Guidance from your Editor

Please submit by **21 May 2020** for the benefit of the authors (and your \$200 publishing discount) .

Structure and Criteria

Please read the 'Structure and Criteria' page for general guidance.

Custom checks

Make sure you include the custom checks shown below, in your review.

Author notes

Have you read the author notes on the [guidance page](#)?

Raw data check

Review the raw data.

Image check

Check that figures and images have not been inappropriately manipulated.

Privacy reminder: If uploading an annotated PDF, remove identifiable information to remain anonymous.

Files

Download and review all files from the [materials page](#).

10 Figure file(s)
2 Table file(s)
1 Raw data file(s)
2 Other file(s)

! Custom checks

DNA data checks

- ! Have you checked the authors [data deposition statement](#)?
- ! Can you access the deposited data?
- ! Has the data been deposited correctly?
- ! Is the deposition information noted in the manuscript?

New species checks

- ! Have you checked our [new species policies](#)?
- ! Do you agree that it is a new species?

Is it correctly described e.g. meets ICZN standard?

For assistance email peer.review@peerj.com

Structure your review

The review form is divided into 5 sections. Please consider these when composing your review:

1. BASIC REPORTING
2. EXPERIMENTAL DESIGN
3. VALIDITY OF THE FINDINGS
4. General comments
5. Confidential notes to the editor

 You can also annotate this PDF and upload it as part of your review

When ready [submit online](#).

Editorial Criteria

Use these criteria points to structure your review. The full detailed editorial criteria is on your [guidance page](#).

BASIC REPORTING

-  Clear, unambiguous, professional English language used throughout.
-  Intro & background to show context. Literature well referenced & relevant.
-  Structure conforms to [PeerJ standards](#), discipline norm, or improved for clarity.
-  Figures are relevant, high quality, well labelled & described.
-  Raw data supplied (see [PeerJ policy](#)).

EXPERIMENTAL DESIGN

-  Original primary research within [Scope of the journal](#).
-  Research question well defined, relevant & meaningful. It is stated how the research fills an identified knowledge gap.
-  Rigorous investigation performed to a high technical & ethical standard.
-  Methods described with sufficient detail & information to replicate.

VALIDITY OF THE FINDINGS

-  Impact and novelty not assessed. Negative/inconclusive results accepted. *Meaningful* replication encouraged where rationale & benefit to literature is clearly stated.
-  All underlying data have been provided; they are robust, statistically sound, & controlled.
-  Speculation is welcome, but should be identified as such.
-  Conclusions are well stated, linked to original research question & limited to supporting results.

Standout reviewing tips

3

The best reviewers use these techniques

Tip

Support criticisms with evidence from the text or from other sources

Example

Smith et al (J of Methodology, 2005, V3, pp 123) have shown that the analysis you use in Lines 241-250 is not the most appropriate for this situation. Please explain why you used this method.

Give specific suggestions on how to improve the manuscript

Your introduction needs more detail. I suggest that you improve the description at lines 57- 86 to provide more justification for your study (specifically, you should expand upon the knowledge gap being filled).

Comment on language and grammar issues

The English language should be improved to ensure that an international audience can clearly understand your text. Some examples where the language could be improved include lines 23, 77, 121, 128 – the current phrasing makes comprehension difficult.

Organize by importance of the issues, and number your points

1. Your most important issue
2. The next most important item
3. ...
4. The least important points

Please provide constructive criticism, and avoid personal opinions

I thank you for providing the raw data, however your supplemental files need more descriptive metadata identifiers to be useful to future readers. Although your results are compelling, the data analysis should be improved in the following ways: AA, BB, CC

Comment on strengths (as well as weaknesses) of the manuscript

I commend the authors for their extensive data set, compiled over many years of detailed fieldwork. In addition, the manuscript is clearly written in professional, unambiguous language. If there is a weakness, it is in the statistical analysis (as I have noted above) which should be improved upon before Acceptance.

Description of two new species of the genus *Heterochelamon* Türkay & Dai, 1997 (Crustacea: Decapoda: Brachyura: Potamidae), from southern China

Abstract

This study describes two new species of freshwater crab of the genus *Heterochelamon* Türkay & Dai, 1997 from southern China, *H. huidongense* from Guangdong Province and *H. jinxiuense* from Guangxi Zhuang Autonomous Region. The two new species can be differentiated from congeners by characters derived from the shape of the epibranchial tooth, external orbital angle, cheliped proportions and structure of the male first gonopod. The present study brings the number of *Heterochelamon* species to seven. We used the mitochondrial 16S rRNA gene for a molecular analysis and the results are consistent with the morphological features that support the recognition of two new taxa.

