Nut-cracking is often cited as one of the most complex behaviours observed in wild chimpanzees. However, the cognitive mechanisms behind its acquisition are still debated. The current null hypothesis is that the form of nut-cracking behaviour relies on variants of social learning, with some researchers arguing, more precisely, that copying variants of social learning mechanisms are necessary. However, to date, very few experiments have directly investigated the potentially sufficient role of individual learning in explaining the behavioural form of nut-cracking. Despite this, the available data provides some evidence for the spontaneous acquisition of nut-cracking by chimpanzees; later group acquisition was then found to be at least facilitated by (unspecified) variants of social learning. The latter findings in line with both suggested hypotheses, i.e., that copying social learning is required and that other (non-copying) social learning mechanisms are at play. Here we present the first study which focused (initially) on the role of individual learning for the acquisition of the nut-cracking behavioural form in chimpanzees. We tested task-naïve chimpanzees (N=13) with an extended baseline condition to examine whether the behaviour would emerge spontaneously. After the baseline condition (which was unsuccessful), we tested for the role of social learning by providing social information in a step-wise fashion, culminating in a full action demonstration of nut-cracking by a human demonstrator (this last condition made it possible for the observers to copy all actions underlying the behaviour). Despite the opportunities to individually and/or socially learn nut-cracking, none of the chimpanzees tested here cracked nuts using tools in any of the conditions in our study. We conclude that this failure was the product of interplay of factors, including behavioural conservatism and the existence of a potential sensitive learning period for nut-cracking in chimpanzees. The possibility remains that nut-cracking

is a behaviour that chimpanzees can individually learn. However, this behaviour might only be acquired when chimpanzees are still inside their sensitive learning period, also when ecological and developmental conditions allow for it. The possibility also remains that nut-cracking is an example of a culture dependent trait in non-human great apes. Recommendations for future research projects to address this question are considered.

29 Abstract

30 Nut-cracking is often cited as one of the most complex behaviours observed in wild
31 chimpanzees. However, the cognitive mechanisms behind its acquisition are still debated. The
32 current null hypothesis is that the form of nut-cracking behaviour relies on variants of social
33 learning, with some researchers arguing, more precisely, that copying variants of social learning
34 mechanisms are necessary. However, to date, very few experiments have directly investigated
35 the potentially sufficient role of individual learning in explaining the behavioural form of nut-
36 cracking. Despite this, the available data provides some evidence for the spontaneous acquisition
37 of nut-cracking by chimpanzees; later group acquisition was then found to be at least facilitated
38 by (unspecified) variants of social learning. The latter findings in line with both suggested
39 hypotheses, i.e., that copying social learning is required and that other (non-copying) social
40 learning mechanisms are at play. Here we present the first study which focused (initially) on the
41 role of individual learning for the acquisition of the nut-cracking behavioural form in
42 chimpanzees. We tested task-naïve chimpanzees (N=13) with an extended baseline condition to
43 examine whether the behaviour would emerge spontaneously. After the baseline condition
44 (which was unsuccessful), we tested for the role of social learning by providing social
45 information in a step-wise fashion, culminating in a full action demonstration of nut-cracking by
46 a human demonstrator (this last condition made it possible for the observers to copy all actions
47 underlying the behaviour). Despite the opportunities to individually and/or socially learn nut-
48 cracking, none of the chimpanzees tested here cracked nuts using tools in any of the conditions
49 in our study. We conclude that this failure was the product of interplay of factors, including
50 behavioural conservatism and the existence of a potential sensitive learning period for nut-
51 cracking in chimpanzees. The possibility remains that nut-cracking is a behaviour that
52 chimpanzees can individually learn. However, this behaviour might only be acquired when

53 chimpanzees are still inside their sensitive learning period, also when ecological and
54 developmental conditions allow for it. The possibility remains that nut-cracking is an example
55 of a culture dependent trait in non-human great apes. Recommendations for future research
56 projects to address this question are considered.

57

58 Introduction

59 Humans have created a unique niche within the animal kingdom, one that (most likely)
60 relies on an ability to transfer knowledge between and within generations, allowing our species
61 to inhabit almost every environment on the planet. However, modern industrialised human
62 society is so far removed from that of our ancestors, that it is difficult to understand how our
63 cultural ability – or our cultural niche (Odling-Smee, Laland, & Feldman, 2003) – evolved.
64 Therefore, the closest extant relatives of the *hominin* clade, non-human great apes (hereafter:
65 apes), are often used as a phylogenetic proxy to help shed light on our own evolution.

66 Modern human culture may be unique in the animal kingdom (Tomasello, 1998) – at
67 least in the technological domain (Tennie, Caldwell, & Dean, 2018). Thus, to allow for the study
68 of culture *across* species, a more minimal (or soft) definition of culture is required. Here we
69 follow the terminology suggested recently by Neadle, Allritz and Tennie (2017), in which a
70 cultural trait is any behaviour that is at least influenced (including merely its frequency being
71 facilitated or catalysed; Tennie, Call, & Tomasello, 2010) by social learning. Within this
72 definition of culture, the social learning mechanisms at play can be any of the many proposed
73 variants (for an overview, see Whiten, Horner, Litchfield, & Marshall-Pescini, 2004). This
74 minimal definition of culture allows for the identification of cultures that involve a range of
75 social learning variants, including ones that rely on the copying of behaviour directly (often
76 called imitation, see, e.g., Whiten & Ham, 1992). Crucially, the minimal definition of culture
77 also encompasses examples of behavioural forms that can emerge without requiring social
78 learning. Instead, behaviours that *rely* on (i.e., cannot occur in the absence of) copying variants
79 of social learning are ‘culture dependent traits’ (henceforth CDTs; see Reindl, Apperly, Beck, &
80 Tennie, 2017; Tennie, Caldwell, & Dean, 2018). Some animal cultures may be culture dependent
81 (e.g., whale song is a candidate CDT; Tennie et al., 2018), but whether any animal tool use

82 qualifies as CDT is a matter of considerable debate (Galef, 1992; Kendal, 2008; Tennie, Call, &
83 Tomasello, 2009). In the human case, technology has often evolved to the point that no naïve
84 individual could reinnovate the behaviour on their own within their lifetime (Galef, 1992;
85 Tomasello, Kruger, & Ratner, 1993), making many modern human traits CDTs and indeed
86 examples of cumulative culture (Boyd & Richerson, 1996) .

87 Amongst non-human animals (hereafter: animals), chimpanzees (*Pan troglodytes*) are,
88 for now, the ‘most cultural’ species – at least in terms of (known) numbers of cultural traits
89 (Whiten et al., 1999) – where a mere increase in sheer number of cultural traits is known as
90 accumulation (Dean, Vale, Laland, Flynn, & Kendal, 2014). However, accumulation (numbers of
91 traits) should not be confused with *cumulation*, i.e. the cultural change of the traits themselves
92 along transmission pertaining to cumulative culture (Dean et al., 2014). Only the latter is the
93 result of the ‘ratchet effect’ (Tomasello et al., 1993), which underlies cumulative culture (Boyd
94 & Richerson, 1996) – and is responsible for the special product of cumulative culture: CDTs
95 (Reindl et al., 2017). Therefore, whilst chimpanzees’ number of cultural traits is impressive, for
96 those concerned with human cultural evolution, the presence or absence of CDTs in chimpanzees
97 is of particular interest.

98 Regarding chimpanzee culture, nut-cracking is considered one of the most complex
99 behaviours expressed by any wild apes. Complexity can refer to the number of parts within a
100 final artefact/behaviour (techno-units; Oswalt, 1976), the goals and sub goals of an action (Read
101 & Andersson, 2019), the manual dexterity of an action (Foucart et al., 2005) and the number of
102 “rules” necessary to describe the behaviour (Sirianni, Mundry, & Boesch, 2015), amongst other
103 metrics (see Vaesen & Houkes, 2017 for further discussion of complexity). Nut-cracking
104 requires a high level of dexterity (Foucart et al., 2005) and involves several tools in various steps

105 that need to be followed in a specific sequential order to produce the desired effect (Biro et al.,
106 2003; Boesch, Bombjaková, Meier, & Mundry, 2019; Inoue-Nakamura & Matsuzawa, 1997;
107 Read & Andersson, 2019); thus, it can be considered a complex behavioural form. Furthermore,
108 nut-cracking is rare across wild communities, (so far) only being documented in two
109 geographically separate populations: two communities in West Africa (Bossou, Guinea and Tai
110 Forest, Côte d'Ivoire Whiten et al., 2001) and one in Ebo Forest, Cameroon (Morgan & Abwe,
111 2006; although note that these data are based on indirect evidence and should be treated with
112 some degree of caution).

113 The number of steps alongside with the manual dexterity and use of multiple objects
114 required for this behaviour suggests that nut-cracking is most likely a complex behaviour for
115 chimpanzees. The basic behavioural form of nut-cracking consists of the following four
116 sequential steps, though note that other steps might occur:

- 117 1. Place nut on anvil
- 118 2. Pick up hammer (unless already picked up)
- 119 3. Lift hammer up
- 120 4. Drop/push the hammer onto nut (all may be repeated).

121 Perhaps due to this apparent complexity, nut-cracking is often assumed to be culturally
122 transmitted (Boesch & Boesch-Achermann, 2000; Lycett, Collard, & McGrew, 2007, 2010),
123 with some researchers arguing that action copying (or imitation) must be the mechanism
124 responsible for its acquisition. For example, Boesch (1996) claims that chimpanzees learn how to
125 crack nuts “by individual and social learning, *including imitation*” (Boesch, 1996, p. 418,
126 emphasis added), Biro et al (2003, p. 220) further argue that when nut-cracking “infant
127 chimpanzees are driven not by a motivation for food but to produce a *copy of the mother's*

128 *actions*” [emphasis added]. More generally, others agree, claiming that nut-cracking (alongside
129 other chimpanzee traits) are difficult to explain “by social learning processes simpler than
130 imitation” (Whiten et al., 1999, p. 685). More recently, similar claims have been made that
131 chimpanzees rely on mother to infant “*teaching*” to acquire the skills required to crack nuts at a
132 rate consistent with that of others within their community (Boesch et al., 2019). Some have
133 further argued that young wild chimpanzees engage with this process during a so-called
134 ‘sensitive learning period’ between the ages of approx. 3.5 years and 10 years (Inoue-Nakamura
135 & Matsuzawa, 1997; Matsuzawa, 1994; Biro et al., 2003).

