Background. Highly sensitive real-time reverse transcription polymerase chain reaction (qRT-PCR) methods have been developed for the detection of SARS-CoV2 . However, they are costly. Loop-mediated isothermal amplification (LAMP) assay has emerged as a novel alternative isothermal amplification method for the detection of nucleic acid.

Methods. A rapid, sensitive, and specific real-time reverse transcription LAMP (RT-LAMP) assay was developed for SARS-CoV2 detection.

Results. This assay detected 1 copy of SARS-CoV2 RNA in 30 mins. Both the clinical sensitivity and specificity of this assay were 100%. The RT-LAMP showed comparable performance with real-time qRT-PCR. Combining simplicity and cost-effectiveness, this assay is therefore recommended for use in resource limiting settings.

Real-Time Reverse Transcription Loop-Mediated Isothermal Amplification for Rapid Detection of SARS- CoV2

23 Abstract

24 **Background.** Highly sensitive real-time reverse transcription polymerase chain reaction (qRT-
25 PCR) methods have been developed for the detection of SARS-CoV2. However, they are costly.
26 Loop-mediated isothermal amplification (LAMP) assay has emerged as a novel alternative
27 isothermal amplification method for the detection of nucleic acid.

28 **Methods.** A rapid, sensitive, and specific real-time reverse transcription LAMP (RT-LAMP) assay
29 was developed for SARS-CoV2 detection. Forty-seven qRT-PCR positive and 42 qRT-PCR
30 negative nasopharyngeal swabs samples were tested.

31 **Results.** This assay detected one copy of SARS-CoV2 RNA in 30 mins. Both the clinical
32 sensitivity and specificity of this assay were 100%. The RT-LAMP showed comparable
33 performance with real-time qRT-PCR. Combining simplicity and cost-effectiveness, this assay is
34 therefore recommended for use in resource limiting settings.

35

36 Introduction

37 A novel coronavirus, SARS-CoV2, was recently identified causing pneumonia in humans, termed
38 coronavirus disease 2019 (COVID-19). Cases of this new infection were first reported in Wuhan,
39 China in December 2019, and the outbreak spread to more than 155 other countries in a short time
40 [1]. The World Health Organization (WHO) declared the COVID-19 outbreak as a pandemic on
41 11 March 2020. Several real-time reverse transcription polymerase chain reaction (qRT-PCR)
42 methods have been developed and recommended by Centers for Disease Control (CDC) of the
43 United States [2] and WHO [3,4] for detection of SARS-like coronaviruses and specific detection
44 of SARS-CoV2. These methods are highly sensitive and specific but are too expensive to be widely
45 used in many developing countries. Real-time RT-PCR also requires experienced personnel,

maintenance of reagents in cold storage facility, and use of a high-precision thermal cycler. Loop-mediated isothermal amplification (LAMP) has emerged as a novel alternative isothermal amplification method for the detection of nucleic acid [5]. The LAMP assay was reported to take less than one hour to perform at a constant temperature. Since LAMP does not require any major equipment and is simple to perform, it represents an ideal diagnostic tool for use in areas with limited resources. LAMP assays have been described for the detection of various other infectious agents including dengue viruses [6,7] and malaria parasites [8]. In order to further reduce costs and enable detection by the naked eye, we used hydroxynaphthol blue (HNB) dye for the colorimetric detection of the amplification reaction. To our knowledge, this is the first report of the detection of SARS-CoV2 by real-time reverse transcription LAMP (RT-LAMP) assay with HNB.

Materials & Methods

RT-LAMP assay

Primers were designed using the Primer-Explorer V4 software (Eiken Chemical Co., Ltd., Tokyo, Japan) based on SARS-CoV2 nucleoprotein (GenBank accession no MN988713.1, LC528233.1 and MT123293.1). The sequences of the selected primers were conserved among the SARS-CoV2 sequences (Supplementary Figure 1) that do not share homology with other SARS-like coronavirus and Middle East respiratory syndrome coronavirus (MERS) sequences (Supplementary Figure 2). Reverse transcription LAMP (RT-LAMP) was carried out using Loopamp RNA amplification kit (Eiken Chemical Co., Ltd., Japan). The amplification was carried out in a Loopamp real-time turbidimeter (LA-320; Teramecs, Co., Ltd., Tochigi, Japan) at 65 °C for 30 min with 2X reaction mixture, 5 µL RNA template, and species-specific primers. The primer sequences are listed in

Supplementary Table 1. Endpoint assessment was done by visual inspection following the addition of 1 µl HNB (Sigma, USA) in the master mix; a positive amplification was indicated by a colour change from violet to sky blue (Figure 1).