Introduction

The brachyuran crabs belong to the order Decapoda and currently include more than 7000 living species; it is the most diverse group of extant crustaceans (Ng, Guinot & Davie, 2008). Freshwater crabs originated about 136 million years ago (Tsang et al., 2014). With changes in geography over time, some brachyuran crabs adapted to freshwater, eventually forming more than 1300 species of semi-terrestrial or aquatic freshwater crabs (Cumberlidge & Ng, 2009). The rapid divergent evolution of freshwater crabs may be due to the co-evolution between the male and female external genitalia (Yao et al., 2019).

Freshwater crabs are found in the tropics and subtropics in most parts of the world, occurring in aquatic habitats ranging from clear montane streams to lowland rivers and even in

caves or tree holes (Dai, 1999; Ng, Guinot & Davie, 2008). Southern China, where mountains and rivers are abundant, provides a multitude of habitats for a large number of species and the large numbers of new taxa reported in recent years indicate that research on this group remains in a “discovery” phase (Yeo et al., 2008; Zhu, Naruse & Zhou, 2010; Naruse, Zhu & Zhou, 2013; Huang, Mao & Huang, 2014; Shih & Do, 2014; Huang, Shih & Mao, 2016; Huang, Shih & Ng, 2017; Huang, Ah Yong & Shih, 2017; Ng, 2017; Huang, 2018; Huang, Shih & Ah Yong, 2018; Huang, Wong & Ah Yong, 2018; Wang, Huang & Zou, 2019; Wang, Zhou & Zou, 2019).

Currently, the freshwater crabs distributed in China are represented by 49 genera in the families Potamidae Ortmann, 1896 and Gecarcinucidae Alcock, 1910 (Chu et al., 2018; Chu, Wang & Sun, 2018; Huang, Shih & Ah Yong, 2018; Huang, Huang & Shen, 2020). The potamid genus *Heterochelamon* was established by Türkay & Dai (1997) to accommodate *Potamon* (*Geothelphusa*) *purpureomaculata* Wu, 1934 (type species), theretofore assigned to *Malayapotamon*, and two new species, *H. guangxiense* and *H. yangshuoense*. Naruse, Zhu & Zhou (2013) further described two new species, *H. tessellatum* and *H. castanea*. The five known species exclusively occur in Guangxi Zhuang Autonomous Region (Türkay & Dai, 1997; Naruse, Zhu & Zhou, 2013).

In 2011, we collected specimens of a *Heterochelamon* species from Jinxiu, Guangxi, but the crabs were not identified at the time. It was not until 2018 that our research team identified the specimens as belonging to an undescribed species. In 2019, freshwater crab enthusiast Jia-Ming Tian collected some dark colored freshwater crabs from Huidong, Guangdong. We collected specimens too and identified the crabs to be another new species of the genus *Heterochelamon*. As such, we herein describe two new species of the genus *Heterochelamon*, including one from Guangdong Province, representing the first species of the genus known from outside of Guangxi.

To study the phylogenetic relationships of species within *Heterochelamon*, we used the mitochondrial 16S rRNA gene data of four species from this genus, including the two new species reported in this paper. Molecular data supports the recognition of the two new species and their assignment to *Heterochelamon*.

Material & Methods

Specimens were collected by Song-Bo Wang, Yi-Yang Xu, Jia-Ming Tian and Xi-Jiao Wei; preserved in 95% ethanol and deposited in the Department of Parasitology of the Medical College of Nanchang University, Jiangxi, China (NCU MCP), National Tropical Disease Research Center, Shanghai, China (TDRC). The abbreviations G1 and G2 are used for the male first gonopod and second gonopod, respectively. Carapace width and length are reported in millimeters. The terminology used primarily follows that of Dai (1999), Naruse, Zhu & Zhou (2013) and Davie et al. (2015).

Muscle tissue was extracted from the ambulatory legs and chelipeds, and total genomic DNA was extracted from the tissues using the Omega Tissue Kit following the manufacturer’s protocol. Mitochondrial 16S rRNA gene sequences were obtained by PCR amplification with the primers 1471 (5’-CCTGTTTANCAAAAACAT-3’) and 1472 (5’-

AGATAGAAACCAACCTGG-3') (Shih et al., 2004). The PCR procedure was as follows: 33 cycles of denaturation for 50 s at 94°C, annealing for 40 s at 52°C, and extension for 1 min at 72°C, followed by a final extension for 10 min at 72°C. Sequences were obtained by automated sequencing (ABI3730 automatic sequencer).