136 However, other research has suggested that migratory primates, outside the estimated
137 sensitive learning period, can still engage with and adopt behaviours – perhaps in keeping with
138 their new groups. Most relevant here, Luncz, Mundry and Boesch (2012) describe how migrant
139 female chimpanzees adapt their hammer choice during nut-cracking to conform to that of their
140 new group. The migrating females were beyond the age of sexual maturity, and so outside their
141 sensitive learning period. The fact that these individuals can modify their behaviour in this way,
142 suggests that the possibility remains for individuals outside of the sensitive learning period to
143 adopt the full behavioural form. This said, these findings are not evidence of the behavioural
144 form of nut-cracking emerging for the first time, instead are evidence of behaviours being
145 adapted and therefore whilst interesting might not represent a strong argument against the notion
146 of a sensitive learning period.

147 In conclusion, the behaviours underpinning nut-cracking have been argued to require
148 social learning (in particular action copying and/or unspecified variants of teaching). Therefore,
149 it has been assumed that nut-cracking is outside of naïve chimpanzees’ individual learning
150 abilities, which would make nut-cracking a CDT (sensu Reindl et al., 2017). This is a clear claim

151 that can be tested. If nut-cracking requires social learning (if it is indeed a CDT), it should re-
152 appear when a naïve chimpanzee has access to a model nut cracker to observe. This would
153 provide evidence for the view that social learning is required for nut-cracking to occur. However,
154 the absence of data should not be considered as evidence itself; accordingly, the lack of evidence
155 for nut-cracking even at the end of this study should only be considered as an indication that it
156 might not be a CDT rather than concrete evidence for it, such a result would need replicating in
157 another population before confident assumptions can be made from the data. Indeed, it is
158 possible that environmental, social or individual factors might influence the likelihood of
159 expression (*sensu* Tennie et al., 2009). However, if nut-cracking does occur in a baseline
160 condition in this naïve population, this *would* constitute evidence that naïve chimpanzees have
161 the capacity to reinnovate nut-cracking in the absence of social learning (i.e. it is within the
162 species' ZLS).

163 In one formulation, the Zone of Latent Solutions (ZLS) hypothesis (Tennie et al., 2009)
164 posits that all non-human great ape 'cultural' behaviours can be reinnovated (defined by Bandini
165 & Tennie, 2017) by naïve apes. This specific case has been termed as the 'ZLS-Only' hypothesis
166 (Reindl, Bandini & Tennie, 2018). In line with this, Hayashi, Mizuno and Matsuzawa (2005)
167 suggested that nut-cracking could potentially be individually reinnovated by chimpanzees. Some
168 field reports support these views; for example, a report of nut-cracking in Cameroon (Morgan &
169 Abwe, 2006) passes the 'information barrier' of the N'Zo-Sassandra River (McGrew, Ham,
170 White, Tutin, & Fernandez, 1997). This report can be regarded as the outcome of a natural quasi-
171 latent solution test (*sensu* Bandini & Tennie, 2018), as this pattern strongly suggests that that
172 nut-cracking was (re-)innovated in two, culturally separate, wild communities (Tennie et al.,

173 2009, p. 2406). Though, again, these results should be considered in the light of the fact that they
174 are supported by second hand reports, sounds in the forest and finding of tools.

175 If all underlying steps of the nut-cracking behaviour are also found to be reinnovated by a
176 naïve, captive, chimpanzee in a culturally separate “island” of individuals (Tennie, Braun,
177 Premo, & McPherron, 2016; Tomasello, 1999) then the behaviour would (by definition) cease to
178 be a putative example of an animal CDT. This would support the ZLS hypothesis and would
179 suggest that chimpanzees are capable, in principle, of individually learning the basic behaviour
180 form underpinning nut-cracking; demonstrating that social learning is not *required* for this to
181 occur. Importantly, it should be noted that social learning is likely to play a role in the process of
182 chimpanzees understanding that nuts are a food source and, in addition, that they can be
183 considered a ‘safe’ food (Hopper, Schapiro, Lambeth, & Brosnan, 2011). Although this process
184 is important for the frequency of nut-cracking within and across populations, our study is
185 concerned with the mechanisms underlying tool-use aspect of the behavioural form of nut-
186 cracking.

187 Therefore, here we test two competing hypotheses: chimpanzee nut-cracking as a culture
188 dependent trait (the “CDT hypothesis”) versus chimpanzee nut-cracking as a behaviour that can
189 be individually learned (re-innovated; Bandini & Tennie, 2017), but whose expression may
190 nevertheless be facilitated by non-copying variants of social learning (the “ZLS hypothesis”,
191 compare Tennie et al., 2009; in press). Simply, the ZLS hypothesis posits that nut-cracking
192 should emerge in a ‘baseline’ condition, i.e., without requiring social learning. Contrastingly, the
193 CDT hypothesis argues that copying variants of social learning are necessary for the emergence
194 of nut-cracking in a naïve sample.

195 Thus far, various chimpanzee behavioural traits, previously assumed to be culture
196 dependent, have been reinnovated by naïve, captive subjects in latent solution tests (Bandini &
197 Tennie, 2017, 2019; Menzel, Fowler, Tennie, & Call, 2013; Motes-Rodrigo et al., 2019; Neadle
198 et al., 2017; Tennie et al., 2009; Tennie, Hedwig, Call, & Tomasello, 2008). These behaviours
199 ('latent solutions'; Tennie et al., 2009), were reinnovated without requiring any observation (or
200 teaching). This does not, however, mean that social learning does not play any role in the
201 innovation likelihood of these behavioural forms. Indeed, several variants of non-copying social
202 learning (the specific mechanism was not directly tested in the studies mentioned above) greatly
203 facilitate the innovation likelihood of the behaviour in both captive and wild chimpanzees
204 (therefore affecting the observed frequencies of behaviours within and across populations;
205 Tennie et al., in press; Bandini & Tennie, 2017, 2019).

206 In the current study, we tested both the CDT and the ZLS hypothesis predictions for nut-
207 cracking. In 2010, Tennie et al. hypothesised that nut-cracking would be within the chimpanzee
208 ZLS, but that it may simply have a relatively low baseline probability of reinnovation (i.e., it is at
209 the very edge of the chimpanzee ZLS). We were able to test both hypothesis by applying the
210 extended latent solutions testing methodology (first described in Bandini & Tennie, 2018). This
211 method first starts by testing for the reinnovation of the target behavioural form (here nut-
212 cracking) in completely naïve chimpanzees (we ensured naivety by asking keepers of the
213 animals' previous experiences of the behaviour) – thus testing the ZLS hypothesis. If the
214 behaviour does not appear in this baseline, subjects are then provided with incremental levels of
215 social learning information. The particular methodology followed in this study allows for the
216 examination of the role of individual learning (initial baseline test), then subsequently for end-

217 state emulation, goal emulation and finally action copying (imitation) in the emergence of the
218 target trait.

219

220 **Materials & Methods**

221 **Subjects**

222 The subjects were 13 chimpanzees ($M_{\text{age}} = 31.08$; $SD = 1$; female = 9, male = 4; See
223 Table 1; *Pan troglodytes sp.*). All subjects lived within a single group and comprised the entirety
224 of that group, except for one individual (C13), which, due to group transfers within the
225 zoological institution throughout the duration of this study, was introduced into the group before
226 the start of the second condition (therefore C13 did not participate in the baseline condition).
227 Subjects were provided with scatter feeds, consisting primarily of vegetables with some fruit in
228 the morning (approx. 10am) and again in the afternoon (approx. 3pm). The subjects were housed
229 in two enclosures throughout the course of the study; between June 2017 and April 2018 subjects
230 were housed in the “conversion” enclosure, from April 2018 until the end of the study subjects
231 were housed in the “Eden” enclosure. Both enclosures consisted of two indoor areas and an
232 outdoor area (two smaller areas in the case of conversion), with separate management areas
233 (away from the observation of visitors). Subjects could be observed through glass panes in all
234 public areas and mesh in management areas, observations used in this study were obtained from
235 both. Within the main enclosures, subjects had access to enrichment devices, such as climbing
236 frames/ropes, hanging feeders and nesting baskets. Other enrichment devices are regularly
237 provided by keepers.

238

239

TABLE 1 ABOUT HERE

240

241 Prior experience questionnaire

242 In order to exclude any possible influence of social learning on the results of this study,
243 keepers filled out questionnaires and were interviewed (designed and distributed by EB at the
244 zoological institution) about prior tool use behaviour. The use of this questionnaire was approved
245 by the University of Birmingham STEM ethical review committee (ERN_17-1729). The section
246 of the questionnaire relevant to this study can be found in S1. The questionnaire asks keepers to
247 provide details on behaviours relating to “*Using one object to bang on, or hit, another: usually,*
248 *this means the use of a hard object to bang on or hit another, often hard, object. This may be*
249 *with the aim to crack or break open the latter object, or to remove a substrate. Here, we are*
250 *interested in any hammer-like behaviours, regardless of the objects involved*”. This definition
251 encompasses nut-cracking and similar actions, such as hammering behaviours. No instances of
252 nut-cracking were reported in the questionnaire; however, a keeper described how one individual
253 (C6; female; age 9) used a stone to tap on the glass of the outdoor enclosure. All but one keeper
254 reported that the chimpanzees were frequently witnessed using their teeth to crack nuts, although
255 they have never been provided with shelled macadamia nuts.

