . were dried at $105^\circ C$ for 24 h and passed
135 through a 2-mm diameter sieve. Soil samples were analyzed for electric conductivity (EC in $dS\ m^{-1}$), soluble
136 K^+ , Na^+ and Ca^{2+} using 1: 5 soil to water extracts as described by Sumner (1993).

137 The EC of 1: 5 soil to water extracts ($EC_{1:5}$) was determined by DDS-307 conductivity meter (Shanghai
138 Precision Scientific Instrument Co., Ltd., China), the concentrations in $mmol/L$ of K^+ , Na^+ were determined
139 using flame photometry (FP-6410) and the concentration of Ca^{2+} was measured by EDTA titration (Jackson,

140 1956).

141 The osmotic potential can serve as a good index for evaluating plant response to saline-sodic stress
142 (De Souza et al., 2012). In this experiment, we regard the 1: 5 soil to water extracts as soil solution, and the
143 osmotic potential in the soil solution (OP_{ss}) was calculated as follows:

$$144 \quad OP_{ss} = (-0.36) \times 10EC \text{ (Bohn et al., 2002)}$$

145 **SA and ST Calculation**

146 Selective absorption of K⁺ over Na⁺ (SA) represents the net capacity of a plant to absorb K⁺ relative
147 to Na⁺ from the shallow soil (0-40 cm); Selective transport of K⁺ over Na⁺ (ST) reflects the net capacity of
148 a plant to favour transport of K⁺ over Na⁺ from the root to shoot (Wang et al., 2004). In this study, SA and
149 ST values were calculated according to the following formula (Wang et al., 2002; Wang et al., 2004) using
150 data obtained from the experiments described earlier:

$$151 \quad SA = (K/Na \text{ in root dry weight}) / (\text{soil } K/Na \text{ at } 0\text{-}40 \text{ cm depth})$$

$$152 \quad ST = (K/Na \text{ in shoot dry weight}) / (K/Na \text{ in root dry weight})$$

153 **Statistical analysis**

154 Data were statistically evaluated by analysis of variance (ANOVA). The differences between mean
155 values were evaluated by the Duncan test. All analyses were done with the SPSS 20.0 software (New York,
156 USA). A $P=0.05$ value was used to designate statistically significant results.

157 **Results**

158 **Effect of amendments application on osmotic potential in soil solution**

159 The osmotic potential in the soil solution (OP_{ss}) was increased by amendments application compared
160 to the control. The amplitude of variation of OP_{ss} was from -4.39 bars in the 80-100 cm soil layer under CK
161 treatment to -1.04 bars in the 10-20 cm soil layer under M treatment. In the 0-40 cm soil layer, amendments
162 application generally increased the OP_{ss} values in the following order: M>DG>SS>FM>CK (Figure 1). In
163 the 0-10 cm soil layer, the M, DG, SS and FM treatment increased the OP_{ss} by 53.8%, 40.1%, 29.1% and
164 12.2% compared to the CK treatment, respectively. In the same soil layer, the highest OP_{ss} was observed
165 for M, which means that the ability to reduce the salt concentration of soil solution is strongest, followed
166 by DG.

167 **Effect of amendments application on Na⁺ and K⁺ concentrations in rice shoots and**
168 **roots**

169 The Na⁺ concentration in shoots of rice plants varied with different amendments applied in the saline-
170 sodic soil (Figure 2A). Rice shoots of plants in M treatment showed the lowest Na⁺ concentration of 0.91
171 mg/g dry weight, and the Na⁺ concentrations in FM, CK, SS and DG treatments were 4.4%, 7.7%, 8.8%
172 and 11.0% higher than that in M treatment, respectively. The difference in Na⁺ concentration between DG
173 and M treatments was significant. The mean root Na⁺ concentration was highest in the CK treatment, and
174 0.8%, 7.1%, 9.2% and 15.1% lower in M, SS, FM and DG treatments, respectively. However, the
175 differences on Na⁺ concentration in rice root among amendment treatment and CK were non-significant.
176 among amendments treatment and CK were non-significant (Figure 2B). Amendments application
177 significantly enhanced K⁺ concentration in rice shoots compared to the control treatment, with the highest
178 K⁺ concentration found for DG (Figure 2C). The K⁺ concentration in rice roots with M, SS, FM treatments
179 were lower than that with the control treatment. The lowest K⁺ concentration was observed for FM, which
180 was 16.8% lower than that of CK (Figure 2D).