Sequences were aligned using MAFFT vers.7.355 (Nakamura et al., 2018) based on the G-INS-I method and the selection of conserved regions with Gblocks 0.91b (Castresana, 2000). GTR+I+G was the best fit model for the sequence evolution of the 16S dataset, as determined with MrModeltest vers.2.2 (Nylander, 2005) and then selected based on the Akaike information criterion (AIC). MrBayes vers.3.2.6 (Ronquist et al., 2012) was used to construct a Bayesian inference (BI) tree. Four Markov chain Monte Carlo (MCMC) chains were run for 2,000,000 generations, with samples stored once every 1000 generations, discarding the first 25% as burn-in. Tracer vers.1.6 (Rambaut et al., 2014) was used to check effective sample size (ESS) values (all of greater than 200). Simultaneously with the BI analysis, we used MEGA vers.X.0 (Kumar et al., 2018) to select the best evolutionary model for maximum likelihood (ML) analysis, which was the HKY+I+G model based on the Bayesian information criterion (BIC). The ML tree was built after 1000 bootstrap replicates by using MEGA vers.X.0 (Kumar et al., 2018).

The electronic version of this article in portable document format will represent a published work according to the International Commission on Zoological Nomenclature (ICZN), and hence the new names contained in the electronic version are effectively published under that Code from the electronic edition alone. This published work and the nomenclatural acts it contains have been registered in ZooBank, the online registration system for the ICZN. The ZooBank LSIDs (Life Science Identifiers) can be resolved and the associated information viewed through any standard web browser by appending the LSID to the prefix <http://zoobank.org/>. Family Potamidae Ortmann, 1896

Heterochelamon Türkay & Dai, 1997

Heterochelamon huidongense n. sp. (Figs. 1-4)

urn:lsid:zoobank.org: act: 0F67FA91-6734-4800-9C03-76668635A1E2

Material examined. Holotype: male (25.8 × 23.1 mm) (NCU MCP 423601), Xinaobei Village (22°55'14.59''N 114°33'51.85''E, 47 m asl.), Baihua Town, Huidong County, Huizhou City, Guangdong Province, coll. Song-Bo Wang, Yi-Yang Xu and Jia-Ming Tian, 6th Jul. 2019.

Paratypes: 3 males (30.0 × 25.8 mm, 26.2 × 23.1 mm, 21.3 × 18.6 mm) (NCU MCP 423602,

TDRC 002005, TDRC 002006) and 2 females (26.1×23.5 mm, 20.6×18.5 mm) (NCU MCP 423603, TDRC 002007), same data as holotype. Others: 5 males (29.6×25.4 mm, 26.4×23.5 mm, 25.1×22.3 mm, 28.4×24.5 mm, 21.3×18.9 mm; NCU MCP 423606, NCU MCP 423607, NCU MCP 423608, NCU MCP 423609, NCU MCP 423610) and 2 females (21.1×19.1 mm, 14.5×12.5 mm; NCU MCP 423612, NCU MCP 423613), same data as holotype.

Comparative material. *Heterochelamon yangshuoense* Türkay & Dai, 1997: Holotype, male, IZCAS CB 05102, Yangshuo County, Guilin City, Guangxi Zhuang Autonomous Region, 8th May 1975. *H. guangxiense* Türkay & Dai, 1993: Holotype, male, IZCAS CB 01336, Guangxi Zhuang Autonomous Region, May 1974. *H. purpureomaculata* Türkay & Dai, 1997: not holotype, male, IZCAS CB, Yao Mountain, Xiuren Town, Lipu County, Guilin City, Guangxi Zhuang Autonomous Region, 1938. *H. tessellatum* Naruse, Zhu & Zhou, 2013: Holotype, male, NCU MCP 2012.0003, Dong Men Zhuang, Shuangluo Village, Sanli Town, Shanglin County, Guangxi Zhuang Autonomous Region, 14th Aug. 2006, Paratypes, 1 male, NCU MCP 2012.0004, 1 female, NCHUZOL 13572, same data as holotype. *H. castanea* Naruse, Zhu & Zhou, 2013: Holotype: male, NCU MCP 2012.0001, Lituan Village, Baiming Town, Liuzhou County, Liuzhou City, Guangxi Zhuang Autonomous Region, Aug. 2006, Paratype: 1 female, NCU MCP 2012. 0002, same data as holotype.