256 Ethical statement

257 All participation in this study was voluntary, and subjects were allowed to leave the
258 testing area at any point throughout the session. Subjects’ usual feeding and cleaning routines
259 were followed, minimising disruption to the animals. The experimental phase of this study was
260 ethically reviewed and approved by the University of Birmingham Animal Welfare and Ethical
261 Review Body (UOB 31213) and Twycross Zoo Research Committee (TZR-2017- 013),
262 following guidelines provided by SSSMZP, EAZA, BIAZA, WAZA on animal welfare and
263 research in zoological institutions; this study also received a letter of support from BIAZA. This

264 study adhered to legal requirements of the UK, where the research was carried out, and adhered
265 to the ASP principles for the Ethical Treatment of Primates.

266 **Motivation tests**

267 This phase took place between 13th June 2017 and 27th September. Prior to starting
268 experimental testing, it was important to ensure that the subjects were sufficiently interested and
269 motivated to access the novel food reward (macadamia nuts) used in this study. To motivate the
270 chimpanzees to try the nut kernels when first presented, the first stage involved a trusted
271 individual (a keeper that has worked with the subjects for more than five years) first eating a
272 different familiar food in front of the subjects (here we used dried raisins and berries). The
273 keeper attracted a subject's attention by calling their name, and then ate a single item of the
274 familiar food (i.e., one raisin) in view of them. This process was repeated until each individual
275 had observed the consumption in a group context. The subjects were then provided with the same
276 food and required to eat it before moving onto the next step. As this food was familiar, this
277 occurred in every case. The next stage was to introduce the *novel* food (macadamia nut kernels
278 already without their shells). The same keeper ate a single macadamia kernel in the same way as
279 with the familiar foods. Again, each individual was given a demonstration (sometimes groups of
280 individuals could watch together as subjects were not separated during this part of testing). Once
281 each individual had observed the consumption of the nuts at least once, they were provided with
282 a macadamia kernel, again within a group context. This process was designed to increase the
283 likelihood that the subjects would consume the novel food, as prior research has shown that
284 captive chimpanzees can vary substantially in their acceptance of novel food sources
285 (Visalberghi, Yamakoshi, Hirata, & Matsuzawa, 2002). Despite the neophobia reported by
286 Visalberghi et al. (2002), we chose to replicate their 'trusted' human demonstrator condition in
287 an attempt to maximise the likelihood that the subjects would consume the macadamia nuts. In

288 addition to this, the ‘motivation tests’ were used to ensure that the nuts were palatable to the
289 subjects; therefore, should they have succeeded in cracking a nut, they would be sufficiently
290 motivated to continue doing so. Equally, during the demonstration conditions (see below) the
291 nuts provided might then serve as a suitable motivator to encourage the chimpanzees to attempt
292 to reinnovate or copy the behaviour. We required at least half the chimpanzees to eat the novel
293 nuts before starting testing, this was to ensure that the motivation testing did not go on for too
294 long, as these tests were carried out within a group context, it was likely that lower ranking
295 individuals would never be allowed access to the nut kernels.

296 **Test conditions**

297 Each trial was video recorded, starting when the subjects were given access to the testing
298 apparatus. The study took place between the morning and afternoon feeds; this time was chosen
299 as it complemented the daily routine of the keepers and animals whilst providing the maximum
300 testing time possible. The timings changed once the chimpanzees moved enclosure as the
301 keepers were able to provide the afternoon feed without needing to move the subjects outside the
302 testing area. Average trial length before the move was 3 hours ($n = 8$), after the move it was 5
303 hours 41 minutes ($n = 12$). Overall, there was a total of 92 hours and 18 minutes observation
304 time ($M_{\text{trial length}} = 4 \text{ hours } 37 \text{ minutes}$). The experimenter (DN) was present throughout each trial.

305 This study used a stepwise design, where each condition (see Figure 1) was followed by
306 the next in the event that the behaviour was not expressed in the first condition after five trials.
307 For example, the “End state” condition was only implemented in the event that the behaviour
308 was not reinnovated in the “Baseline” condition. Testing ended once the subjects had received 5
309 trials with full action demonstrations.

310 **FIGURE 1 ABOUT HERE**

311

312 In all of the conditions, behaviours were first live coded. If, during live coding, any
313 attempts at nut-cracking were identified then these were checked against videos and then second
314 coded for reliability analysis. Here we defined nut-cracking in terms of tool use, therefore, to
315 qualify as nut-cracking, the subject needed to use an object as a hammer to attempt to break open
316 the nut, whilst resting the nut on another hard surface (the anvil). Video recordings were
317 focussed on the experimental hammer and anvil set up (described below), however DN was
318 present at all times to observe any behaviours that might have occurred outside of the camera
319 frame.

320 **Materials**

321 The same apparatus set up was used in all conditions, and any changes to these conditions
322 are noted in the relevant section. To set up the apparatus, DN entered the outdoor enclosure and
323 secured a large wooden log (50cm tall x 40cm approx. diameter; that would serve as an “anvil”)
324 to an upright portion of the climbing frame (which had a horizontal crossbeam, to ensure that the
325 anvil could not be removed; see Figure 2). The anvil was secured to the upright climbing frame
326 using two 1m long, 8mm thick, PVC coated, steel rope passed through two (12mm diameter)
327 holes drilled through the anvil (located $\frac{1}{4}$ and $\frac{3}{4}$ of the way down the log). Both ends of the rope
328 had a loop (secured by five ‘clips’ at each point, ‘clips’ used two, 8mm, nuts and bolts (tightened
329 using an electric drill), which was too large to pass through the hole in the anvil, and a steel
330 padlock attached the two ends. Two of these securing attachments were used as a failsafe
331 measure (see Figure 2).

332 FIGURE 2 ABOUT HERE

333

334 A wooden “hammer” was also attached to this structure (wooden, rather than stone,
335 hammers were chosen as they were more secure in their attachment to the rope). The hammer

336 consisted of a 30cm long x 15cm diameter log – approx. weight 2.5 kg – with a 12mm hole
337 drilled through half way along (see Figure 2). Hammer length was chosen based on the
338 descriptions of hammers used in wild populations to crack coula nuts (20-80cm long; Boesch &
339 Boesch, 1983). Our diameter was chosen to be larger than these wild hammers (4-10cm in the
340 wild; Boesch & Boesch, 1983) in the interest of safety being more likely to remain attached to
341 the securing attachment (see below). As a result of this increased diameter the hammers were
342 slightly heavier than the majority of those used in wild populations (77% of which were less than
343 2kg; however, our hammers were still within the 2-4kg larger range described in wild
344 populations; Boesch & Boesch, 1983).

345 The hammer was attached to the anvil's own securing attachment by creating a looped
346 end in another (1.5m) length of the same steel rope; the loop was passed onto the top securing
347 attachment (of the anvil) and the loose end was secured to the hammer (by passing the loose end
348 through the drilled hole and then securing with another five clips). The hammer was then moved
349 less than 1m from the anvil (see Figure 3).

350

351

FIGURE 3 ABOUT HERE

352

353 The keepers then scattered three macadamia nuts (in their shell) per individual (i.e., 3
354 nuts x 13 individuals = 39 nuts) throughout the enclosure, avoiding a 2m radius around the
355 hammer and anvil set-up. The macadamia nuts were distributed at the same time as a regular
356 scatter feed – just prior to the subjects being released into the outdoor enclosure. The unshelled
357 weight of the nuts (around 1g average across 10 measurements) was taken from the
358 chimpanzees' usual allowance of nuts for the week (this was to maintain the dietary health of the

359 subjects, at the testing institution's request). Once the attachments had been checked by DN and
360 at least one keeper, all humans exited the enclosure and the chimpanzees were allowed in the
361 enclosure. Just prior to the chimpanzees being allowed access, video cameras (SONY HDR-
362 CX330e), set at two points framing the apparatus (to better capture various angles), on tripods,
363 were set to record. DN was also present to live code relevant behaviours (see Table 2) that
364 occurred outside of the frame of the fixed cameras.

365 **Baseline condition**

366 This test condition took place between 15th October 2017 and 30th November 2017.

367

368 FIGURE 4 ABOUT HERE

369

370 In order to examine whether the subjects would individually reinnovate the target nut-
371 cracking behaviour, it was necessary to test subjects without providing any social information
372 beforehand. All sessions began between 10 am and 12 noon, when keepers provided the
373 chimpanzees' scatter feed (mainly consisting of vegetables and fruit). All sessions were
374 conducted in the "Outdoor 1" section of the enclosure (see Figure 4); however, subjects had
375 access to both indoor areas throughout the session.

376 **End state condition**

377 This phase of the study was completed between 15th January 2018 and 18th May 2018.

378 However, after the first two trials (15th January 2018 and 17th January 2018) the weather

379 conditions at the testing institution became so harsh that the subjects would often refuse to leave

380 the indoor enclosure. Thus, testing was paused until 14th May 2018, after which the final three

381 trials were completed on the 14th, 16th & 18th May. Between testing in January and May subjects

382 were moved from "Conversion" (their previous enclosure) to a new enclosure: "Eden" (see

383 Figure 5); subjects were therefore given one month after moving to the new enclosure to settle in
384 before testing resumed.

385

386

FIGURE 5 ABOUT HERE

387

388 In this condition, we placed three macadamia nuts, shells and kernels, which had been
389 split in half (see Figure 6) on top of the anvil (in the “Conversion” enclosure this was in
390 “Outdoor 1” and in “Eden” this was in “Habitat 1”). This condition was designed to specifically
391 trigger stimulus/local enhancement (defined as when an animal’s attention is drawn to an
392 object/location as a result of some change in the environment). In this condition, we drew a
393 subject’s attention to the anvil and hammer (and the nuts) by adding the cracked nuts on top of
394 the anvil.