181 **Selective absorption and transport of K⁺ over Na⁺ in rice plant**

182 Compared to the CK treatment, the M treatment significantly decreased the SA value of the rice by
183 74.8% (Figure 3A). However, the M treatment significantly increased the ST value of the rice compared to
184 the CK treatment, which was 1.5 times more than the ST value of the CK treatment (Figure 3B).
185 Amendment application hindered the uptake of K⁺ over Na⁺ from soil to root (SA) compared with CK
186 (Figure 3A), which is probably a consequence of rice physiological adjustment. Amendment application
187 enhanced the uptake of K⁺ over Na⁺ from root to shoot (ST) compared with CK (Figure 3B). This was
188 attributed to strong selective transport of K⁺ over Na⁺ under amendment application.

189 The mean Na⁺ concentration in the soil extracts decreased from a maximum (6.68 mmol_e/L) in the CK
190 treatment to 3.16, 4.35, 5.11 and 6.60 mmol_e/L with M, DG, SS and FM treatments, respectively. The
191 differences among M, DG and CK were significant (Figure 4A). Amendment application slightly enhanced
192 the K⁺ concentration in the soil extracts compared to CK (Figure 4B). The Ca²⁺ concentration in the soil
193 extracts were higher for treatments with amendments than the one without, and differences among the 4

194 different amendments were not significant (Figure 4C).

195 **Characteristics of distribution of Na⁺ and K⁺ in rice with different amendments** 196 **application**

197 There were little differences in Na⁺ concentration in the whole rice plants among different treatments
198 in the saline-sodic soils in this experiment (Figure 5A). K⁺ concentration in the whole plant was
199 significantly enhanced after amendment application, but the differences between the 4 treatments with
200 amendments were non-significant (Figure 5B). Na⁺ absorbed by the whole plant was almost the same with
201 and without amendments, which was different from the observations on rice organs (Figure 5A and Table
202 2). The Na⁺ concentrations in rice roots and grains both decreased when applying amendments in the saline-
203 sodic soils; which were contrary to the rise of K⁺ concentrations in sheaths and leaves (Table 2). Compared
204 to the control treatment, DG, SS, FM and M treatments increased the K⁺ concentrations in rice sheaths by
205 57.2%, 54.9%, 44.1% and 25.5%, respectively.

206 For the distribution of ions in rice organs, there was a higher proportion of the total K⁺ in leaves. More
207 Na⁺ was found in roots. The order of accumulation of Na⁺ in various organs was
208 roots>leaves>sheaths>grains (Table 2). The order is imposed by the fact that the root system retains more
209 Na⁺ and prevents Na⁺ from being transported to the aboveground organs in saline-sodic soils, resulting in
210 higher K⁺ proportion in leaves, sheaths and grains. This was also illustrated as being beneficial to normal
211 metabolic activity (Borsani, 2001; Ahmad & Jabeen, 2005).

212 **Relationship between OP_{SS}, selective absorption and yield of rice**

213 The grain yield of the four years of 2010, 2012, 2015 and 2017 were taken as representative of the
214 trend of rice yield from 2009 to 2017 (Figure 6). In terms of grain yield, the M was the best treatment, next
215 is the DG treatment. The grain yield of rice with amendments application were significantly higher than
216 without amendments application except in 2015.

217 Amendment treatments significantly enhanced the grain yield of rice compared to the control in 2017
218 (Table 3). The differences, however, among different amendments were not significant at $P<0.05$. Soil
219 amendment application generally increased the 1000-grain weight in the following order:
220 FM>M>DG>SS>CK (Table 3). Additionally, the FM and M treatments significantly increased the 1000-

221 grain weight to 1.16 and 1.13 times more than the CK treatment, respectively (Table 3). Compared to the
222 CK treatment, the SS treatment considerably enhanced the number of grains per panicle (Table 3). There
223 was no significant difference on rice height and panicle length between various treatments (Table 3).

