Traditionally, emotion recognition research has primarily used pictures and videos while audio test materials have received less attention and are not always readily available. Particularly for testing vocal emotion recognition in hearing-impaired listeners, the audio quality of assessment materials may be crucial. Here, we present a vocal emotion recognition test with non-language specific pseudospeech productions of multiple speakers expressing three core emotions (happy, angry, and sad): the EmoHI test. Recorded with high sound quality, the test is suitable to use with populations of children and adults with normal or impaired hearing, and across different languages. In the present study, we obtained normative data for vocal emotion recognition development in normal-hearing school-age (4-12 years) children using the EmoHI test. In addition, we tested Dutch and English children to investigate cross-language effects. Our results show that children's emotion recognition accuracy scores improved significantly with age from the youngest group tested on (mean accuracy 4-6 years: 48.9%), but children's performance did not reach adult-like values (mean accuracy adults: 94.1%) even for the oldest age group tested (mean accuracy 10-12 years: 81.1%). Furthermore, the effect of age on children's development did not differ across languages. The strong but slow development in children's ability to recognize vocal emotions emphasizes the role of auditory experience in forming robust representations of vocal emotions. The wide range of age-related performances that are captured and the lack of significant differences across the tested languages affirm the usability and versatility of the EmoHI test.

ABSTRACT

Traditionally, emotion recognition research has primarily used pictures and videos while audio test materials have received less attention and are not always readily available. Particularly for testing vocal emotion recognition in hearing-impaired listeners, the audio quality of assessment materials may be crucial. Here, we present a vocal emotion recognition test with non-language specific pseudospeech productions of multiple speakers expressing three core emotions (happy, angry, and sad): the EmoHI test. Recorded with high sound quality, the test is suitable to use with populations of children and adults with normal or impaired hearing, and across different languages. In the present study, we obtained normative data for vocal emotion recognition development in normal-hearing school-age (4-12 years) children using the EmoHI test. In addition, we tested Dutch and English children to investigate cross-language effects. Our results show that children's emotion recognition accuracy scores improved significantly with age from the youngest group tested on (mean accuracy 4-6 years: 48.9%), but children's performance did not reach adult-like values (mean accuracy adults: 94.1%) even for the oldest age group tested (mean accuracy 10-12 years: 81.1%). Furthermore, the effect of age on children's development did not differ across languages. The strong but slow development in children's ability to recognize vocal emotions emphasizes the role of auditory experience in forming robust representations of vocal emotions. The wide range of age-related performances that are captured and the lack of significant differences across the tested languages affirm the usability and versatility of the EmoHI test.

INTRODUCTION

Children's development of emotion recognition has been studied extensively using visual stimuli, such as pictures or sketches of facial expressions, or audiovisual materials (e.g., Nowicki and Duke, 1994), and particularly with clinical groups, such as autistic children (e.g., Harms et al., 2010). However, not much is known about the development of vocal emotion recognition (Scherer, 1986). Children have been reported to reliably recognize vocal emotions already from the age of 5 years on, but this ability continues to develop to adult-like levels throughout childhood (Tonks et al., 2007; Sauter et al., 2013). Based on earlier research on the development of voice perception (Mann et al., 1979; Nittrouer et al., 1993), children's performance may be lower compared to adults due to differences in their weighting of acoustic cues and a lack of robust representations of auditory categories. For instance, Morton and Trehub (2001) showed that, when acoustic cues and linguistic content contradict the emotion they convey, children mostly rely on linguistic content to judge emotions, whereas adults mostly rely on affective prosody. In addition, children and adults both perform better in facial than vocal emotion recognition tasks (Nowicki and Duke,

47 1994). All of these observations combined indicate that the formation of robust representations for vocal
48 emotions is highly complex and possibly a long-lasting process even in typically developing children.

49 Research with hearing-impaired children has shown that they do not perform as well on vocal emotion
50 recognition compared to their normal-hearing peers (Dyck et al., 2004; Hopyan-Misakyan et al., 2009;
51 Nakata et al., 2012; Chatterjee et al., 2015). Hopyan-Misakyan et al. (2009) showed that children with
52 cochlear implants (CIs) performed as well as their normal-hearing peers on visual emotion recognition but
53 scored significantly lower on vocal emotion recognition. Visual emotion recognition seems to generally
54 develop faster than vocal emotion recognition (Nowicki and Duke, 1994), particularly in hearing-impaired
55 children (Hopyan-Misakyan et al., 2009), which may indicate that visual emotion cues are perceptually
56 more prominent or easier to categorize than vocal emotion cues. A higher reliance on visual emotion
57 cues as compensation for degraded auditory input can be an effective strategy, as emotion recognition
58 in daily life is usually multimodal, but it may also lead to less robust representations of vocal emotions.
59 In addition, Luo et al. (2018) found that CI users' ability to recognize vocal emotions was significantly
60 correlated to their self-reported quality of life, which demonstrates the importance of recognizing vocal
61 emotions in addition to visual emotions. Finally, Nakata et al. (2012) found that children with CIs had
62 difficulties primarily with differentiating happy from angry vocal emotions. This difference may be related
63 to a higher reliance on differences in speaking rate to categorize vocal emotions, as this cue differentiates
64 sad from happy and angry vocal emotions but is similar for the latter two emotions. Therefore, hearing
65 loss also seems to influence the weighting of different acoustic cues, and hence likely also affects the
66 formation of representations of vocal emotions.

