Auxin response factor(ARF) proteins respond to biological and abiotic stresses and play important roles in regulating plant growth and development. In this study, based on the genome-wide database of sugar beet, 16 BvARF proteins were identified. A detailed investigation into the BvARF family is performed, including analysis of the conserved domains, chromosomal locations, phylogeny, exon-intron structure, conserved motifs, subcellular localization, gene ontology(GO) annotations and expression profiles of BvARF under salt-tolerant condition. The majority of BvARF proteins contain B3 domain, AUX_RESP domain and AUX/IAA domain and a few lacked of AUX/IAA domain. Phylogenetic analysis suggests that the 16 BvARF proteins are clustered into 6 groups. Expression profile analysis shows that most of these BvARF genes in sugar beet under salinity stress were up-regulated or down-regulated to varying degrees and 9 of the BvARF genes changed significantly. They were thought to have a significant response to salinity stress. The current study provides basic information for the BvARF genes and will pave the way for further studies on the roles of BvARF genes in regulating sugar beet's growth, development and responses to salinity stress.

Genome-wide sequence identification and expression analysis of ARF family in sugar beet (*Beta vulgaris L.*) under salinity stresses

They were thought to have a significant response to salinity stress. The current study provides basic information for the BvARF genes and will pave the way for further studies on the roles of BvARF genes in regulating sugar beet's growth, development and responses to salinity stress.

Key words: Sugar beet; ARF; salinity stress; bioinformation

Introduction

ARF are transcription factors that activate or inhibit the expression of auxin-response genes by binding to specific positions in the promoter region of auxin-responsive genes, thereby regulating plant growth and development, including vascular elongation, cell division, apical dominance, flowering, fruit development (Chandler, 2016; Fleming, 2006; Kumar, Tyagi & Sharma, 2011; Li et al., 2016; Ljung, 2013; Su et al., 2014), and responding to abiotic stresses. Most of the ARF proteins consist three conserved domains: the N-terminus DNA binding

¹ Jie Cui, Associate Professor of Harbin Institute of Technology, Mingde Building A602, 92 Xidazhi Street, Nangang District, Harbin, Heilongjiang Province, E-mail:cuijie@hit.edu.cn, Tel:13100888032

24 domain(DBD), the middle region(MR), and the C-terminus domain(PB1). Crystal structures of
25 the DBDs of ARF1 and ARF5 highlight the presence of three different subdomains: a B3
26 subdomain involved in the recognition of the ARF-specific AuxRE DNA motif, a dimerization
27 domain (DD) allowing ARF dimerization, and a Tudor-like ancillary domain (AD) of unknown
28 function which might be involved in an interaction with the DD(Roosjen, Paque & Weijers,
29 2018).The B3 DNA binding domain is capable of binding to a TGTCTC/GAGACA site in the
30 promoter region of the target genes. And ARF proteins homodimerize through their DD, which
31 were also called AUX_RESP domain in ARF, by hydrophobic interactions(Boer et al., 2014).
32 The MR domain has an activation domain (AD) or a repression domain (RD) activity, thereby
33 having an effect of activating or inhibiting transcription. The PB1 domain is the region of
34 homologous dimerization and heterologous dimerization of ARFs or AUX/IAA proteins and
35 ARF (Yu et al., 2014).

36 Since the first *Arabidopsis* ARF gene, ARF1, was cloned and its function investigated
37 (Ulmasov, Hagen & Guilfoyle, 1997), the research on ARF of *Arabidopsis* has entered into the
38 molecular mechanism of regulating plant growth. In recent years, Krogan and others had
39 identified the direct regulation relationship between genes that play a major role in auxin
40 signaling and trafficking (Krogan et al., 2016). Studies by Liu et al. showed that ARF 3 promotes
41 flower meristem formation by inhibiting WUS expression (Liu et al., 2014). Zhao demonstrated
42 that the transcription factor ARF2 modulates the expression of the K⁺ transporter gene HAK5 in
43 *Arabidopsis thaliana*, and found that AtARF2 responds to low potassium stress(Zhao et al.,
44 2016). Zhang studied in AtARF5 and found that it could up-regulate STOMAGEN significantly
45 to regulate stomatal development (Zhang et al., 2014). Report of Li et al. showed that the
46 transcription factors ARF7 and ARF19 are not only important for auxin signaling, but also play
47 critical roles for *Arabidopsis* to respond to ethylene. It may indicated that AtARF7 and AtARF19
48 may be involved in the interaction of the ethylene pathway and the auxin pathway (Li, Dai &
49 Zhao, 2006). With the deepening of research on model plant ARF, the research on ARF of other
50 plants has also started. There are articles on the whole gene analysis of plant ARF such as maize

51 (Xing et al., 2011), sweet orange (Li et al., 2015), rice (Wang et al., 2007), banana (Hu et al.,
52 2015b) and grape (Wan et al., 2014). In these studies, ARF were divided into 6 classes according
53 to their homology to *Arabidopsis thaliana* ARF. Some members of these 6 classes are able to
54 respond to one or more abiotic stresses. It is worth noting that in the study of physic nut ARF
55 (Tang et al., 2018), seven ARFs such as JcARF2, JcARF11, JcARF14 and JcARF15 showed
56 significant changes in expression under salt stress conditions. These JcARFs belong to different
57 5 classes, so it is speculated that ARF may be generally involved in the response of salt stress.
58 And study in tea trees (Xu et al., 2016) have shown that ARF members in roots and shoots of tea
59 plants respond to salt stress, and CsARF6 shows significant up-regulation under different stress
60 conditions, while CsARF2-1 and CsARF11 show significant down-regulation. It is speculated
61 that CsARF members may participate in the regulation of salt tolerance through different ways.

62 Sugar beet is a biennial herb of *Chenopodiaceae*. It is an important sugar-producing crop
63 and widely used in food, sugar production, feed, etc. The yield and quality of sugar beet are
64 susceptible to various biologic and abiotic stresses, especially the soil salinity. In China, the
65 sugar beet production area and the saline land overlap in a large area. Even though sugar beet is a
66 salt-tolerant plant, it is limited in extent. The high salinity of the land not only decreases the
67 suitable planting area of sugar beet but also reduces the yield per unit area. In general, the study
68 of salt-tolerant transcription factors contributes to the cultivation of salt-tolerant related sugar
69 beets and lays the foundation for increasing total sugar beet yield. ARF genes participate in
70 responses to abiotic stresses (Qi et al., 2012; Shen et al., 2013), however, there is no genome-
71 wide analysis for BvARF. Dohm et al. constructed the whole genome of sugar beet. The physical
72 map and sequence of the whole genome of sugar beet (Dohm et al., 2012; Dohm et al., 2014)
73 make it possible to study the salt tolerance of sugar beet from the genetic level. Based on the
74 whole genome database of sugar beet, the genome-wide analysis of BvARF was carried out by
75 bioinformatics method, and the ARF related to salt treatment was identified, which provide a
76 basis of breeding salt-tolerant sugar beet varieties.