224 Significant positive correlations were found between OP_{ss} in the 0-20 cm soil layer and the 1000-grain
225 weight ($R^2=0.992$, $P<0.001$, Table 4). Significant negative correlations were found between SA and rice
226 grain yield ($R^2=0.925$, $P<0.05$, Table 4) and between SA and 1000-grain weight of rice ($R^2=0.884$, $P=0.047$,
227 Table 4). There was no significant correlation between either SA or ST and other growth parameters and
228 yield of rice (Table 4).

229 Discussion

230 Characteristics of Na^+ and K^+ absorption in rice

231 Compared with the CK treatment, the selectivity absorption of K^+ over Na^+ (SA) decreased
232 significantly with the M application in this study. When the M applied, osmotic stress and Na^+ toxicity were
233 significantly decreased leading to better plant growth in saline-sodic soils (Swarup, 1982; Yuncai et al.,
234 2005; Luo et al., 2018; Shi et al., 2019). Similar to our results, previous studies have shown that plants
235 accumulate excessive Na^+ in their shoots under stress caused by high salinity-sodicity (Roy & Mishra,
236 2014), and Na^+ concentration in shoots increased significantly with a surge in soil salinity-sodicity (Syed
237 & Abdur, 2017).

238 Adding amendments reduces the salinity-sodicity stress of plants growing in the amended soil
239 (Chaganti & Crohn, 2015). Therefore, the rice planted in the CK plot was under a higher external salinity-
240 sodicity stress. As a result, the SA value of rice plants with CK was higher than those with amendments
241 application and maintained a high cytosolic K^+/Na^+ ratio. This is thought to be one of the most important
242 mechanisms of salt tolerance exhibited by plants (Gorham, 1990; Dubcovsky et al., 1996; Munns & James,
243 2008; Munns et al., 2010).

244 Effects of Ca^{2+} on SA and ST values

245 The competition of K^+ and Na^+ entry into plants can result in significant adverse effects on plants'
246 growth, where concentrations of Na^+ often exceed those of K^+ (Tester & Davenport, 2003). Therefore, the
247 maintenance of a high K^+/Na^+ ratios in plants is essential (Maathuis & Amtmann, 1999). Amendments of

248 Ca^{2+} promoted K^+ over Na^+ absorption, resulting in the enhancement of selectivity absorption of K^+ over
249 Na^+ (Alama et al., 2002). Ca^{2+} can replace Na^+ in plants which restores cell wall stability and plasma
250 membrane integrity (Zhang et al., 2010; Wu & Wang, 2012). Although alleviation of Na^+ toxicity by
251 supplemental Ca^{2+} was confirmed, the responses varied with different plant species. Under similar saline-
252 sodic conditions, amendments of Ca^{2+} were found to obviously increased K^+/Na^+ selectivity of both roots
253 and shoots (SA and ST values) in *Medicago sativa* (Al-Khateeb, 2006) and *Cornus sericea* (Renault &
254 Affifi, 2009). This is contrast to Wang et al. (2007) who reported that amendments of Ca^{2+} had no influence
255 on SA and ST values of *Suaeda maritima*. In addition, the responses of Ca^{2+} to Na^+ also varied with osmotic
256 potential in soil solution in the same plant species. In rice, Ca^{2+} did not have significant effects on selective
257 absorption and selective transport of K^+ over Na^+ of plants when subjected to low osmotic potential in soil
258 solution (Yeo & Flowers, 2010). This is consistent with the results obtained in the present study: there were
259 not significant differences among CK, DG, SS and FM treatment on SA and ST values (Figure 3). In
260 contrast, M application significantly decreased roots Na^+ absorption and increased shoots K^+ accumulation
261 in rice. It is proposed that the presence of Ca^{2+} could enhance K^+/Na^+ selectivity and regulate ion
262 homeostasis in rice under low saline-sidicity condition.

263 In rice, a minority of the ions reaching the shoots of plant are the consequence of leakage along the
264 transpirational bypass flow to the xylem and Ca^{2+} application can reduce the bypass flow of rice (Faiyue et
265 al., 2010; Anil et al., 2005). This reduction in the bypass flow is positively related with the concomitant
266 reduction in the shoot Na^+ uptake (Anil et al. 2005). In addition, a majority of the ions reaching the shoots
267 of rice should be transported via the symplast pathway. Therefore, Ca^{2+} plays important role in regulating
268 apoplast and symplast pathways involved in Na^+ transport.