67 As most research on the development of emotion recognition has used visual materials such as pictures
68 or videos, good-quality audio materials are scarce. For normal-hearing listeners, the audio quality may
69 only have a small effect on performance, but for testing hearing-impaired populations it may be highly
70 important. Hence, we recorded high sound quality vocal emotion recognition test stimuli produced
71 by multiple speakers with three basic emotions (happy, angry, and sad) that are suitable to use with
72 hearing-impaired children and adults: the EmoHI test. We aimed to investigate how school-age children's
73 ability to recognize vocal emotions develops with age and to obtain normative data for the EmoHI test for
74 future applications, for instance, with clinical populations. In addition, we tested children of two different
75 native languages, namely Dutch and English, to investigate potential cross-language effects.

76 METHODS

77 Participants

78 Fifty-eight Dutch children and 25 English children between the ages of 4 to 12 years, and 15 Dutch adults
79 and 15 English adults participated in the study. All participants were monolingual speakers of Dutch or
80 English and reported no hearing or language disorders. Normal hearing (hearing thresholds at 20 dB HL)
81 was screened with pure-tone audiometry at octave-frequencies between 500 and 4000 Hz. The study was
82 approved by local ethics committees of the participating institutions. A written informed consent form
83 was signed by the parents of children and adult participants before data collection.

84 Stimuli and Apparatus

85 We made recordings of six native Dutch speakers producing two non-language specific pseudospeech
86 sentences using three core emotions (happy, sad, and angry), and a neutral emotion (not used in the current
87 study). All speakers were native monolingual speakers of Dutch without any discernable accent and did
88 not have any speech, language, or hearing disorders. Speakers gave written informed consent for the
89 distribution and sharing of the recorded materials. To keep our stimuli relevant to emotion perception
90 literature, the pseudospeech sentences that we used, *Koun se mina lod belam* [kʌun sə mi:nə: lət be:ləm]
91 and *Nekal ibam soud molen* [ne:kəl ibəm sʌut mo:lən], were taken from the Geneva Multimodal Emotion
92 Portrayal (GEMEP) Corpus by Bänziger and Scherer (2010). Speakers were instructed to produce the
93 sentences in a happy, sad, angry, or neutral manner using emotional scripts that were also used for the
94 GEMEP corpus stimuli (Scherer and Bänziger, 2010). The stimuli were recorded in an anechoic room at
95 a sampling rate of 44.1 kHz. We selected the productions which received the highest accuracy scores of
96 the four highest-rated speakers based on an online survey with Dutch and English adults. Table 1 shows
97 an overview of these four selected speakers' demographic information and voice characteristics. The
98 neutral productions and the productions of the other two speakers were part of the online survey, and are
99 available with the stimulus set, but were not used in the current study to simplify the task for children.

100 Our final set of stimuli consisted of 36 experimental stimuli with three items (combinations of two times
 101 one sentence and one time the other sentence) per emotion and per speaker (3 items x 3 emotions x 4
 102 speakers) and 4 practice stimuli with one item per speaker that were used for the training session.

Speaker	Age	Gender	Height	Average F0	F0 range
T2	36	F	1.68 m	302.23 Hz	200.71 - 437.38 Hz
T3	27	M	1.85 m	166.92 Hz	100.99 - 296.47 Hz
T5	25	F	1.63 m	282.89 Hz	199.49 - 429.38 Hz
T6	24	M	1.75 m	167.76 Hz	87.46 - 285.79 Hz

Table 1. Overview of the speakers' demographic information and voice characteristics.

103 Procedure

104 Children were tested in a quiet room at their home, and adults were tested in a quiet testing room at
 105 the two universities. The present experiment is part of a larger project (PICKA) on voice and speech
 106 perception conducted by the UMCG for which data were collected from the same population of children
 107 and adults in multiple experiments (Nagels et al., in review). The experiment started with a training
 108 session consisting of 4 practice stimuli and was followed by the test session consisting of 36 experimental
 109 stimuli. The total duration of the experiment was approximately 6 to 8 minutes. All items were presented
 110 to participants in a randomized order.