77 Materials and methods

78 Materials

79 The research materials used in this experiment for salinity stress were "O68" strain, which
80 was the salt-tolerant sugar beet strain selected by the laboratory(Shi et al., 2008). In the sugar
81 beet seedling stage, the sugar beet seeds were first soaked in running water for 12 h and then
82 sown into the wet sponge which was placed in the incubator for 2 days (dark, 24 °C). Sugar beet
83 seedlings were taken out after they germinated and placed in the culture pot at 22±1 °C with 16
84 h/d supplemental lighting, followed by 8h/d darkness, and cultured with clear water until they
85 grow a third pair of true leaves, then they were treated with salinity stress. The salt stress
86 conditions were that the nutrient solution was replaced with a 300 mM NaCl solution for 24
87 hours, the remaining conditions were unchanged, and the control plants were set at the same time
88 without salt treatment. After the stress treatment, leaves and roots were collected. And they were
89 wrapped in tin foil, quickly placed in liquid nitrogen for precooling. The frozen samples were
90 uniformly stored in the ultra-low temperature refrigerator (-80°C).

91 BvARF identification in sugar beet

92 The whole genome data of sugar beet was published by Max Planck Institute for Molecular
93 Genetics in 2014 (<http://bvseq.molgen.mpg.de/index.shtml>). And the assembly RefBeet-1.1 of
94 KWS2320 was downloaded for bioinformation research. It includes functional annotation,
95 genome sequence, transcript sequences, and protein sequences etc. ARF proteins conserved
96 domain (PF06507) on Pfam were used as a seed sequence to search the whole genome data, and
97 e-value<1e⁻⁵ was set on HMMER (<http://www.hmmmer.org/>). Pfam online tool performed a
98 conserved domain analysis of candidate BvARF protein sequences (Finn et al., 2016), screening
99 protein sequences containing the B3 domain (PF02362), AUX_RESP domain (PF06507) and
100 AUX/IAA (PF02309) domains to remove redundant proteins, and remainders were considered to
101 be BvARF proteins. DNAMAN7.0 was used for multiple sequences alignment of the full-length
102 coding sequence of BvARF proteins, and the conserved domains in the BvARF protein

103 sequences were identified by Weblogo2.8.2 (<http://weblogo.berkeley.edu/logo.cgi>).

104 Bioinformatics analysis of BvARF family

105 Molecular weight and isoelectric point of BvARF proteins were predicted by ExPASy
106 (<https://web.expasy.org/protparam/>). MapInspect was used to map the position of the BvARF
107 genes on chromosomes. Exon and intron structures of the BvARF genes were analyzed by GSDS
108 (<http://gsds1.cbi.pku.edu.cn/>) (Hu et al., 2015a). ClustalX was used to carry out a multiple
109 sequence alignment of BvARF proteins(Larkin et al., 2007). A phylogenetic tree of BvARF
110 family and AtARF family and a phylogenetic tree of BvARF family were constructed by the
111 neighbor-joining with bootstrap replicate set to 1000, and the other parameters default. And the
112 protein sequences of AtARF for comparison were provided in Supplemental File 1. BvARF
113 proteins were submitted to MEME (<http://meme-suite.org/tools/meme>) in the order of homology
114 and subjected to motif analysis(Bailey et al., 2006), in which the number of expected motifs was
115 set to 20, and the rest parameters were all default values. Subcellular localization of BvARF
116 proteins was predicted by using CELLO (<http://cello.life.nctu.edu.tw/>). Gene Ontology (GO)
117 categories of genes were obtained from PlantTFDB
118 (<http://plantregmap.cbi.pku.edu.cn/download.php#go-annotation>), and GO level 2 of BvARF
119 genes were visualized with WEGO (<http://wego.genomics.org.cn/>). And the GO annotation
120 numbers of BvARF were provided in Supplemental File 2.

121 Expression analysis of BvARF under salinity stress

122 Total RNA was isolated from the aforementioned sugar beet samples using MiniBEST Plant
123 RNA Extraction Kit (TaKaRa, Japan) and reverse transcribed into cDNA using High Capacity
124 cDNA Reverse Transcription Kit (applied biosystems, USA). The patterns of expression of these
125 genes under normal growth conditions and in response to salinity stresses were analyzed by
126 quantitative real-time PCR (qRT-PCR). Primers for qPCR were designed using Primer 5 and
127 NCBI Primer-BLAST, synthesized by Huada Gene Co., Ltd., and the primer sequences are
128 shown in Tab 1. The ICDH (Isocitrate dehydrogenase) gene was used as an internal control.

129 For quantitative analysis using the CFX96 Real-Time System (BIO-RAD, USA), and iTaq
130 Universal SYBR Green Supermix kit (BIO-RAD, USA) was used with ICDH as the
131 housekeeping gene. The reaction system was 10 μ L, in which the dye was 5 μ L, the ddH₂O was
132 3.4 μ L, the forward primer and reverse primers were each 0.4 μ L, and the cDNA was 0.8 μ L, and
133 each treatment was repeated three times. Data analysis was performed by calculating $2^{-\Delta\Delta T}$, and
134 the relative expression amount of each gene was expressed by mean \pm standard deviation.

135 Results

136 Identification of BvARF family members

137 Seventeen candidate BvARF proteins were obtained by using PF06507 as a seed sequence to
138 perform HMMER alignment in the sugar beet genome database. And the sequences of 17
139 candidate BvARF proteins were analyzed by Pfam for conserved domain, and the proteins
140 containing no specific domains of ARF were removed. A total of 16 BvARF proteins were
141 identified, as shown in Fig 1.

142 It can be seen from the figure that all BvARF have a C-terminal B3 binding domain and an
143 intermediate AUX_RESP domain, while the AUX/IAA domain exists only in 11 BvARF except
144 for opag, okdq, ghtj, jrpi, and eqms.