269 **Yield of rice**

270 Transient salinity affects the plants' absorption of available water, which results in a reduction in plant
271 yield (Rengasamy, 2010a, 2010b). However, application of amendments to saline-sodic soils can alleviate
272 the salinity-sodicity stress on plants (Irshad et al., 2002). Amendments application in our study enhanced
273 the OP_{ss} values, and then decreased osmotic pressure of the soil solution. This ultimately increased the plant
274 growth and yield of rice in the saline-sodic soils. Applying a small amount of calcium thus was shown to

275 enhance the plants' salt tolerance (Cramer, 1992).

276 The grain yield of rice was higher with amendment application compared to that with CK treatment.
277 There were significant negative correlations between SA and rice grain yield ($R^2=0.925$, $P<0.05$, Table 4),
278 a possible explanation for this result is that the low SA values of plant was partly ascribed to its relative
279 sensitivity to root which increased the Na^+ accumulation in root and therefore decreased the SA values
280 (Leland & Eugene, 1999; Ren et al., 2005; Tsialtas & Maslaris, 2009).

281 DG, SS and FM application are known to improve the root environment and increase rice yield
282 (Abrishamkesh et al., 2015). In this study, we found that the mixture of DG, SS and FM application reduced
283 the absorption of Na^+ in rice shoots significantly and led to the highest rice grain yields, which may be due
284 to the synergistic effect of these three amendments. However, the each amendment contribution to the rice
285 yield needs to be quantified in future studies.

286 **Conclusions**

287 In this field experiment, the amendments application significantly increased the yield of rice. In
288 particularly, the M treatment was the best among the tested amendment treatments with the highest rice
289 grain yield in the saline-sodic soils although the differences between amendments treatment were not
290 significant. Relative to the CK treatment, the FM and M treatments significantly enhanced the 1000-grain
291 weight and the SS treatment significantly improved the number of grains per panicle. The amendments
292 treatment increased the OP_{ss} significantly, thus relieving the inhibition of water uptake by plants. In
293 addition, a positive effect of amendments application on reducing Na^+ accumulation and increasing the
294 uptake of K^+ of rice shoot was observed. Amendments application increased ST values and decreased SA
295 values. Moreover, there existed an ion regionalization distribution in rice plant; there was a higher K^+
296 proportion in leaves and a higher Na^+ proportion in roots. Collectively, the mixture of desulfurization
297 gypsum, sandy soil and farmyard manure provided excellent results for increasing the yield of rice in the
298 saline-sodic soils in the Songnen Plain, northeast China.

299 **Acknowledgements**

300 We thank Da'an Sodic Land Experiment Station of China for providing experimental plot.

FM	94.2±1.1a	14.3±0.3a	68.9±8.4ab	22.4±0.7a	5790±209.9a
M	92.5±2.6a	14.3±0.3a	78.2±4.6ab	21.9±0.9a	6030±209.9a

2 Note: mean value and its standard error (SE) are reported. Different letters denote means that are significantly
3 different from each other ($P<0.05$). CK, control, without amendments application; DG, desulfurization gypsum;
4 SS, sandy soil; FM, farmyard manure; M, mixture of desulfurization gypsum, sandy soil and farmyard manure.

Table 4(on next page)

Correlation coefficients among OP, SA, ST values and different growth and yield of rice in 2017.

Note: * and ** denote correlation at the 0.05 and 0.01 levels of significance, respectively.

1 Table 4. Correlation coefficients among OP, SA, ST values and different growth and yield of rice in 2017.

	OP _{SS} (bars)	SA (selective absorption)	ST value (selective transport)	Height (cm)	Panicle length (cm)	Number of grains per panicle	1000-grain weight (g)
SA (selective absorption)	-0.857						
ST (selective transport)	0.628	-0.879*					
Height (cm)	0.695	-0.589	0.278				
Panicle length (cm)	-0.146	-0.205	0.391	-0.62			
Number of grains per panicle	0.276	-0.492	0.319	-0.08	0.727		
1000-grain weight (g)	0.992**	-0.884*	0.671	0.619	-0.024	0.375	
Grain yield (kg/ha)	0.789	-0.925*	0.821	0.303	0.477	0.714	0.855

2 Note: * and ** denote correlation at the 0.05 and 0.01 levels of significance, respectively.