111 The experiment was conducted on a laptop with a touchscreen using a child-friendly interface that
 112 was developed in Matlab (Figure 1). The auditory stimuli were presented via Sennheiser HD 380 Pro
 113 headphones and calibrated to a sound level of 65 dBA. In each trial, participants heard a stimulus and then
 114 had to indicate which emotion was conveyed by clicking on one of three corresponding clowns on the
 115 screen. Visual feedback on the accuracy of responses was provided to motivate participants. Participants
 116 saw confetti falling down the screen after a correct response, and the parrot shaking its head after an
 117 incorrect response. After every two trials, one of the clowns in the back went one step up the ladder until
 118 the experiment was finished to keep children engaged and to give an indication of the progress of the
 119 experiment.

Figure 1. The experimental interface of the EmoHI test.

120 Data analysis

121 Children's accuracy scores were analyzed using the lme4 package (version 1.1.21, Bates et al., 2014)
 122 in R. A mixed effects logistic regression model with a three-way interaction between *language* (Dutch
 123 and English), *emotion* (happy, angry, and sad), and *age* in decimal years, and random intercepts per
 124 participant and per item was computed to determine the effects of language, emotion, and age on
 125 children's ability to recognize vocal emotions. We used backward stepwise selection with ANOVA
 126 Chi-Square tests to select the best fitting model, starting with the full factorial model, in lme4 syntax:
 127 $accuracy \sim language \cdot emotion \cdot age + (1|participant) + (1|item)$, and deleting one fixed factor at a
 128 time based on its significance. In addition, we performed Dunnett's tests on the Dutch and the English
 129 data with *accuracy* as an outcome variable and *age group* as a predictor variable using the DescTools
 130 package (version 0.99.25, Signorell et al., 2016) to investigate at what age Dutch and English children
 131 showed adult-like performance.

132 RESULTS AND DISCUSSION

133 Model comparison showed that the full model with random intercepts per participant and per item was
 134 significantly better than the full model with only random intercepts per participant [$\chi^2(1) = 393, p <$
 135 0.001] or only random intercepts per item [$\chi^2(1) = 51.9, p < 0.001$]. Backward stepwise selection showed
 136 that the best fitting and most parsimonious model was the model with only a fixed effect of *age*, in lme4
 137 syntax: $accuracy \sim age + (1|participant) + (1|item)$. This model did not significantly differ from
 138 the full model [$\chi^2(10) = 12.90, p = 0.23$] or any of the other models while being the most parsimonious.
 139 Figure 2 shows the data of individual participants and the median accuracy scores per age group for the
 140 Dutch and English participants. Children's ability to correctly recognize vocal emotions increased as a
 141 function of age [z-value = 8.91, estimate = 0.30, SE = 0.034, $p < 0.001$]. We did not find any significant
 142 effects of language or emotion on children's accuracy scores. Finally, the results of the Dunnett's tests
 143 showed that the accuracy scores of Dutch children of all tested age groups differed from Dutch adults
 144 [4-6 years difference = -0.47, $p < 0.001$; 6-8 years difference = -0.31, $p < 0.001$; 8-10 years difference =
 145 -0.19, $p < 0.001$; 10-12 years difference = -0.15, $p < 0.001$], and the accuracy scores of English children
 146 of all tested age groups differed from English adults [4-6 years difference = -0.43, $p < 0.001$; 6-8 years
 147 difference = -0.27, $p < 0.001$; 8-10 years difference = -0.20, $p < 0.001$; 10-12 years difference = -0.12,
 148 $p < 0.01$].