145 From the comparison results of DNAMAN7.0, the B3 DNA binding domain is highly
146 conserved and occasionally modified. The AUX_RESP domain is not as conserved as B3, the
147 AUX/IAA domain is the least conserved and in short length, as shown in Fig 2.

148 In the 16 BvARF proteins, gcik.t1 and gcik.t2 were both translation products of transcript
149 variants of BvARF gene gcik. And the efdx.t1 and efdx.t2 were both translation products of
150 transcript variants of BvARF gene efdx. Therefore, a total of 14 BvARF gene loci were obtained
151 and indicated by the name in the sugar beet genome-wide database.

152 The 16 BvARF proteins were blastp aligned with the NCBI database and all found to be
153 members of the BvARF family, as shown in Tab 2. No more new BvARF was identified.

154 Descriptions in NCBI suggest that jrpi, opag and zzhs may have isoforms.

155 Analysis of physicochemical properties of BvARF proteins

156 Sequence analysis showed that the average length of the coding region of ARF gene was
157 2390 bp (1734-3429 bp), the average number of amino acids encoding proteins was 796 (577-
158 1142), and the average molecular weight predicted by ExPASy was 88.7 kDa (64060.51-
159 127711.63 Da), the isoelectric point averages 6.13 (5.21-7.9), as shown in Tab 3.

160 Chromosomal localization of BvARF gene

161 The location analysis showed that 11 BvARF genes were distributed in 8 chromosomes
162 except chromosome 3. There are 2 BvARF on chromosomes 1, 8, and 9, and one on
163 chromosomes 2, 4, 5, 6, and 7, as shown in Fig 3. The location information of other three genes
164 hgze, jrpi, orwr is unknown in the database, that may be caused by these BvARF genes were
165 located in the scaffolds which could not be assembled in the chromosomes.

166 Phylogenetic relationships and gene structures analysis of BvARF

167 To survey the evolutionary relationships between BvARF proteins from sugar beet and
168 previously-reported ARF proteins from the dicot *Arabidopsis* we constructed an unrooted
169 phylogenetic tree with 16 BvARF and 23 *Arabidopsis* ARF protein sequences. The results are
170 shown in Fig 4, based on existing descriptions of ARF conserved domains in *Arabidopsis*
171 (Hagen & Guilfoyle, 2002), and all 39 ARF proteins were divided into six categories.

172 The full-length sequence of the 16 BvARF proteins screened by MEGA7 was used to make
173 a rootless tree by the neighbor-joining method, and the bootstrap procedure was tested with 1000
174 bootstrap repetitions. The results are shown in Fig 5, which are also divided into six categories:
175 Class I (AtARF1/2-like), Class II (AtARF3/4-like), Class III (AtARF5-like), Class IV
176 (AtARF7/19-like), Class V (AtARF6/8-like) and Class VI (AtARF10/16/17-like). Four
177 members were assigned to Class I (qzmp, orwr, kddw and yzaj) 2 to Class II (opag and efdx),
178 Class III only contains hgze, 2 to Class IV (qfwi and zzhs), 2 to Class V (okdq and gcik), and 3

179 to Class VI (ghtj, jrpi and eqms). The intron/exon structure analysis of the BvARF genes can
180 provide valuable information concerning evolutionary relationships among taxa. Analysis of
181 these sequences revealed that all BvARF genes contained introns in the coding sequence, and the
182 number of exons varied from 3 to 15. In general, most of the BvARF members within a given
183 group possessed a similar exon/intron structure in terms of intron numbers and exon length.

184 Motifs analysis and subcellular localization prediction of BvARF proteins

185 For the motifs analysis of the BvARF proteins, the expected number of motifs was set to 20.
186 The motifs were sorted according to the e-value from small to large, and the protein sequences
187 were ranked according to the reliability of the predicted motifs. The results are shown in Fig 6
188 and Fig 7. Some motifs were common to all BvARF proteins, such as motifs 1, 2, 3, and 5, and
189 some motifs were specific to certain proteins, such as motifs 13, 18, and 20. Comparing the
190 results of the motifs analysis with the conserved domains of the previous Pfam, it was found that
191 the motif 1, 2 constituted the B3 domain, the motif 6, 8, 11, 12 constituted AUX_RESP, and the
192 motif 4, 9, 14 constituted AUX/IAA. Previous studies have shown that ARF activates or inhibits
193 target genes in relation to amino acids in the middle region (Tiwari, 2003; Ulmasov, Hagen &
194 Guilfoyle, 1999), and it is worth noting that phantom 17 has a dense glutamine (Q) composition.
195 It has shown in previous research that when glutamines gather in the middle region of the ARF
196 proteins were generally considered to have activation domain activity (Shen et al., 2015). It plays
197 a transcriptional activation role in the transcriptional regulation of auxin, and further predicts that
198 qfwi, zzhs, okdq, gcik may have transcriptional activation which were all in Class IV and Class
199 V.

200 The subcellular localization prediction of CELLO on BvARF proteins is shown in Tab 4.
201 The results showed that the most of BvARF proteins were only scored in the nucleus, that is,
202 they were all more reliably located in the nucleus. The scores of hgze and jrpi were high in
203 cytoplasm and nucleus. Subcellular localization results indicate that almost all BvARF proteins
204 play a regulatory role in the nucleus.

205 Gene Ontology Annotation

206 To survey the functions of the BvARF, GO annotation was obtained from PlantTFDB to
207 construct GO graphs. As shown in Fig 8, all BvARF (14, 100%) are involved in cell part, cell
208 and organelle. The results also showed that the BvARF were involved in diverse biological
209 processes and predominantly participated in metabolic process, biological regulation, regulation
210 of biological process, cellular process(12, 85.7%), binding(11, 78.6%) and response to
211 stimulus(8, 57.1%). The GO terminologies of BvARF were relatively concentrated.