395

396

FIGURE 6 ABOUT HERE

397

398 This condition was carried-out as the chimpanzees failed to individually reinnovate the
399 nut-cracking behaviour in the baseline condition and followed the exact same protocol as the
400 individual learning condition, described above. During the design process the study originally
401 included an extra condition between the “Baseline” and “End state” conditions, called “Local
402 Enhancement”. In this condition it would have been made clear to the subjects that a kernel is
403 inside the macadamia nut and therefore that it constitutes a food source by shaving half of the nut
404 shell away to reveal the kernel inside (see Bandini and Tennie, 2018). However, some of the
405 chimpanzees in this study cracked the shells of the macadamia nuts with their teeth and

406 subsequently consumed the kernels (see Figure 7), rendering this condition unnecessary. This
407 was unexpected as Boesch and Boesch (1983) state that they never observed a wild chimpanzee
408 cracking coula nuts with its teeth; macadamia nuts (as used in this study) have a break strain of
409 between 1800-4000N (Schüler, Speck, Bührig-Polaczek, & Fleck, 2014), which is comparable to
410 coula nuts and substantially less than required for panda nuts (Boesch, Bombjaková, Boyette, &
411 Meier, 2017).

412

413

FIGURE 7 ABOUT HERE

414

415 **Ghost condition**

416 This phase of the study was completed between 19th July 2018 and 10th August 2018. The
417 ghost condition involved a significant increase in the level of social information provided to the
418 subjects. In this condition, the hammer and anvil set-up were still present inside the enclosure,
419 along with three macadamia nuts per individual (scattered throughout “Eden Habitat 2”) and a
420 further three nuts (this time whole and uncracked nuts, inside the shell was provided) placed on
421 top of the anvil. Additionally, a replica of the equipment inside the enclosure (i.e., a hammer and
422 anvil set up) was placed outside the enclosure, visible through the mesh near the subjects’
423 sleeping area (see Figures 8 & 9); DN was also present, standing to the left of the anvil.

424

425

FIGURE 8 ABOUT HERE

426

427 A reel of clear fishing line (0.65mm diameter; 18kg break strain) was attached to the
428 hammer and passed through a section of mesh, allowing the hammer to be raised (between 80
429 and 50cm) above the anvil, via a pulley-like system (see Figure 9). A keeper steadied the

430 hammer before dropping it onto the nut, thus increasing the likelihood of the hammer cracking
431 the nut in the shortest possible time. Once the subject was clearly attending the apparatus (a
432 subject's attention was gained by calling their names), the hammer was dropped onto a nut
433 (which was placed in a groove in the centre of the anvil), cracking the nut open- this did not
434 always occur first time and may have required multiple attempts. A keeper then approached the
435 anvil and gave the subject who watched the demonstration the cracked nut. The device was then
436 rebaited with a new nut in the centre of the anvil. This procedure was repeated for a further 29
437 nuts (equalling a total of 30 demonstrations; with the exception of trial 4, where the line broke,
438 meaning that the trial was halted after 17 demonstrations). Subjects had access to the testing
439 apparatus during the course of the ghost trials. One camera was used to record the subjects'
440 interactions with the test apparatus, whilst the other was used to record subjects observing the
441 ghost demonstrations; chest mounted GoPro (Hero5 Session) cameras were also used to record
442 demonstrations and attention from the demonstrator's perspective. In both this condition and the
443 Full Action Demonstration condition, observing subjects were considered to be those in the
444 enclosure immediately in front of the demonstration area (far left sleeping area in Figure 8)
445 oriented towards the apparatus/demonstrator (i.e., not with their back turned).

446

447

FIGURE 9 ABOUT HERE

448

449 The ghost condition (inspired by Hopper, Lambeth, Schapiro, & Whiten, 2008) fulfils the
450 primary stipulation of learning by emulation (Tomasello et al., 1993); i.e., the learner should not
451 copy the motor patterns of the demonstrator. In this ghost condition, the motor patterns required
452 for nut-cracking were not demonstrated, making it impossible for the chimpanzees to copy the

453 actions (Heyes, 1994). Thus, if the behaviour were to occur following this condition, it could be
454 inferred that the results of the actions were replicated rather than the actions themselves (Hopper,
455 2010; Whiten et al., 2004).

456 **Full action demonstration condition (human demonstrator)**

457 This phase of the study was completed between 16th August 2018 and 6th September
458 2018. The full action demonstration condition was the first one that allowed for the possibility of
459 action copying. In this condition, DN was positioned outside the enclosure (in the same location
460 as the ghost condition). An anvil was placed in the same location as in the ghost condition (see
461 Figure 8), with a hammer placed 1m from the anvil (both pieces of wood were identical to those
462 in the subjects' enclosure). The researcher then attracted a subject's attention by calling their
463 name and proceeded to crack a nut, on top of the anvil, using the hammer. Note, it was not
464 possible to exclude the fact that multiple subjects may attend to the call of one individual –
465 subjects attending to a demonstration were coded from videos. The experimenter used the
466 hammer in a vertical manner, in the same orientation to the hammer in Figure 9 (see Figure 10),
467 raising it to eye level and then hitting down onto the nut, resulting in the nut breaking open. The
468 orientation of the hammer was used to attempt to control for hammer orientation between the
469 ghost and full action demonstration trials. Once cracked, the kernel was provided to the subject
470 by a keeper (see Figure 10D) and the device rebaited with another nut. A total of 30 nuts were
471 cracked using this procedure in each trial; a nut was not cracked until DN considered that the
472 target subject was attending to the demonstration. A maximum of 30 nuts was used based on
473 advice from keepers that not all subjects would attend to, or even approach, the demonstrations
474 (therefore, for all subjects to observe, trials could have continued indefinitely which would have
475 been unfeasible).

476

477 FIGURE 10 ABOUT HERE

478

479 **Coding/analysis of behaviours**

480 *Coding procedure*

481 Trials were live coded using the ethogram in Table 2. Following live coding a formal
482 coding procedure from video was followed. DN coded each trial in turn and a second coder
483 (MT), naïve to the hypothesis of this study, second coded 100% of the behaviours identified
484 (N=31) along with an equal number of “dummy” clips where a subject was in the frame but DN
485 did not identify a behaviour occurring to test for inter-rater reliability (acceptable Kappa would
486 be 0.6; Cohen, 1968; calculated using R package "irr" v.0.84.1; Gamer, Lemon, Fellows, & Singh,
487 2019). Note that the behaviours in Table 2 rely on the previous behaviour in order for them to be
488 coded; e.g., if the subject picked up the hammer without first placing a nut on the anvil then the
489 hammer behaviour would not be coded. This was to attempt to parse hammer centred
490 play/exploration from attempts at nut-cracking.

491

492 TABLE 2 ABOUT HERE

493

494 *Analyses*

495 After a behaviour has been reinnovated, social facilitation cannot be excluded as a
496 potential reason for the behaviour’s continued emergence in other group members (Bandini &
497 Tennie, 2018; Tennie & Hedwig, 2009). Given an N of 1, it is not possible to perform inferential
498 statistics on acquisition times or rates between individuals. However, descriptive statistics were
499 used. All descriptive statistics were produced using R v.3.5.2 (R Core Team, 2013).

500 **Results**

501 Motivation test

502 During the motivation test, seven subjects (54% of sample; C3, C7, C9, C8, C5, C12 &
503 C13) consumed at least one macadamia nut provided by the keeper, leading to the conclusion
504 that macadamia nuts palatable to most of subjects included in this study (although note that
505 dominance hierarchies/individual personality characteristics may have interfered with certain
506 individual's ability/motivation to access the nuts).

507 Reliability analysis

508 The results of a Cohen's Kappa analysis revealed a strong level of agreement between
509 coders ($\kappa = .85$, $p < .001$).

510 Attempts at nut-cracking

511 None of the individuals in this study attempted to crack open the nuts using a tool in any
512 of the conditions described above. As there was never any evidence of nut-cracking, or
513 approximations of it, all conditions were completed (as explained in the methods section).

514 Attempts recorded within the ethogram

515 The coding procedure identified the following behaviours from the ethogram: place ($n =$
516 26; first occurring during baseline condition trial 2 but distributed across baseline ($n = 7$), end
517 state ($n = 15$) and ghost ($n = 4$) conditions), hold ($n = 1$; occurring during baseline condition trial
518 2), stamp ($n = 2$; occurring during baseline condition trial 2) and throw ($n = 2$; occurring during
519 baseline condition trial 2). Recordings of "place" were identified in C5 ($n = 7$), C6 ($n = 18$) and
520 C7 ($n = 1$) across all conditions apart from full demonstration. In only one instance did a "hold"
521 event follow "place", this concerned C6 during baseline condition trial 2; who was also the only
522 individual to "stamp" on or "throw" the nuts. It is unclear whether throwing was an active effort
523 to break the nut or simply an act of frustration/play as it did not appear that the throws were

524 aimed at any hard surface, nor were there ever attempts to retrieve the nuts afterwards by the
525 throwers.

526 *Alternative techniques*

527 Anecdotally, the majority of subjects (if not all) were witnessed, at least once, attempting
528 to crack the nuts with their teeth (with some individuals succeeding; see Figure 7). Male
529 chimpanzees ($n = 4$) were the only individuals observed (by DN) successfully accessing the nut
530 kernel using this method. The teeth cracking technique was first observed in the baseline
531 condition and persisted throughout the study. These behaviours were not captured on the main
532 videos as the cameras were facing the apparatus throughout the trial (to ensure that any attempts
533 at using the apparatus to crack the nuts were captured), also some subjects were not visible
534 throughout; therefore, any attempt to quantify these behaviours would be inaccurate as it would
535 likely present only part of the actual series of events.