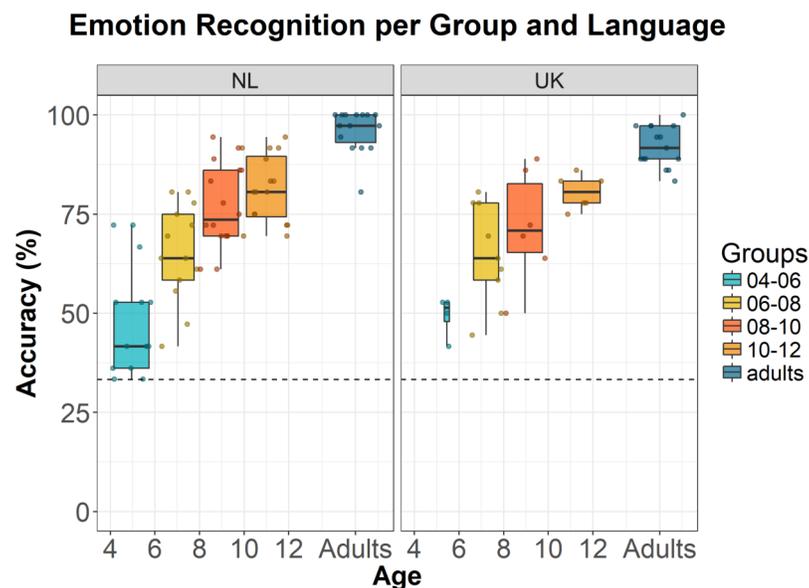

Figure 2. Accuracy scores of participants for emotion recognition per age group and per language (Dutch in the left panel; English in the right panel). The dots show individual data points at participants' decimal age (Netherlands (NL): $N_{children} = 58, N_{adults} = 15$; United Kingdom (UK) : $N_{children} = 25, N_{adults} = 15$). The boxplots show the median per age group, and the lower and upper quartiles. The whiskers indicate the lowest and highest data points within plus or minus 1.5 times the interquartile range.

149 Age effect

150 As shown by our results and the data displayed in Figure 2, children's ability to recognize vocal emotions
 151 improved gradually as a function of age. In addition, we found that, on average, even the oldest age
 152 group of 10- to 12-year-old Dutch and English children did not show adult-like performance yet. The
 153 4-year-old children that were tested performed at or above chance level while adults generally showed
 154 near ceiling level performance, indicating that our test covers a wide range of age-related performances.
 155 Our results are in line with previous findings that children's ability to recognize vocal emotions improves
 156 as a function of age (Tonks et al., 2007; Sauter et al., 2013). It may be that children require more auditory
 157 experience to form robust representations of vocal emotions or rely on different acoustic cues than adults,
 158 as was shown for the development of sensitivity to voice cues (Mann et al., 1979; Nittrouer et al., 1993).

159 It is possible that the visual feedback caused some learning effects, although the correct response was not
160 shown after an error, and learning would pose relatively high demands on auditory working memory, as
161 there were only three items per speaker and per emotion presented in a randomized order.

162 **Language effect**

163 We did not find any cross-language effects between Dutch and English children's development of vocal
164 emotion recognition, even though the materials were produced by Dutch native speakers. Earlier research
165 has demonstrated that although adults are able to recognize vocal emotions across languages, there still
166 seems to be a native language benefit (Van Bezooijen et al., 1983; Scherer et al., 2001). Listeners were
167 better at recognizing vocal emotions that were produced by speakers of their native language than another
168 language. However, these studies used five (Scherer et al., 2001) and nine (Van Bezooijen et al., 1983)
169 different emotions which is likely considerably more complex than differentiating three basic emotions.
170 In addition, the lack of a native language benefit may also be due to the fact that Dutch and English are
171 closely related languages. We are currently collecting data from Turkish children and adults to investigate
172 whether there are any detectable cross-language effects for typologically and phonologically more distinct
173 languages.

174 **Future directions**

175 The results of the current study provide a baseline for the development of vocal emotion recognition
176 for normal-hearing typically developing school-age children using the EmoHI test. Our results show
177 that there is a large but relatively slow development in children's ability to recognize vocal emotions
178 which also brings up the question on which specific acoustic cues children are basing their decisions and
179 how this differs from adults. Future research using machine-learning approaches may be able to further
180 explore such aspects. We are currently collecting data from children with CIs for whom the amount of
181 auditory exposure is reduced due to degraded auditory input. The reduction of auditory exposure may
182 delay or even limit the development of vocal emotion recognition in children with CIs, as some acoustic
183 cues may not be available to hearing-impaired children due to degraded auditory input (Nakata et al.,
184 2012). To conclude, the evident development in children's performance as a function of age and the
185 generalizability across the tested languages show the EmoHI Tests' suitability for future applications with
186 hearing-impaired or other clinical populations of children and adults across different languages.

187 **ACKNOWLEDGMENTS**

188 We are grateful to all children, parents, and students that participated in the study, the speakers of
189 our stimuli, and Basisschool de Brink in Ottersum, Basisschool de Petteflet, and BSO Huis de B in
190 Groningen for their help with recruiting child participants. We would also like to thank Iris van Bommel,
191 Evelien Birza, Paolo Toffanin, Jacqueline Libert, Jemima Phillpot, and Jop Luberti (illustrations) for their
192 contribution to the development of the game interfaces, and Monita Chatterjee for her advice on recording
193 the sound stimuli. This work was funded by the Center for Language Cognition Groningen (CLCG),
194 a VICI Grant from the Netherlands Organization for Scientific Research (NWO) and the Netherlands
195 Organization for Health Research and Development (ZonMw) (Grant No. 918-17-603), the Medical
196 Research Council (Senior Fellowship Grant S002537/1), and framework of the LabEx CeLyA ("Centre
197 Lyonnais d'Acoustique", ANR-10-LABX-0060/ANR-11-IDEX-0007), and the French National Research
198 Agency.