212 Expression profiles of BvARF genes in sugar beet under normal growth conditions and in
213 response to salinity stress

214 In recent years, it has reported that auxin acts as integral part of plant response to salinity
215 stress. Thus we compare the levels of expression of BvARF in condition with and without salt
216 treatment. Expression patterns of 14 BvARF in leaves and root were analyzed by CFX96 Real-
217 Time System to clarify the roles of BvARF genes in salt tolerance. The results are shown in Fig
218 9 and Fig 10. In the leaves, except for jrpi, yzaj and eqms, other BvARF genes all showed
219 different degrees of up-regulation or down-regulation. Most of them showed a down-regulation,
220 and in which the degree of 6 BvARF were significantly reduced (ghtj, okdq, opag, zzhs and
221 efdx). And a few BvARF genes were up-regulated, with only upward trend of gcik was obvious.
222 In the root, after treatment with salinity stress, except for qfwi, orwr and eqms, other BvARF
223 genes all showed different degrees of up-regulation or down-regulation. Most of the BvARF
224 genes showed an upward trend, and in which 6 BvARF showed an obvious upward trend (hgze,
225 okdq, yzaj, kddw, gcik and efdx). And 5 BvARF genes showed a downward trend, but the degree
226 of down-regulation was not significant (ghtj, qzmp, qfwi, jrpi and eqms).

227 Discussion

228 Sugar beet is mainly distributed in Northwest, Northeast and North China, where the saline-
229 alkali soil area is larger. Therefore, it is particularly important to study the salt tolerance

230 mechanism of sugar beet and cultivate new varieties. Members of the ARF family have been
231 reported to be involved in regulation of plant growth, development and response to abiotic
232 stresses. However, the ARF family members in sugar beet have not been studied previously.
233 Thus in order to shed light on the roles of BvARF genes in response salt stress, we delineated the
234 major structural characteristics and expression profiles of ARF genes in this species.

235 In this study, 16 BvARF proteins were discovered by genome-wide analysis, which were
236 transcribed by 14 BvARF genes. The number of members of the BvARF gene family was far
237 less than which of *Arabidopsis*(23), maize(31), rice(25) and other plants. The lack of clustering
238 in spatial locations indicates that there is less gene duplication in the BvARF gene in the long-
239 term evolution process (Cannon et al., 2004; Tang et al., 2018).

240 The phylogenetic comparison of ARF proteins has been widely used in many species, and
241 these proteins have been widely reported in different species and evolutionary relationships. In
242 this paper, according to the phylogenetic tree analysis, BvARF proteins and AtARF were divided
243 into six categories. Four BvARF proteins with similar gene structures belong to the Class I ARF,
244 whereas 13 AtARFs were assigned to this group. This suggests that the genes of the group may
245 have been either lost from the sugar beet lineage or acquired in the *Arabidopsis* after divergence
246 from the last common ancestor shared by *Arabidopsis* and sugar beet. And *Arabidopsis* I ARF-
247 like is closely related to the development of flower and seedling, suggesting that these four ARF
248 may have similar functions in *beta vulgaris* (Ellis et al., 2005). Three BvARF proteins belong to
249 Class II ARF, and according to the Class II ARF function in *Arabidopsis*, which can affect the
250 dorsal ventrality of lateral organs (Pekker, Alvarez & Eshed, 2005). One BvARF protein belongs
251 to Class III ARF, suggesting that it may play a regulatory role in stomatal development and petal
252 differentiation(Cole et al., 2009). Two BvARF proteins belong to Class IV ARF and may
253 regulate lateral roots (Okushima et al., 2005). Three BvARF proteins belong to Class V and may
254 be involved in the regulation of auxin homeostasis (Tian et al., 2004). Three BvARF proteins
255 belonging to Class VI may regulate the formation of pollen walls (Wang et al., 2017).

256 The localization of all 16 BvARF proteins was predicted in the nucleus, indicating their roles
257 in transcriptional regulation. All 16 BvARF proteins have both a B3 DNA binding domain and
258 an ARF response domain, moreover 5 BvARF proteins lack of a CTD which allows dimerization
259 of the ARF proteins and the Aux/IAA proteins. The percentage of members missing CTD
260 (31.3%) was similar to other species, such as tea trees (26.7%) (Xu, Mao, Chen, Qian, Liu, Hao,
261 Li & Chen, 2016) and tomatoes (28.6%) (Kumar, Tyagi & Sharma, 2011).

262 The exon intron pattern shows the homology between species to some extent. The exon-
263 intron splicing arrangement and intron numbers in the BvARF genes in the sugar beet genome
264 were similar to other plants. It is worth noting that BvARF genes in Class VI is consistent with
265 the AtARF genes in Class VI, and the exons are long and are less separated by introns. Motif
266 analysis indicated that the motif 1, 2, 4, 6, 8, 9, 11, 12 and 14 present in most of the BvARF
267 proteins, are the typical motifs present in the auxin response factors protein. Motif 1 and 2 are
268 involved in DNA binding, while 4, 9 and 14 are involved in protein-protein interaction. ARF in a
269 group often has a common motif belonging to their own group. Generally, most of the BvARF
270 genes in one group had similar gene structure and conserved motifs, which further supports their
271 classification as described here and the evolutionary relationships among the groups. Previous
272 studies have shown that the regulation of ARF activation or inhibition is mainly determined by
273 the type of amino acids in the middle region. Belong to Class IV and V, four BvARF (qfwi, zzhs,
274 okdq, gcik) have a poly-Q motif in the central region, indicating that they have an activation
275 effect.

276 ARF is a kind of transcription factor that regulates the expression of auxin-responsive genes.
277 The expression of ARF is also affected by biological and abiotic stresses (Hannah, Heyer &
278 Hinch, 2005; Jain & Khurana, 2009; Kang et al., 2018; Yu et al., 2017). Quantitative results of
279 BvARF genes under salt stress allowed us to identify BvARF genes involved in stress response.
280 The results suggested that six of the 14 BvARF genes were induced or inhibited by salt in leaves
281 and six were induced in roots. And some BvARF expressed differently in leaves and roots, such
282 as okdq and efdx, while some showed the same trend, such as gcik. It can be speculated that

283 ARF have played different degrees of regulation on the salt tolerance of sugar beet. Our study
284 provides evidence that BvARF may participate in sugar beet response to salt stress. Further
285 research is needed to determine which mechanism to achieve salt tolerance.

286 Conclusion

287 In this study, a total of 16 BvARF protein were identified, and we analyzed the gene
288 structures, chromosome location, protein conserved domains, phylogeny, proteins motif,
289 subcellular localization and gene ontology consortium etc. by bioinformatics method. And
290 quantitatively comparing the expression of BvARF in leaves and roots under salt stress and
291 normal environment. This paper laid a foundation for further study of the functional
292 characteristics of BvARF, and provided a new idea for breeding salt-tolerant sugar beet varieties.