536 *Observers Ghost and Full Action Demonstration Conditions*

537 Occasionally the identity of the observer could not be ascertained from video footage; in
538 these cases, the individuals were not included in the calculations below. Furthermore, as
539 participation in the study was voluntary, and subjects were free to approach and interact with the
540 testing apparatus whenever they chose, not all subjects observed all the demonstrations provided.
541 Some subjects ($n = 2$; C5 & C11) never observed the demonstrations in either condition; whilst
542 other subjects never observed demonstrations in the ghost ($n = 3$; C5, C13 & C11) or full
543 demonstration conditions ($n = 4$; C5, C11, C1, C10). Overall, 77% of subjects ($n=10$) were
544 coded as observers in the ghost condition and 69% of subjects ($n=9$) were coded as observers the
545 full demonstration condition; there was an average of 2.48 observers per ghost demonstration
546 and 2.99 observers per full demonstration.

547 **Discussion**

548 We found no evidence of nut-cracking with a tool, or any approximation at this, at any
549 point during the course of this study. Thus, our sample of 13 naïve chimpanzees failed to
550 reinnovate or socially learn the behavioural form of nut-cracking. At first, it would seem our
551 findings support the CDT hypothesis, in that nut-cracking behaviour was not reinnovated in our
552 initial baseline condition. However, our study also consisted of various social learning test
553 conditions – including one that demonstrated the necessary action patterns for nut-cracking to the
554 chimpanzees. This condition allowed for the possibility of action copying being a requirement of
555 the behaviour, as has recently been claimed (Estienne, Cohen, Wittig, & Boesch, 2019). Even so,
556 nut-cracking was not acquired by the subjects. Therefore, our study does not provide conclusive
557 evidence for either the CDT or the ZLS hypothesis. Below we discuss three possible
558 explanations for our null result and the general disparity in studies of chimpanzee nut-cracking.

559 **Conspecific models**

560 The findings of this study raise the question as to why some chimpanzee populations in
561 the wild regularly crack nuts (on average 270 nuts per day for as long as 2 hours 15 minutes in
562 Taï Forest; Boesch & Boesch-Achermann, 2000) whereas captive chimpanzees (in this sample
563 and others; Funk, 1985) seem to rather consistently fail to acquire the behaviour, even after
564 demonstrations. A first possibility for the disparity between wild and captive data is that nut-
565 cracking is indeed a CDT and requires the learner to imitate a conspecific demonstrator (Boesch,
566 1996). In this study we used human demonstrators, which may not have been considered ‘good’
567 enough models for the chimpanzees. Indeed, some research has shown that chimpanzees are
568 more proficient social learners from conspecific models as compared to videos or human models
569 (Hopper, Lambeth, Schapiro, & Whiten, 2015). However, in contrast, others have instead
570 claimed that it is possible for chimpanzees to “learn” nut-cracking from human demonstrators
571 (see findings of Ross, Milstein, Calcutt, & Lonsdorf, 2010 but also review of other related

572 studies Table 3 (p. 230) of Ross et al. 2010). Concurrently, other studies have found that, even
573 with conspecific demonstrators, sometimes captive chimpanzees fail to acquire complex
574 behaviours such as nut-cracking (Funk, 1985) or behaviours which strictly require imitation
575 (Clay & Tennie, 2018; Tennie, Call, & Tomasello, 2012; Tomasello et al., 1997). Although it
576 might have been interesting to observe the chimpanzees' reaction to a conspecific demonstrator
577 in this study, we did not have the resources to train a chimpanzee to act as a demonstrator, but
578 we encourage interested researchers who do have the resources to replicate this study, and
579 include a conspecific demonstrator to observe whether this affects the findings presented here.

580 **Behavioural flexibility**

581 An alternative explanation for the fact that nut-cracking did not emerge in this study is
582 that the chimpanzees were hindered by their lack of behavioural flexibility, a commonly
583 recorded phenomenon in chimpanzees (e.g., Harrison & Whiten, 2018). The chimpanzees in the
584 current study seemed to become fixated on one solution to open the nuts: i.e., the use of their
585 teeth. The chimpanzees may have relied on this technique due to their pre-existing knowledge on
586 how to crack softer-shelled nuts (such as peanuts and walnuts), which they are often provided
587 during their feeds at the testing institution. These nuts are easily cracked open by apes using
588 teeth (DN; personal observation, keeper reports and see also Visalberghi et al., 2008 for
589 measurements on the required force for different types of nuts). The heuristic (Marsh, 2002) in
590 this case may be that nuts (in general) *can* be opened with teeth – and indeed our macadamia
591 nuts were no exception. Chimpanzees have been shown to be reluctant to display behavioural
592 flexibility in abandoning a previously successful solution (see Harrison & Whiten, 2018;
593 Hrubesch, Preuschoft, & van Schaik, 2009; but see also Manrique, Völter, & Call, 2013). Thus,
594 it is possible that the first individual to successfully crack a nut with the use of teeth (see Figure
595 7), facilitated this behaviour within the group and/or that other individuals independently

596 converged on this method, and then the subjects were unable to innovate a new method, even if
597 cracking the nuts with a tool would have been mechanistically easier/more efficient (this
598 possibility is also in line with cultural founder effects; Tennie et al., 2009).

599 **Sensitive learning period**

600 Based on the literature, the most likely explanation for the findings in this study is that
601 the chimpanzees may have simply been outside of their sensitive learning period for nut-
602 cracking. Previous studies on nut-cracking in wild chimpanzees have reported that before 3.5
603 years, juvenile chimpanzees are unable to express the full nut-cracking behavioural form (Inoue-
604 Nakamura & Matsuzawa, 1997; Matsuzawa, 1994). However, juvenile chimpanzees (as young as
605 1.5 years old) that had been exposed to the materials required for nut-cracking at various
606 ages/developmental stages were able to perform the basic actions of the behaviour (put, hold, hit
607 and eat), but not combine them in the required order to perform the full nut-cracking behaviour
608 (Inoue-Nakamura & Matsuzawa, 1997). Indeed, recent research in wild chimpanzees shows an
609 exponential increase in nut-cracking between 5 and 6 years of age, though the first signs were
610 observed in 3-4-year-old individuals (Estienne et al., 2019) in line with the concept of maturation
611 (Corp & Byrne, 2002). This finding suggests a certain level of developmental prowess required
612 to express nut-cracking, perhaps somewhere between maturation effects of the body and the
613 brain.

614 In addition to this lower age limit for the acquisition of nut-cracking, there also appears to
615 be an upper limit (more relevant for the current study). A 13 year longitudinal study by Biro et
616 al., (2003) found that wild chimpanzees who did not learn the basic nut-cracking skills before
617 five years old seemed unable to acquire the behaviour later on in adulthood (a similar case has
618 been documented recently for stone tool-use in long-tailed macaques; Tan, 2017). The subjects
619 tested in the current study were all outside of the hypothesised sensitive learning period for nut-

620 cracking, as the youngest subject in our sample was already 10 years old at the time of testing.
621 The youngest individual however was the only subject to display the “hold” behaviour (stage two
622 of four) in the behavioural form of nut-cracking. Our findings, coupled with those described here
623 suggest that a sensitive learning period may be a decisive factor for whether a chimpanzee will
624 start to crack nuts or not (leaving open the question how this is learned, i.e. whether it is a CDT
625 or a latent solution).

626 Given the fact that wild chimpanzees engage in an extended process of acquisition before
627 expressing nut-cracking (Matsuzawa et al., 2008), we suggest that future work considers
628 applying an even longer study time than the one employed here. It is possible that chimpanzees
629 may then individually, or socially, learn the behaviour. The social learning opportunities here
630 provided comparatively more demonstrations than related studies (5 trials with 30 nuts per
631 demonstration in our study versus 5 trials with 5 nuts per demonstration by Marshall-Pescini &
632 Whiten; 2008). Even so, the social learning opportunities that we present here were fewer
633 compared to the wild; in wild populations that express the behaviour, individuals have more and
634 longer (and perhaps also more varied) opportunities to observe nut-cracking. Equally, given the
635 potential importance of a sensitive learning period in explaining the emergence patterns of
636 chimpanzee nut-cracking (discussed in this section) we suggest that the next logical test of this
637 behaviour should aim to test younger chimpanzees between the ages of 3 and 10 years (Ross et
638 al., 2010 suggest between ages 3-7); either way, these individuals should once again be selected
639 from populations that have not been observed previously to crack nuts.

640 Though we used a within-subject design throughout our result-dependent design, we
641 would recommend that (wherever feasible) a between-subject design be used in future tests (one
642 group for each of the conditions). By doing the latter, it is possible to control for and measure the

643 time of exposure required for chimpanzees to express nut-cracking, and it would exclude
644 potential carry-over effects. However, this project would likely be an overly large undertaking
645 for any one research group, so therefore may be better suited to large scale collaborative projects
646 (e.g., the ManyPrimates project).

647 **Conclusions**

648 Although no chimpanzees in this study demonstrated nut-cracking using tools, two
649 geographically separate populations in the wild have seemingly converged on the same method
650 for cracking nuts using tools (West Africa; Whiten et al., 2001 and Cameroon; Morgan & Abwe,
651 2006). As these populations do not have access to each other, logically they must have
652 independently reinnovated nut-cracking (Byrne, 2007). However, the data from Cameroon is
653 based on procured nut cracking tools and auditory assumptions and so are an inference rather
654 than direct observations. It is possible that these tools were actually from modern human nut-
655 crackers and may not be considered evidence of chimpanzee nut-cracking in multiple
656 populations. Thus, to date, there is only concrete evidence of one culturally independent wild
657 population expressing nut-cracking. As the data from this study and wild data do not
658 unequivocally support either the ZLS or the CDT hypothesis, both remain in contention.