Analytical sensitivity and specificity

To determine the analytical sensitivity of the SARS-CoV2 RT-LAMP assay, *in vitro* transcript RNAs were prepared using a previously published method [9]. Briefly, target gene fragments were cloned to a pGEM-T vector as described in the manufacturer's protocol (Promega, USA). Following digestion with *SalI* restriction endonuclease (NEB, USA), the plasmids were purified. *In vitro* transcribed RNAs were prepared with RiboMAX™ System (Promega, USA) and digested by deoxyribonuclease (DNase) I as described in the manufacturer's protocol. The product was then purified by phenol-chloroform extraction method. Finally, *in vitro* transcribed RNAs were quantified by UV spectrophotometry. The limit of detection (LOD) was determined using 10-fold serially diluted *in vitro* transcript RNA with known numbers of nucleic acid copies (10 cp/µL, 5 cp/µL, 2 cp/µL, 1 cp/µL and 0.1 cp/µL) and comparing the assay with qRT-PCR. The reactions were carried out in duplicates. One µL of each diluted *in vitro* transcript RNA was used for qRT-PCR and RT-LAMP assay.

The specificity of the RT-LAMP assay was determined by using genomic RNA of coronaviruses (HCoV-OC43 and SARS-CoV), adenovirus, human metapneumovirus, influenza A (A/H1pdm2009 and A/H3) viruses, influenza B virus, parainfluenza virus 3, rhinovirus A, respiratory syncytial virus B and enterovirus D68.

Clinical sensitivity and specificity

Forty-seven qRT-PCR positive and 42 qRT-PCR negative nasopharyngeal swabs samples were randomly chosen, regardless of qRT-PCR threshold cycle value (Ct-value) from a recent COVID-19 outbreak in Malaysia (2020) were collected by Hospital Sungai Buloh, Malaysia. Nasopharyngeal swabs were collected using Dacron swabs made of polyester fiber. The swab was inserted into the nostril and back to the nasopharynx and left in place for a few seconds then slowly withdrawn with a rotating motion. The swab was immediately placed into a sterile vial containing 2 ml of viral transport media. Total RNA was extracted using QIAamp viral RNA Mini kit (Qiagen, Germany) according to the manufacturer's instructions. In brief, 140 μ L of cell lysates were transferred into 1.5 mL tubes containing 560 μ L of Buffer AVL followed by vortex for 15 s. After standing at room temperature for 10 minutes, the collection tube was briefly centrifugated. Then 560 μ L of ethanol (96–100%) was added to the sample, and mixed by vortex for 15 s. The mixture was then transferred to QIAamp Mini column and washed with Buffer AW1 and AW2. A 50 μ L-elution was obtained for each sample. The RNA samples were analysed by qRT-PCR (Figure 2), as previously described [3,4]. Briefly, 5 μ L of extracted RNA were added as template into 20 μ L of the reaction mixture containing 12.5 μ L of $2 \times$ reaction buffer provided with the Superscript III one step RT-PCR system with Platinum Taq Polymerase (Invitrogen, USA), 1 μ L of reverse transcriptase/Taq mixture from the kit, 0.4 μ L of a 50 mM magnesium sulphate solution and 1 μ g of nonacetylated bovine serum albumin. Primer and probe sequences targeted at RdRP and E genes were used. Thermal cycling was performed at 55 °C for 10 min for reverse transcription, followed by 95 °C for 3 min and then 45 cycles of 95 °C for 15 s, 58 °C for 30 s.

Extracted RNA for qRT-PCR were kept in -80°C until further analysis by RT-LAMP. SARS-CoV2 RT-LAMP reactions were run at 65°C for 30 min. Clinical sensitivity was calculated as (number of true positives)/(number of true positives + number of false negatives) and clinical

specificity was calculated as (number of true negatives)/(number of true negatives + number of false positives) comparing to qRT-PCR. Ethical approval for this study was obtained from Medical Research Ethics Committee (MREC) Ministry of Health Malaysia (NMRR-20-535-53855).

Results

The SARS-CoV2 RT-LAMP assay was able to detect one copy per reaction of SARS-CoV2 RNA in 30 mins while the LOD for qRT-PCR was five copies per reaction (Supplementary Table 2). The time taken for amplification did not change with or without the addition of HNB in the master mix (Supplementary Table 2). No cross-reactivity with other respiratory viruses (coronaviruses, adenovirus, human metapneumovirus, influenza A viruses, influenza B virus, parainfluenza virus 3, rhinovirus A, respiratory syncytial virus B and enterovirus D68) was found in either assay (Supplementary Table 2).

The RT-LAMP assay demonstrated a 100% sensitivity as all the 47 RNA samples that were positive by qRT-PCR were tested positive with RT-LAMP. None of the 42 qRT-PCR negative samples were positive for SARS-CoV2 using this assay (Supplementary Figure 3). No false-positive reactions were noted (Supplementary Table 2, Supplementary Figure 4).