Diagnosis. Carapace subquadrate, dorsal surface generally smooth, regions not clearly demarcated. External orbital angle triangular, sharp; postorbital cristae inconspicuous. Epibranchial tooth very sharp, distinct. Anterolateral margin cristae. Suborbital, pterygostomial regions smooth. Median lobe of epistome posterior margin protruded slightly. Third maxilliped exopod exceeding posterior margin of merus, with long slender flagellum. Chelipeds unequal, cutting edges of finger of larger cheliped with blunt teeth, with narrow gap when fingers closed. Ambulatory legs slender. Male telson triangular, lateral margins slightly concave. Female vulva located at middle of sternite 6. G1 terminal segment flat and medially bent, not tapered distally, apex rounded, reaching pleonal locking tubercle on mid length of sternite 5 but not exceeding sternites 4/5 suture.

Description. Carapace subquadrate, width about 1.1 times as length ($n = 13$), regions not clearly demarcated; dorsal surface convex longitudinally, smooth (Figs. 1A, 3A). External orbital angle triangular, generally sharp, separated from anterolateral margin by U-shaped notch; postorbital cristae inconspicuous, postfrontal lobe slightly convex, separated from each other; cervical groove indistinct; H-shaped gastric groove indiscernible (Figs. 1A and 3A). Epibranchial tooth very sharp, distinct; anterolateral margin cristae, straight, lined 7-8 granules, shorter than posterolateral margin; posterolateral surface equally smooth (Figs. 1A, 3A). Frontal, supra-, infraorbital margins cristate, lined with indistinct granules; suborbital, pterygostomial regions smooth, with a few round granules (Fig. 1B). Epistome posterior margin distinctly cristate, median lobe low, triangular, lateral margins slightly sinuous (Fig. 1B).

Third maxilliped exopod exceeding posterior margin of merus, with long slender flagellum; merus about 1.2 times as broad as long, slightly depressed medially; ischium about 1.4 times as long as broad, with distinct median sulcus (Fig. 2B).

Male **Chelipeds** unequal (Fig. 1A). Merus surface smooth without any pits; carpus with inner angle produced into strong spine, surface sparsely covered with pits (Figs. 1A). Cutting edges of larger cheliped fingers with row of large **round** blunt teeth, with narrow gap when fingers closed (Fig. 2A). Ambulatory legs slender; third legs longest when stretched laterally, fourth ambulatory leg propodus about 1.6 times as long as broad, slightly shorter than dactylus, with scattered thorn-like setae (Fig. 2E).

Male thoracic sternites 2/3 demarcated by distinct suture, sternites 3/4 **fused by shallow groove** (Fig. 2C). Male sterno-pleonal cavity deep, reaching anteriorly to mid-length of thoracic sternite 4; median groove between sternites 7/8 long (Fig. 2E). Male pleon triangular, third somite widest; telson triangular with rounded apex, lateral margin slightly concave (Fig. 2C); somite 6 trapezoidal, margins **slightly** oblique; somites 3–6 gradually decreasing in width, increasing in length in males (Figs. 2D). Female pleon broadly ovate (Fig. 3B); vulva small, ovate, located at middle of sternite 6, opening inwards, posterior margin slightly bulged (Fig. 3C).

G1 slender; terminal segment flat, bent medially, not tapered distally, distal part rounded; exceeding pleonal locking tubercle on mid length of sternite 5, not reaching suture between sternites 4/5 (Figs. 4A–D, 2F). Distinct boundary between terminal segment and subterminal segment, latter length about 2.5 times as former, groove for G2 in ventral surface; G2 basal segment triangular, length about 2.1 times distal segment (Fig. 4).

Etymology. The species is named after the type locality, Huidong County, Huizhou City, Guangdong Province.

Distribution. The new species is known only from **type locality** presently, Huidong County, Huizhou City, Guangdong Province, southern China.

Ecology. **This new species** was collected at three sites along a river using fish cages or by hand (Figs. 5B, 5C). The water of the river is relatively clear, and the water flow is slow. The width of the river is approximately 1–3 meters and the depth is approximately 0.2–0.3 meters. The river bed is mainly sand and soil (Fig. 5E). There are many shrubs and low hills around the river, many households located dozens of meters away from the river and some vegetable gardens along the river (Fig. 5A). At one of the collection points, we also collected specimens of the gecarcinucid *Somanniathelphusa sinensis* H. Milne-Edwards, 1853 (Fig. 5D), which we believe coexists with the new species in the river.