659 In addition to the wild data and that presented here, one chimpanzee in an experimental
660 study spontaneously reinnovated nut-cracking when provided with all the materials (Marshall-
661 Pescini & Whiten, 2008). The individual (Mawa) acquired the nut-cracking behaviour seemingly
662 without requiring any copying variants of social learning (Marshall-Pescini & Whiten, 2008).
663 However, Marshall-Pescini & Whiten (2008) fail to note the importance of these findings, by
664 assuming, based on the speed of acquisition, that “Mawa” had prior experience of nut-cracking.
665 It is worthy of note however that unlike this study and that of Funk (1985), no claim was made
666 about the naivety of the subjects. Indeed, Mawa was kept as a pet prior to residing at the

667 sanctuary where Marshall-Pescini and Whiten (2008) carried-out their study. Mawa arrived at
668 the sanctuary when he was approx. three years old with wounds from a rope where he was tied
669 up (Ferdowsian et al., 2011). As a result of this potential enculturation, or at the very least
670 deprivation, these data should be treated with caution; indeed, the generalisability of such
671 individuals to wild chimpanzees is questionable (Henrich & Tennie, 2017).

672 Excavations of chimpanzee nut-cracking sites suggest that the basic behavioural form
673 has remained constant for at least 4,000 years, and likely even longer (Mercader et al., 2007).
674 Similarly, excavations of capuchin nut-cracking sites have demonstrated that their nut-cracking
675 form has remained the same for 3,000 years, with only the tools (hammerstones) changing in
676 shape over time (Falótico, Proffitt, Ottoni, Staff, & Haslam, 2019). Indeed, if the behavioural
677 form of nut-cracking were being copied between individuals, we would expect to see some
678 changes to its form over time due to copying error alone (see Eerkens & Lipo, 2005). Lastly,
679 other extant species of primates also crack nuts using tools in the wild (long tailed macaques,
680 Gumert & Malaivijitnond, 2013; capuchins, Ottoni & Mannu, 2001), and some have even been
681 found to do so spontaneously in captivity without requiring social learning (e.g., nut-cracking is
682 a latent solution in capuchins: Visalberghi, 1987). Whilst other primate species being able to
683 spontaneously crack nuts is not evidence of a phylogenetic link; it does suggest that the
684 possibility that nut-cracking is a latent solution in chimpanzees remains. Therefore, social
685 learning may not be fully responsible for the emergence of nut-cracking in chimpanzees
686 (especially given the results of the current study, in which the chimpanzees did not acquire the
687 behaviour even after full demonstrations were provided). We acknowledge that the chimpanzees
688 in this study were captive and therefore are not subject to the same ecological pressures as their
689 wild conspecifics; that is, they would have less ‘necessity’ to reinnovate the behaviour (Fox,

690 Sitompul & van Schaik, 1999). Therefore, (parts of) this study could perhaps be replicated in a
691 wild sample, naïve to nut-cracking.

692 Therefore, the results of this study do not support nut-cracking as the first evidence of a
693 CDT in chimpanzees (see also Byrne, 2007), yet they also do not fully support nut-cracking as a
694 latent solution in chimpanzees. Instead, we conclude that the behaviour may not have emerged
695 here due to interplay of factors, including a certain level of behavioural conservatism and,
696 crucially, the fact that all the subjects were already out of their sensitive learning periods for nut-
697 cracking. We believe it is unlikely that our use of human demonstrators was the reason for the
698 failure of all our subjects to express nut-cracking, given the results of previous studies, discussed
699 above. Accordingly, we propose that future studies should adopt the methodology presented
700 here, but test unenculturated infant/juvenile chimpanzees, naïve to nut-cracking *and* to opening
701 nuts with their teeth, to remove the confounds of the sensitive learning periods and conservatism
702 (ideally tested in isolation in order to increase effective sample size). Under these conditions, it is
703 plausible that some naïve chimpanzees will reinnovate nut-cracking. Yet, on the other hand,
704 given the extended trial-and-error learning process that young wild chimpanzees engage in
705 (Matsuzawa et al., 2008) it is possible that under the relatively short term test conditions, the full
706 form of nut-cracking may still fail to emerge spontaneously, although some of the pre-requisite
707 steps to the behaviours may still develop.

708 So far, the current state of knowledge does not support the view that nut-cracking *has* to
709 be reliant on social learning as it has potentially been reinnovated in two culturally distinct
710 populations, therefore, it seems unlikely that it is a CDT. However, it is also possible that even
711 chimpanzees within their sensitive learning period would continue to fail to individually acquire
712 the skills required to crack nuts and therefore could be considered a CDT. The data at hand

713 suggest that the behavioural form of nut-cracking may only be acquired through an interplay of
714 ecological and developmental factors, i.e., chimpanzees must be in a location with appropriate
715 nuts and tool materials, during or before, their sensitive learning period. Therefore, it remains
716 possible that nut-cracking is within the species level ZLS of chimpanzees. Despite this, not all
717 individuals may realise this potential within their lifetime if they were not exposed to the
718 required ecological conditions or individual prerequisites (note that these were termed by Tennie
719 et al. (2009) as the “right” conditions that may be required). It is yet to be determined whether
720 nut-cracking’s acquisition is best described as being due to, and requiring, social learning
721 (culture-dependent) or is due to socially mediated reinnovation (latent solution). Further research
722 should consider the importance of the ecological factors explored here in addressing this
723 question.

724 **Acknowledgements**

725 We would like to acknowledge the support of Twycross Zoo throughout the process of
726 this study, without their support in material acquisition and access to subjects this study would
727 not have been possible. In particular we would like to thank Clare Ellis, Freisha Patel, Katie
728 Waller, Kris Hern, the entire ape team and the staff at Wates for their support. In addition, we
729 would like to thank Jackie Chappell, Sarah Beck, Susannah Thorpe and Josep Call for their
730 helpful discussions regarding this study. We would also like to thank Lydia Hopper, Lydia Luncz
731 and two other anonymous reviewers for helpful comments on an earlier version of this
732 manuscript. Finally, we would like to thank Matthew Thompson for his help in completing
733 second coding for reliability analyses.

Table 1 (on next page)

Subject demographic information

Note that subject names are anonymised for the purpose of the study - these codes were kept consistent throughout the study. Subject C13 is displayed in italics as she was only included in the study after the baseline condition.

ID	DoB	Sex	Rearing
C1	30/04/1976	Female	Hand
C2	09/06/1982	Male	Hand
C3	25/10/1986	Male	Hand
C4	18/08/1990	Female	Hand
C5	28/12/1990	Male	Hand
C6	10/08/2007	Female	Parent
C7	25/05/1995	Female	Hand
C8	17/06/1977	Female	Undetermined
C9	20/02/1988	Female	Hand
C10	01/01/1965	Female	Undetermined
C11	14/12/1971	Female	Undetermined
C12	05/12/2003	Male	Parent
<i>C13</i>	<i>27/12/1982</i>	<i>Female</i>	<i>Parent</i>

Table 2 (on next page)

Coding ethogram used during the live coding procedure.

This was added to throughout live coding as behaviours of interest were observed. This ethogram was provided to the second coder for reliability coding.

Behaviour	Description
Place nut	The subject places one/several nuts on the surface of the anvil. This is also coded if the subject drops the nut onto the anvil. The nut <i>may</i> roll off the anvil after being “placed” this is acceptable as it is likely due to the nut’s shape and the angle of the anvil’s surface.
Hold hammer	The subject picks up the hammer – with the nut on the anvil, by holding the wood itself or the securing attachment.
Raise hammer	The subject lifts the hammer above the nut – this may be at/below/above head height for the subject.
Drop hammer	The subject brings the hammer down onto the nut, which must be resting on the anvil. The hammer can be dropped or held in the hand the entire time. This behaviour can be repeated until the nut is cracked. The behaviour is coded each time the behaviour occurs – i.e., each time the nut is struck.
Eat nut	The subject takes the kernel of the, now broken nut and eats it. Note, this must have followed cracking of the nut by the subject.
Stamp	The subject uses their foot to stamp on the nut, which has been placed on the anvil.
Throw	The subject, whilst sitting on the anvil, throws the nut in any direction.

Figure 1

Decision tree depiction of the result dependent conditions.

If, at any stage, evidence of the behaviour was encountered then testing would cease, and the resultant learning mechanism will be attributed to the emergence of the behaviour. Each condition is continued for five trials before moving onto the next condition.