Figure 3

Chromosomal localization of BvARF genes.

The unit of gene position is Mb Phylogenetic relationships and gene structures analysis of BvARF.

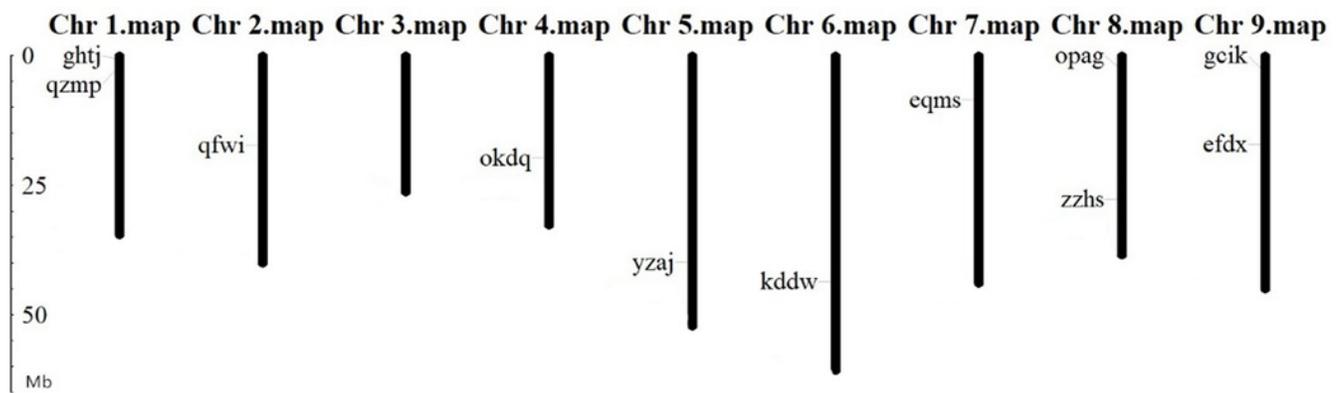

Figure 4

Phylogenetic relationships of BvARF and AtARF proteins.