Remarks. Compared to congeners, *Heterochelamon huidongense* n. sp. can easily be separated by its G1 not reaching sternites 4/5 suture **in situ** and terminal segment being medially bent (Figs. 2E and 4A, Table 1) (versus reaching sternites 4/5 suture and straight in congeners, except

H. tessellatum which has G1 that also does not reach the sternites 4/5 suture but is strongly bent proximally), as well as a combination of characters: very sharp epibranchial tooth, triangular external orbital angle, slightly convex anterolateral margins (Fig. 1A), triangular male telson (Fig. 2C), inward opening female vulva (Fig. 3C). For detailed differences between this new species and congeners, see Table 1.

***Heterochelamon jinxiuense* n. sp. (Figs. 5-8)**

urn:lsid:zoobank.org:act:5D34B999-78C7-4522-9F74-E872A34B7462

Material examined. Holotype: 1 male (24.6 × 19.8 mm) (NCU MCP 342001), from Tongfu Village (24°17'10.89"N 115°5'17.28"E, 267 m asl.), Toupai Town, Jinxiu Yao Autonomous County, Laibin City, Guangxi Zhuang Autonomous Region, coll. Xi-Jiao Wei, 8th Jul. 2011. Paratypes: 3 males (20.3 × 15.8 mm, 15.8 × 12.6 mm, 17.8 × 14.8 mm) (NCU MCP 342002, TDRC 002008, TDRC 002009) and 1 female (12.9 × 10.4 mm) (NCU MCP 342003), same data as holotype. Other: 1 male (14.1 × 11.4 mm) (NCU MCP 342006), same data as holotype.

Comparative material. See for *Heterochelamon huidongense* n. sp.

Diagnosis. Carapace trapezoidal, flat, surface very smooth. External orbital angle blunt, postorbital cristae, postfrontal lobe indiscernible. Epibranchial tooth blunt, distinct; anterolateral margin cristae, slightly convex. Suborbital, pterygostomial regions very smooth. Median lobe of epistome posterior margin distinctly protruding. Third maxilliped exopod with long flagellum, ischium longitudinal median sulcus almost indistinct. Chelipeds strongly unequal in male adults, surface smooth, lower cutting edge of major cheliped finger with very large, blunt teeth, with medium gap when fingers closed. Ambulatory legs slender. Thoracic sternites 2/3 demarcated by distinct deep suture, anterior part of sternite 3 convex. Male sterno-pleonal cavity deep, narrow. Male telson triangular, lateral margin straight. Female vulva reaching sternites 5/6 suture. Male G1 terminal segment rod-like, decreasing in diameter, subdistal segment suddenly inwardly bent, reaching sternites 4/5 suture.

Description. Carapace trapezoidal, flat, width about 1.3 times as length (n = 6), regions not clearly demarcated; dorsal surface slightly convex, covered with inconspicuous pits (Figs. 6A, 8A). External orbital angle blunt, separated from anterolateral margin by shallow notch; postorbital cristae inconspicuous, postfrontal lobe indistinct; cervical groove indistinct; H-shaped gastric groove indiscernible (Figs. 6A, 8A). Epibranchial tooth blunt, distinct; anterolateral margin cristae, slightly convex, lined with several granules, shorter than posterolateral margin; posterolateral surface smooth (Figs. 6A, 8A). Frontal and orbital margins cristate, lined with indistinct granules, supra-, infraorbital margins glazed; suborbital, pterygostomial regions very smooth, not covered with granules (Fig. 6B). Epistome posterior margin distinctly cristate, median lobe triangular, distinctly protruding, lateral margins almost straight (Fig. 6B).

Third maxilliped exopod exceeding posterior margin of merus, with slender flagellum; merus about 1.2 times as broad as long, with median depression; ischium about 1.4 times as long as broad, longitudinal median sulcus distinct (Fig. 7B).

Chelipeds strongly unequal in adult males (Fig. 7A). Merus surface smooth without any pits; carpus inner angle forming stout spine, surface not covered with pits (Fig. 1A). Cutting edge of larger cheliped fixed finger with large rounded teeth, movable finger cutting edge lined with several small teeth, with medium gap when fingers closed (Fig. 7A). Ambulatory legs slender; third legs longest, the fourth ambulatory leg propodus about 2.0 times as long as broad, equal to dactylus in length (Figs. 6A, 7F).