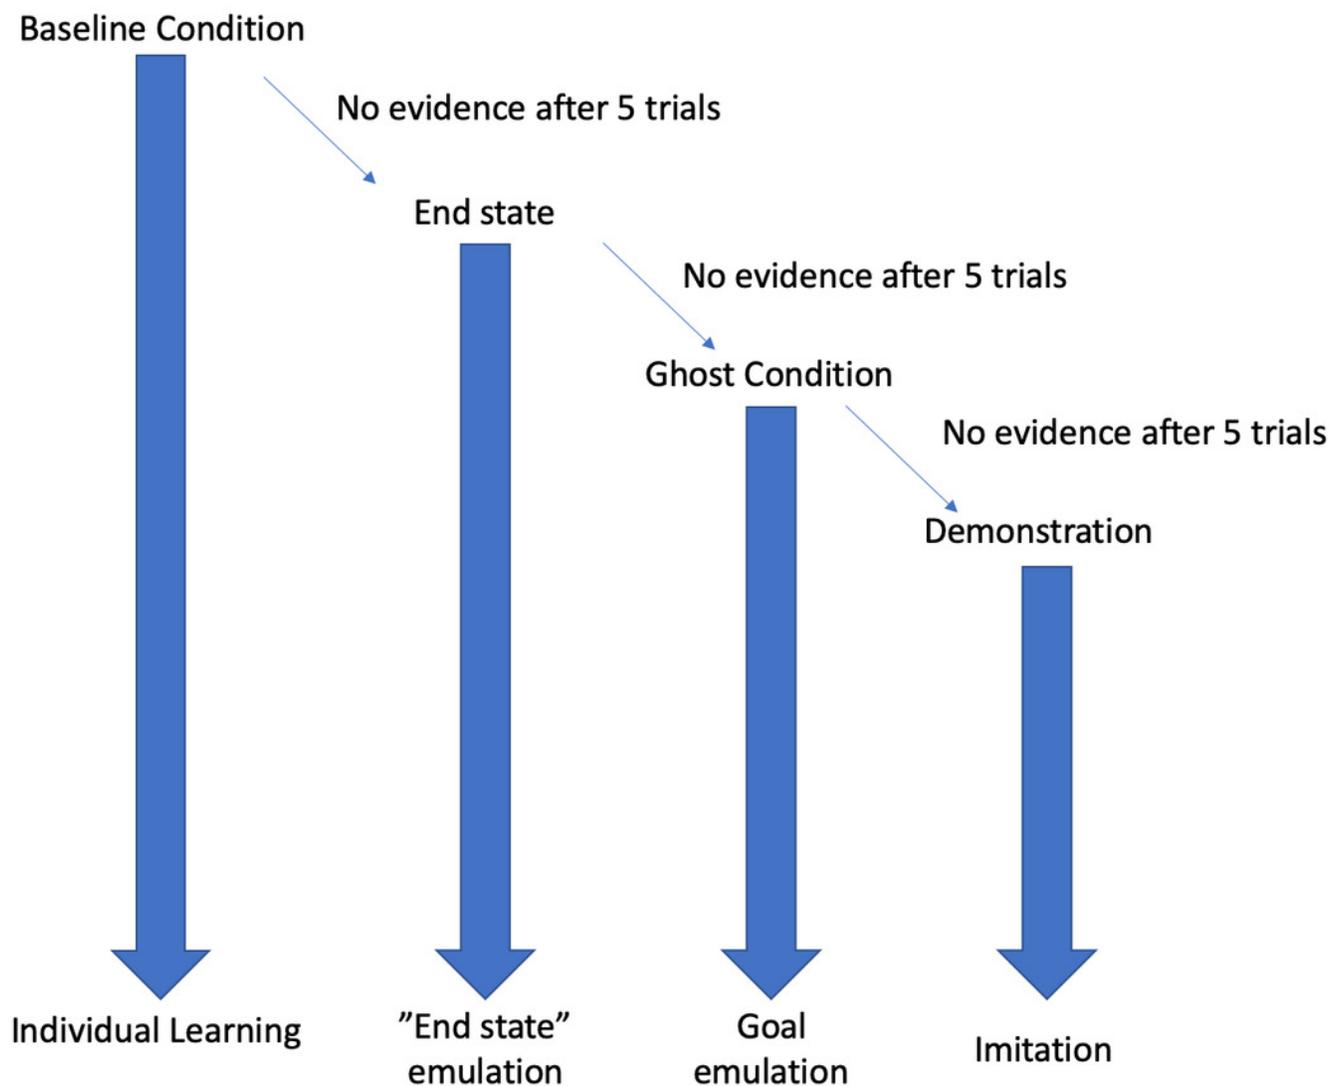

Figure 2

Securing attachment of the hammer.

Note how there are several 'clips' to act as a failsafe.

Figure 3

Hammer and anvil set up within the subjects' enclosure.

Note, the two securing attachments are passed through separate holes within the anvil and the hammer is less than 1m from the anvil (this was ensured by the length of the securing attachment of the hammer to the anvil).

Figure 4

Experimental set up for baseline condition in “conversion”

Note, the same set up was used for the first two trials of the “end-state” condition, prior to the enclosure move (see below).

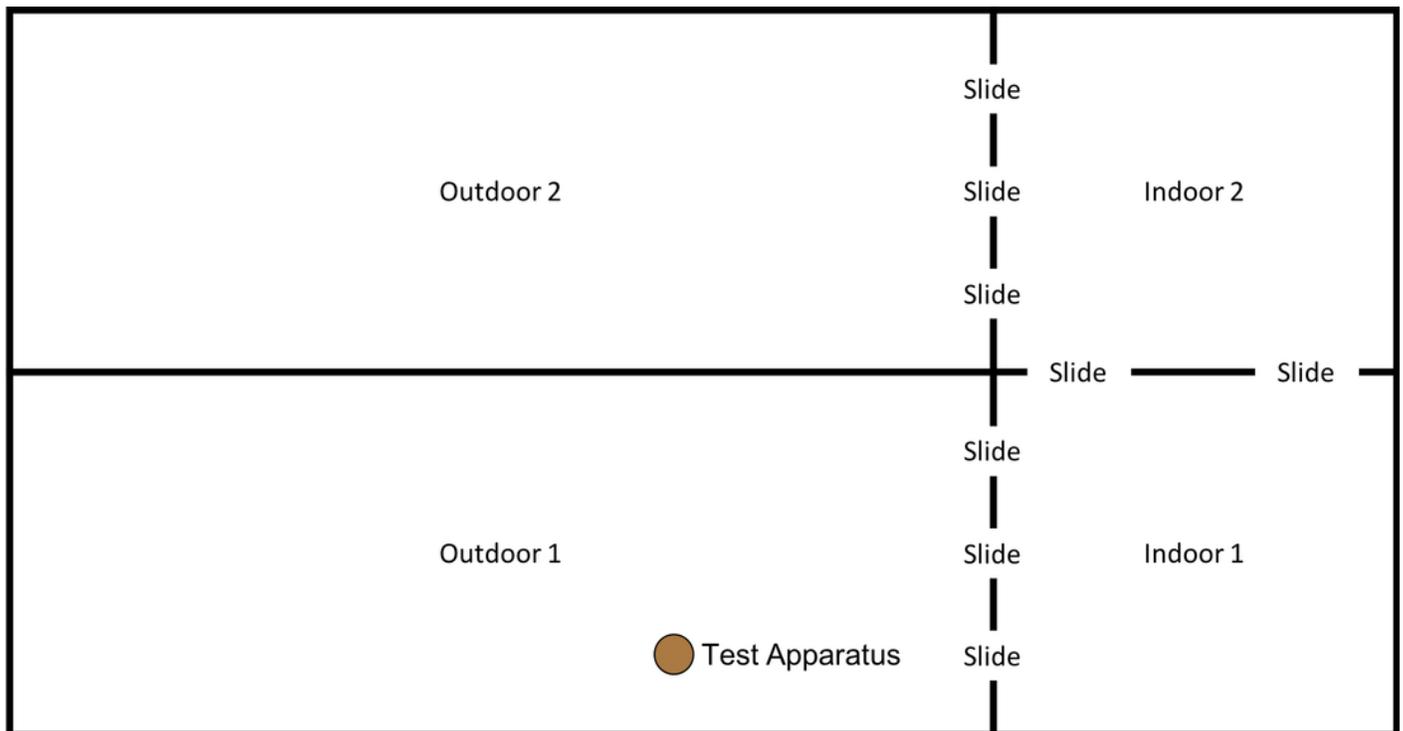

Figure 5

Experimental set up for “end-state” condition in “Eden”.

Note, subjects had access to the entirety of this enclosure throughout these trials, however, the outdoor section of the enclosure was still under construction.

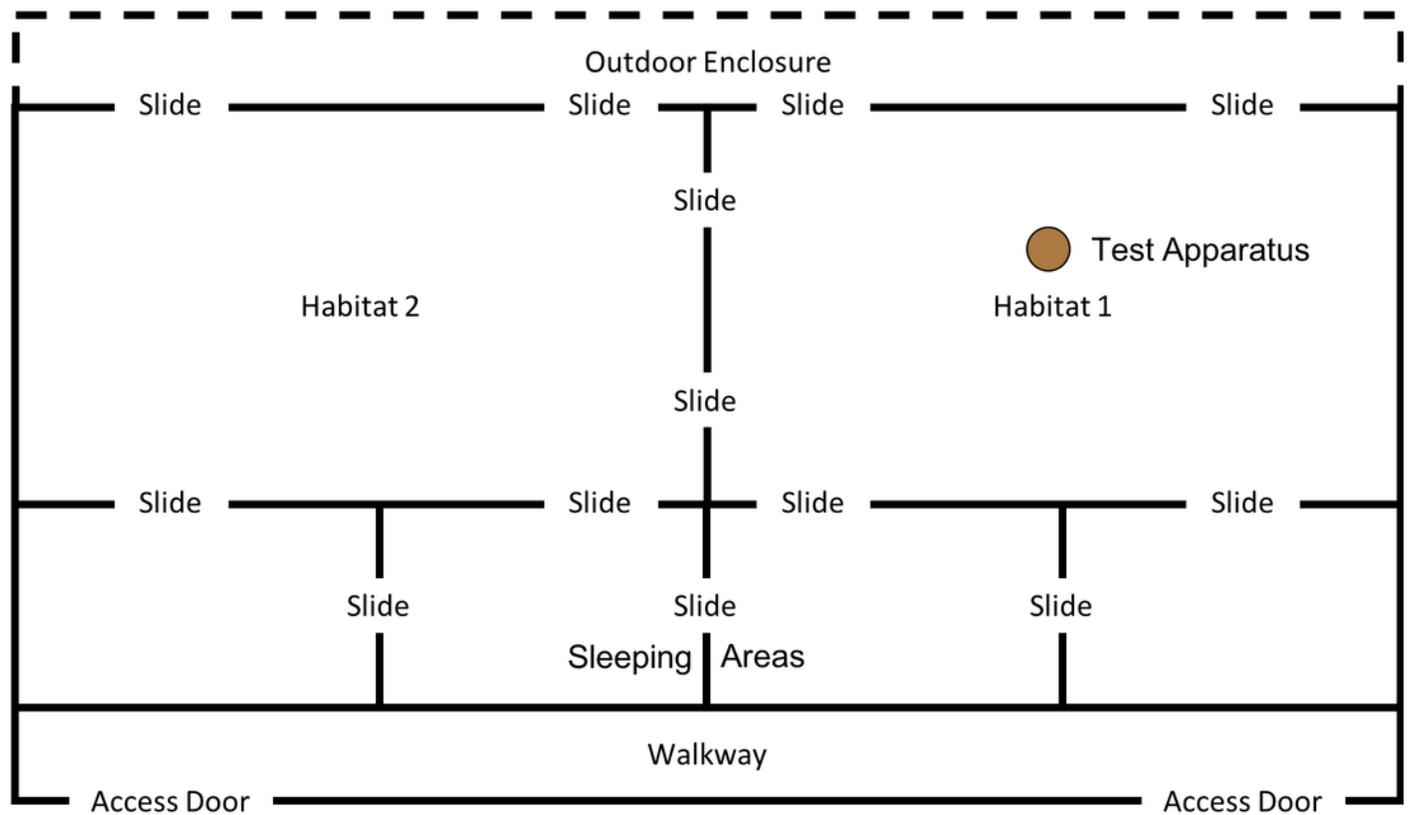

Figure 6

Macadamia nut placement and state for end-state condition.