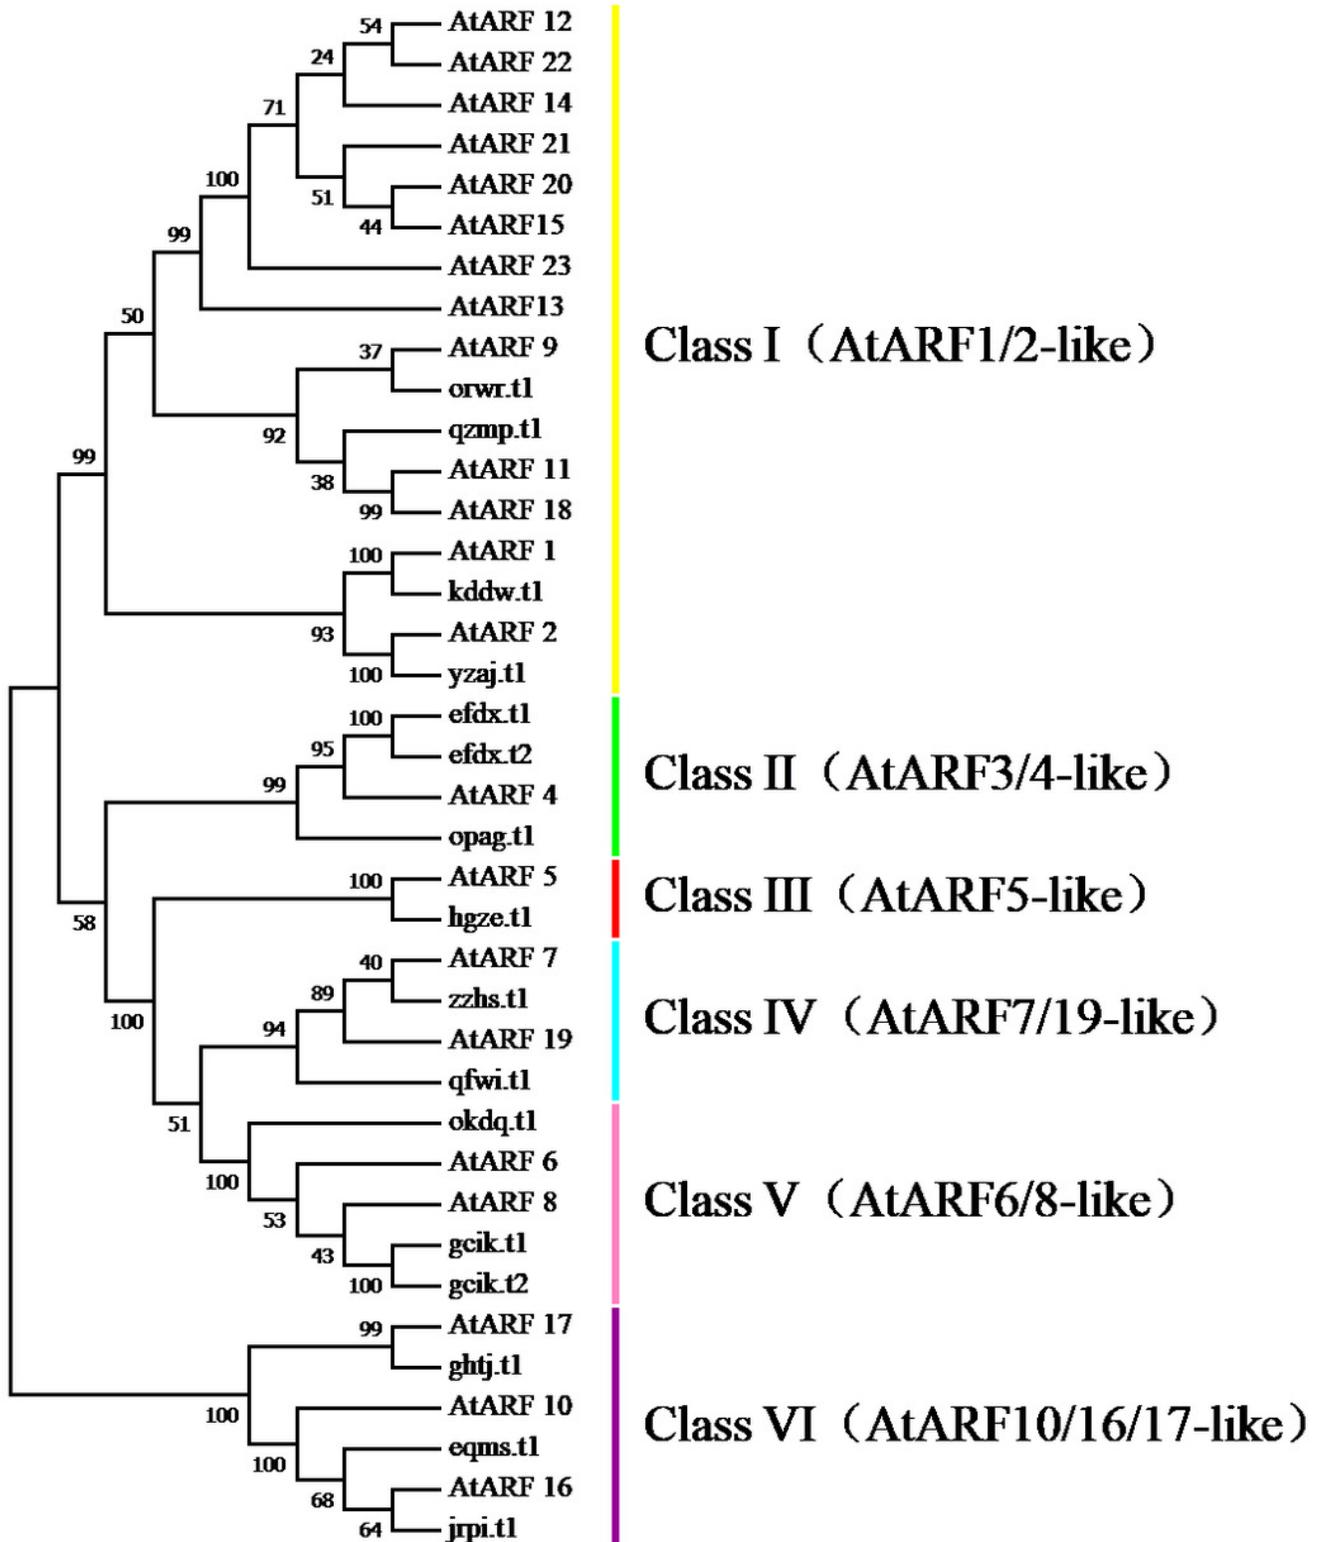

Figure 5

Phylogenetic relationships of BvARF proteins and exon/intron structures of BvARF gene.

Phylogenetic relationships between BvARF proteins. The number on the node represents the confidence value of the branch; the gene Class is represented in a different color on the right side of the rootless tree. Exon/intron structures of the BvARF gene. Exons and introns are represented by yellow box and black lines, respectively.

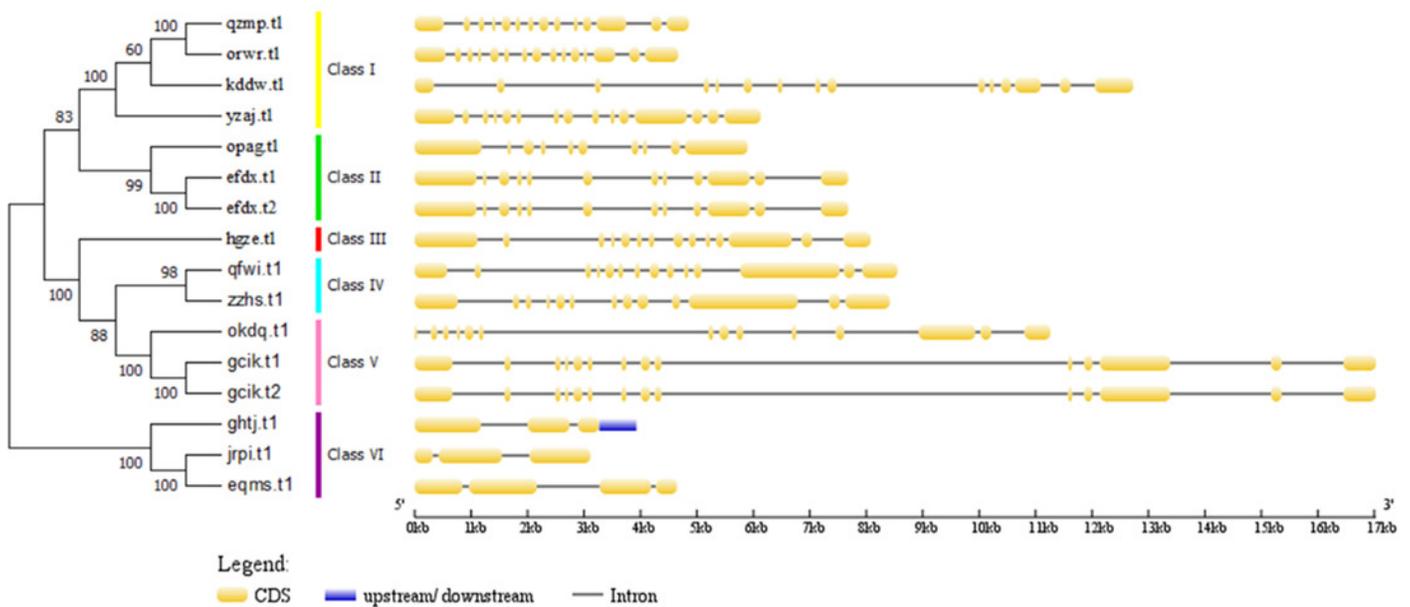

Figure 6

Motifs in BvARF proteins.

The motifs were arranged according to the e-value from small to large, the letters in each motif were amino abbreviation. The size of the letter represented the saliency of the amino acid in the motif. The larger the letter, the higher the saliency, which is, the higher the frequency at which the amino acid appears in the same position in the same motif in different sequences.

Figure 7

Analysis of BvARF proteins motif.

The different color blocks correspond to different motifs. The width of the color block is the length of the motif. The height of the color block represents the saliency of the motifs in the sequence. The higher the saliency, the more able to match the predicted motifs.