Discussion

The COVID-19 RT-LAMP reaction was sensitive enough to detect one copy of RNA per reaction, 5-fold better than real-time PCR. Addition of HNB to the LAMP reaction solution did not affect the time taken for amplification. Several studies have found that LAMP out-performs qRT-PCR for other viral infections [6,10,11], which is consistent with our results.

The analysis showed that the RT-LAMP developed is 100% specific and sensitive for the detection of SARS-CoV2 with no false positives detected. The specificity and sensitivity levels of RT-LAMP are comparable to real-time qRT-PCR methods as reported in other studies [12,13]. Encouragingly, the time required for confirmation of results by the RT-LAMP assay was less than 30 mins, 2.5-fold faster than the time required by real-time PCR. Even including the RNA isolation step, RT-LAMP assay can be completed in less than one hour, which is very short when compared to that for real time qRT-PCR (two to two and a half hours).

Due to its high sensitivity, RT-LAMP is prone to aerosol contamination. LAMP assays can be analysed by running an agarose gel or adding SYBR Green I. As it has an inhibitory effect, SYBR Green I has to be added after completion of the LAMP reaction. Tubes used for RT-LAMP reactions have to be opened for gel electrophoresis for addition of SYBR Green I, which can contaminate the air and subsequent reactions. Therefore, in our study, to avoid contamination, HNB dye was used to enable interpretation of the results by the naked eye, without requiring the tubes to be opened. Addition of HNB to the LAMP reaction solution did not affect amplification efficiency. This approach has been shown to be sensitive and simple for visual detection of turkey coronavirus RNA in tissues and faeces [14].

Conclusion

There are several limitations in this study. First, the LOD of the SARS-CoV2 RT-LAMP assay was not determined using serial dilutions of purified cell culture supernatant of SARS-CoV2 due to the unavailability of BSL3 laboratory. Secondly, although we showed specificity when testing against the most closely-related human coronavirus SARS-CoV, we were unable to obtain RNA from other coronaviruses HCoV-229E, HCoV-NL63, and MERS-CoV for specificity analysis.

These experiments should be included in the future to enhance the stringency of the RT-LAMP assay.

In order to improve the efficiency of the RT-LAMP reaction, parameters such as heating temperature, dNTP concentration, and reaction time can be further optimized. There is a high risk of contamination due to the large amount of LAMP products, which often leads to false-positive results. A typical molecular laboratory should be divided into at least three areas for sample preparation, master mix preparation and product detection. However, this may not be available in resource-limited countries. To avoid contamination, general cleaning practices such as decontaminating all surfaces with 10–15 % sodium hypochlorite solution, followed by 70 % ethanol should be routinely carried out. It is highly recommended to adopt a closed end-point detection method in order to avoid carry-over contamination. On top of that, additional mineral oil inside the reaction tubes can reduce the risk of contamination. Sample processing time and cost can be reduced by using direct pathogen detections without upstream RNA extraction by commercial kits. Nie et al., (2012) [15] demonstrated that direct RT-LAMP assay can detect EV71 in heat-treated nasopharyngeal swab specimens.

Lastly, the sensitivity and specificity of the RT-LAMP assay can only be compared with qRT-PCR as there is no true gold standard for SARS-CoV2 detection. It is possible that either test may have misclassified the true result of some of the samples. It is also important to note that the LAMP primers are highly specific, different primers may be needed for detection of different types of mutations of the target gene in the future.

SARS-CoV-2 can also be detected in other biological samples such as sputum, bronchoalveolar lavage fluid, feces and blood [16]. Future studies are expected to assess the feasibility of RT-LAMP in detection of SARS-CoV2 RNA extracted from these biological samples.

To conclude, an inexpensive, rapid, sensitive, and specific RT-LAMP assay was successfully designed for SARS-CoV2 detection. The simplicity of RT-LAMP combined with rapid turnaround time has shown it to be a valuable and applicable tool for the diagnosis of infectious diseases, particularly in resource-limited countries. In addition, RT-LAMP can be easily adapted to point-of-care diagnosis of COVID-19 as supported by a review written by Nguyen et al., (2020) [17] and a non-peer-reviewed preprint by Zhang et. al., (2020) using seven clinical samples [18]. Early and accurate diagnosis is crucial to identify patients with COVID-19 for prompt institutionalization of infection control and public health measures, and when available, treatment.

Figure 1

Assessment of RT-LAMP results based on hydroxynaphthol blue visualization of color change.

A positive reaction indicated by sky blue colour is seen in tubes 1-2 and the positive control (PC), while a violet colour indicates a negative reaction in tubes 4-5 and the non-template negative control (NC).

Figure 2

qRT-PCR results for SARS-CoV2 detection.

The chart was generated by plotting relative fluorescence (RFU) vs. cycle number, with each colored line representing one sample. Seven positive samples and a positive control (PC) are shown with cycle threshold levels between 18 to 40 cycles.