(A) Macadamia nuts, sawn in half (with kernels left whole) for the end-state emulsion condition. (B) Nuts placed atop the anvil as described in text.

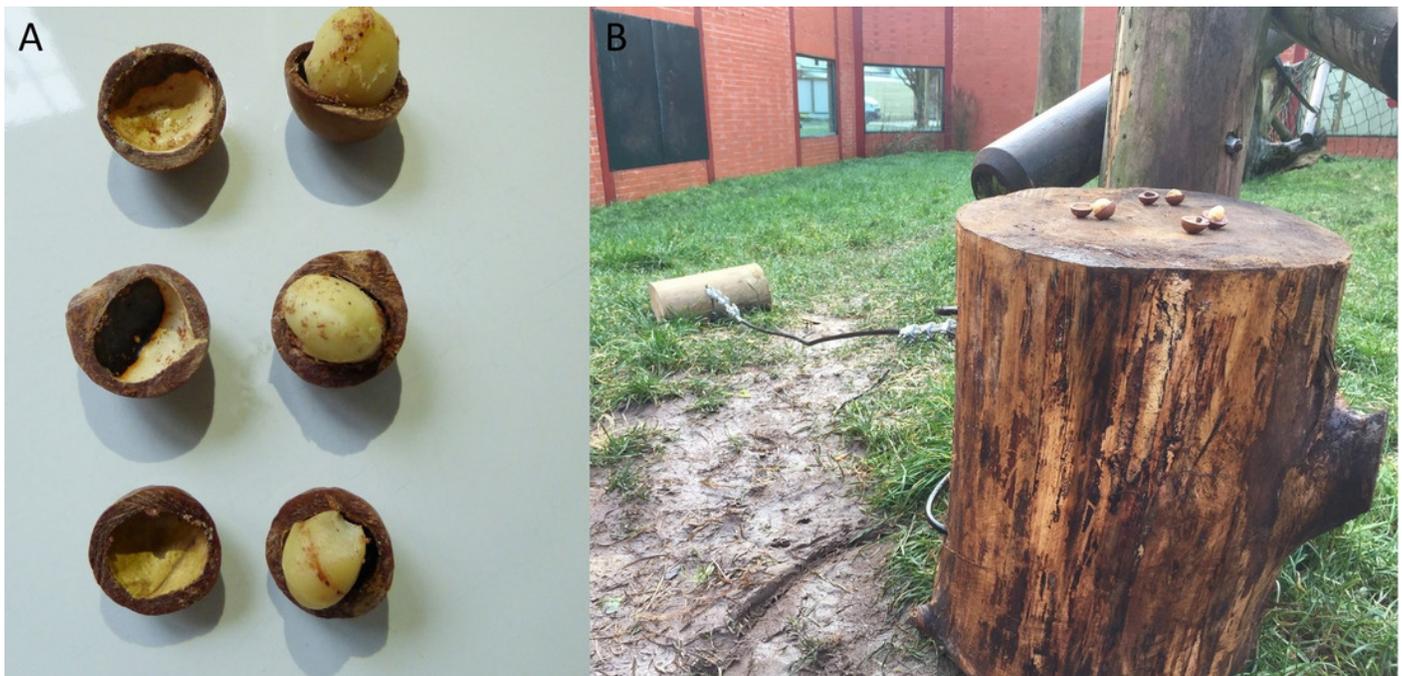

Figure 7

Adult male chimpanzee (C5) cracking a macadamia nut with his teeth, then eating the kernel.

(A) C5 biting the nut in an attempt to break it; (B) C5 consuming the kernel from the now broken shell

Figure 8

Experimental set up for “Ghost” condition in “Eden”.

Note, subjects had access to the entirety of this enclosure throughout these trials including the outdoor enclosure.

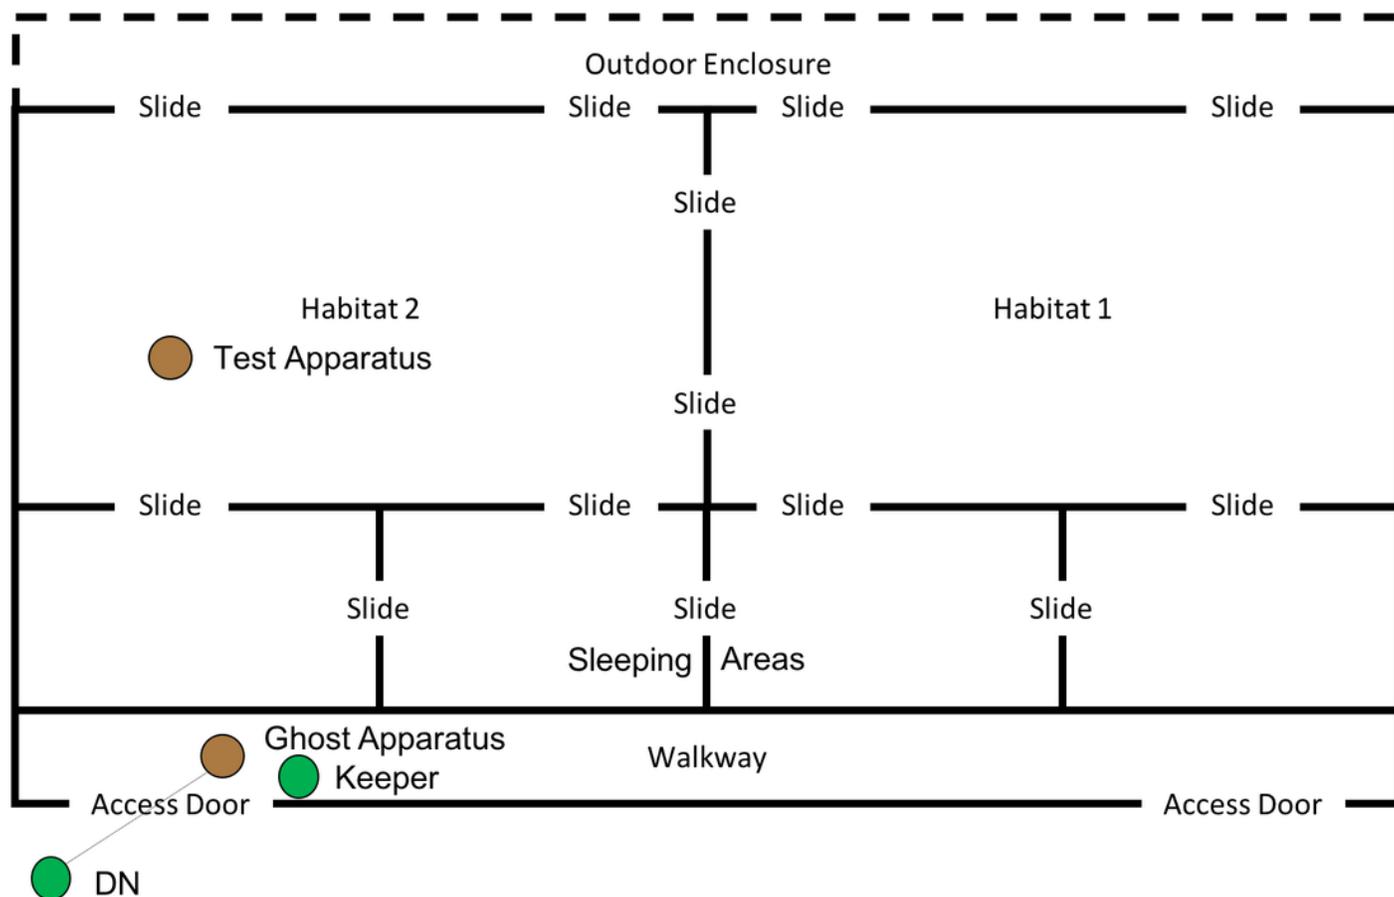

Figure 9

Experimental set up of “Ghost Condition” apparatus.

Note, the hammer is suspended by fishing line, and a single nut is in the centre of the anvil.

Figure 10

DN performing full nut-cracking action demonstrations

(A) subjects' attention was gained by calling their given name; (B) hammer was to eye-level and (C) brought down on the nut as many times as required until it cracked; (D) the cracked nut (both shell and kernel) are provided to the target subject by a keeper. Subject in this demonstration was the female (C9) to the left of DN - holding onto the mesh in panels A-C; keeper rolled the nut to C9 in panel D (hand feeding, even by keepers, is not permitted at the testing institution).