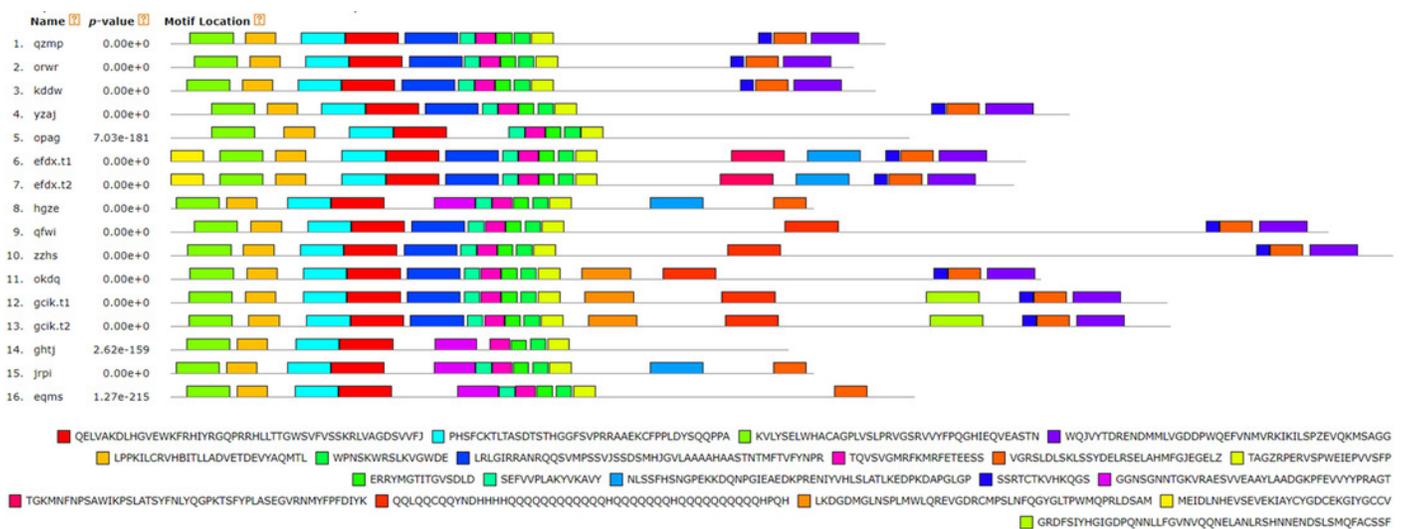

Figure 8

Assignment of GO categories to BvARF genes

Expression profiles of BvARF genes in sugar beet under normal growth conditions and in response to salinity stress.

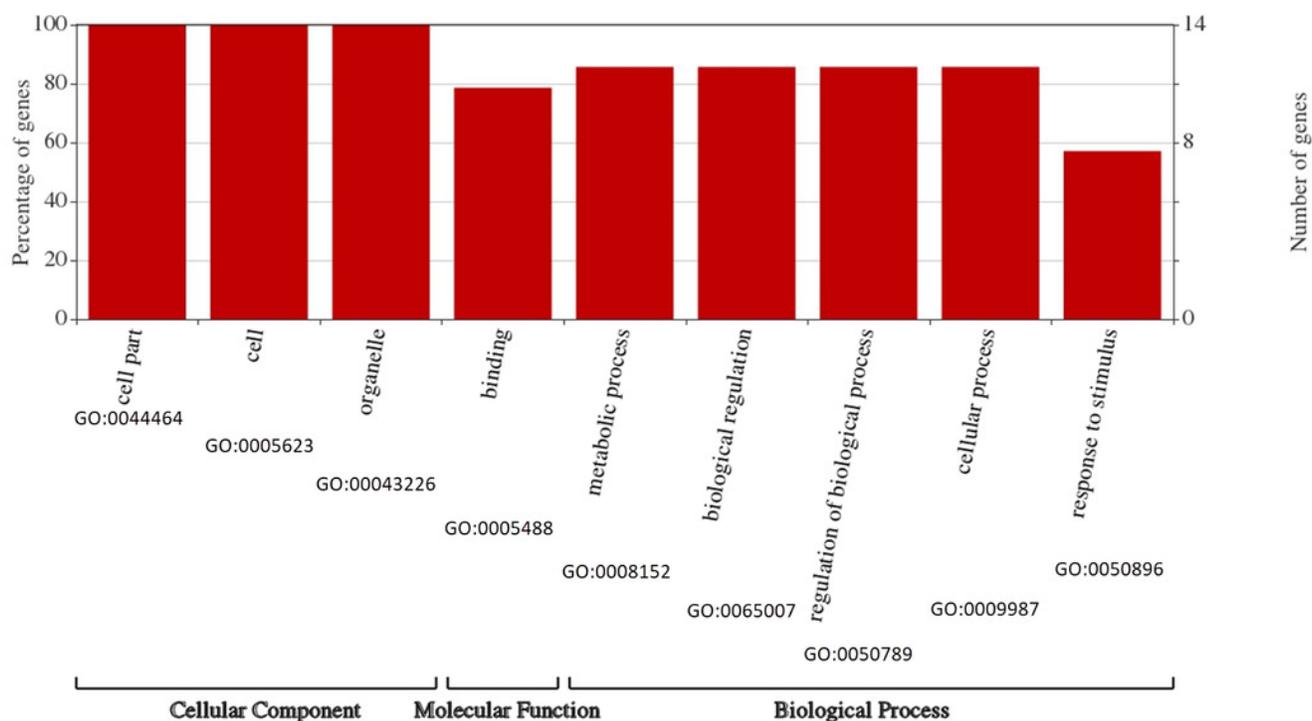

Figure 9

Expression analysis of BARF genes in leaf in response to salinity stress.

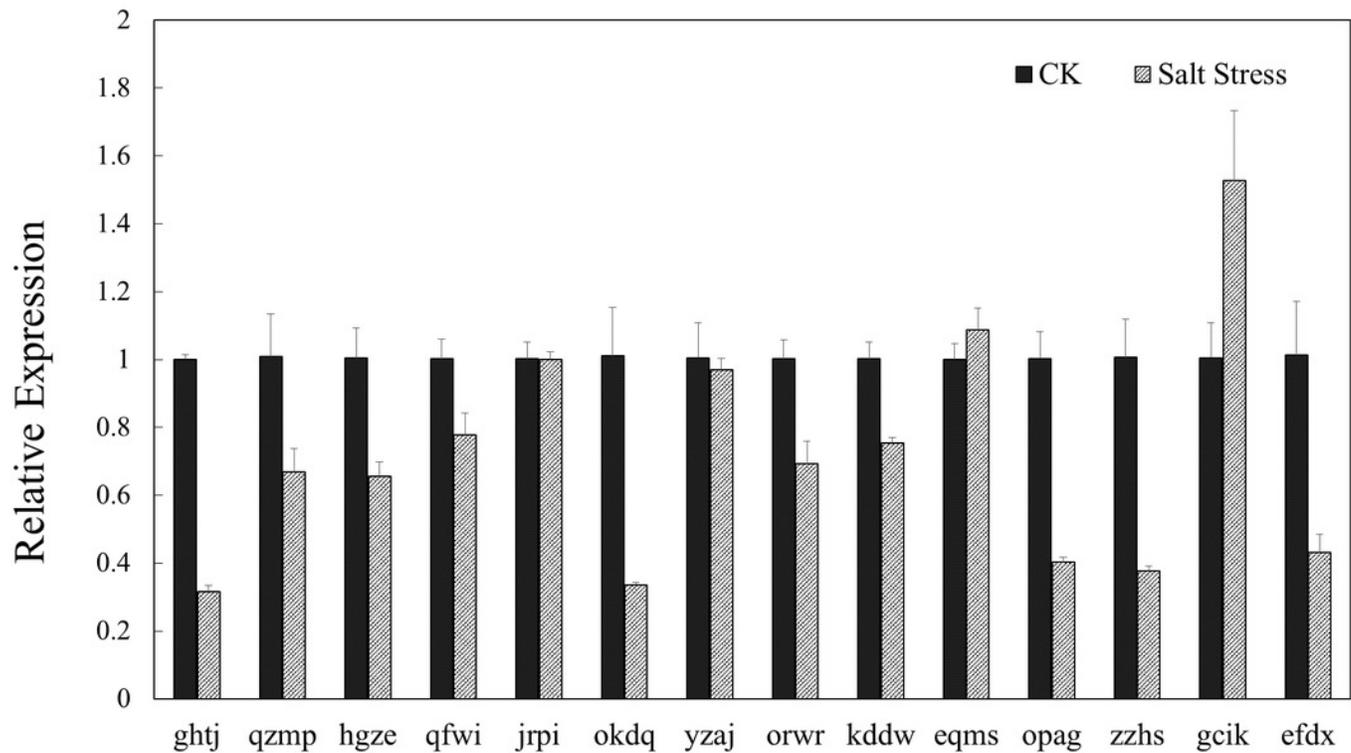

Figure 10

Expression analysis of BvARF genes in root in response to salinity stress.

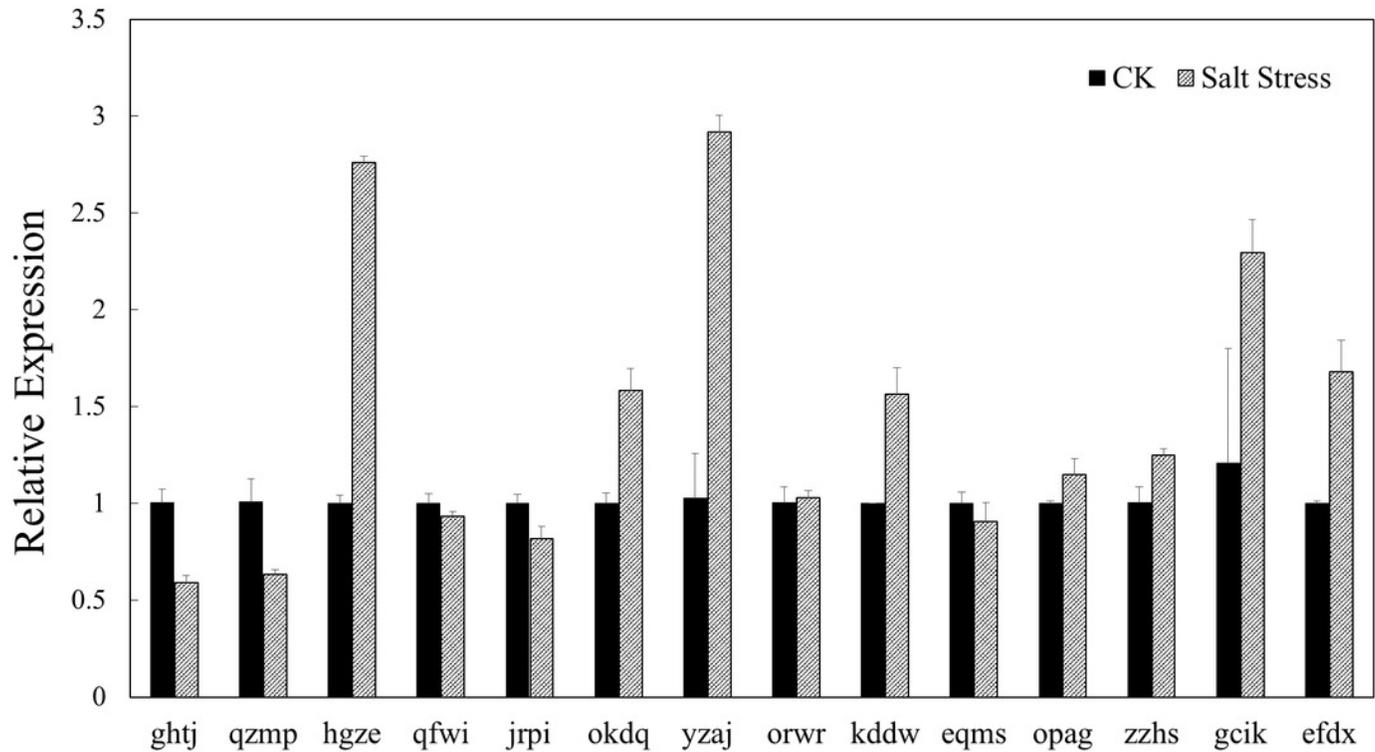

Table 1 (on next page)

primer sequences of ARF

1

Gene	Forward primer(5'-3')	Reverse primer(5'-3')
ghtj	CTGTGTCCACTGACCTAAA	ATCTCTGAGCACTAAGCCC
qzmp	CAAGATTTCTGTAGTCCCG	GTCTCCAGTATTTTGTCCC