Male thoracic sternites 2/3 demarcated by distinct deep suture, anterior part of sternite 3 convex, sternites 3/4 suture discernible as shallow groove, abdominal cavity reaching imaginary line joining posterior third of cheliped coxae (Fig. 7C). Male sterno-pleonal cavity deep, narrow; median longitudinal groove between sternites 7/8 medium-length (Fig. 7E). Male pleon triangular, third somite widest; telson triangular with round apex, lateral margin slightly convex; somite 6 trapezoidal; somites 2-6 gradually decreasing in width (Fig. 7D). Female vulva very small, ovate, reaching sternites 5/6 suture, located at upper of sternite 6 (Fig. 8B).

Male G1 slender; terminal segment rod-like, almost straight, tapered distally; apex sharp, abruptly bent inwards subdistally; reaching beyond pleonal locking tubercle on mid length of sternite 5, to suture between sternites 4/5 (Figs. 7E, 9). Boundary between terminal segment and subterminal segment clear, latter length about 2.4 times as former, groove for G2 in ventral surface, G2 destroyed during dissection (Fig. 9).

Etymology. The species is named after the type locality, Jinxiu Yao Autonomous County, Laibin City, Guangxi Zhuang Autonomous Region.

Distribution. The new species is known only from type locality presently, Jinxiu Yao Autonomous County, Laibin City, Guangxi Zhuang Autonomous Region, southern China.

Ecology. The collection site is a small river running behind Tongfu village. The river is mostly surrounded by dwarf mountains and many kinds of fruit trees. The river is approximately 2 meters in width, the water depth is approximately 0.4 meters, the riverbed mainly consists of sand and gravel and the water quality is good.

Remarks.

Heterochelamon jinxiuense n. sp. can easily be differentiated from its congeners by its distally tapered G1 (Fig. 9, Table 1) (versus widening distally or not tapered distally in congeners), blunt external orbital angle (Fig. 6A, Table 1) (versus triangular or acutely triangular in congeners, except that of *H. guangxiense* which is also blunt), strongly unequal chelipeds in adult males and medium gap when male major chela fingers closed (Fig. 7A, Table 1) (versus strongly unequal in *H. tessellatum*, *H. purpureomanualis* and *H. yangshuoense*, but fingers with very broad and

oblong gap when closed; other species unequal with narrow gap when closed). The detailed differences between this new species and congeners are also presented in Table 1.

The new species was collected in 2011, of which the material consisted of five male (one adult and four immature) and one female. The G2 of the only mature male had been destroyed by the time we examined the specimens. We were also unable to find this species in a subsequent collection trip. As of such, the G2 is not described here.

Phylogenetic analyses

We obtained the mitochondrial 16S rRNA gene molecular data from four species of *Heterochelamon* for the first time. Other sequences used were downloaded from GenBank. To show where these two new species fit within the Asian freshwater crab phylogeny, 60 species of 47 genera in the family Potamidae Ortmann, 1896, were used (Table 1). The trees were constructed via the BI and ML methods and showed a high degree of consistency, and the topological structure was determined from BI with support values from both methods (Fig. 10). The phylogenetic results support the recognition of the two new *Heterochelamon* species, *H. tessellatum* and *H. castanea* cluster with the two new species to form an independent branch in the “China-East Asia Islands” clade (Shih, Yeo & Ng, 2009).

Discussion

The genetic analysis supports the recognition of four species of *Heterochelamon* which can also be differentiated morphologically. These four species form a monophyletic group with relatively high support values. Due to the lack of specimens of the other three species of *Heterochelamon*, we were unable to obtain their molecular data for analysis and therefore unable to determine the phylogenetic relationships of these species with the above four species.

Türkay & Dai (1997) established *Heterochelamon* with *Potamon* (*Geothelphusa*) *pupureomaculalis* Wu, 1934 as a type species. However, the real identity of the specimens examined by Türkay & Dai (1997) is questionable, because their specimens are different from the original description by Wu (1934) in the following particulars. Although we could not examine type material or topotypic material from Luocheng Country, Guangxi Zhuang Autonomous Region: the shape of the external orbital tooth is acutely triangular in Wu (1934) versus triangular in Türkay & Dai (1997), the epibranchial tooth is very sharp in Wu (1934) versus blunt in Türkay & Dai (1997), and the G1 terminal segment has a bent tip in Wu (1934) versus straight terminal segment in Türkay & Dai (1997). These differences are also presented in Table 1. Furthermore, the specimens examined by Türkay & Dai (1997) were said to be collected from Xiushui County, Guangxi. The locality record seems to be incorrect, because Xiushui County is in Jiangxi, not in Guangxi. Dai (1999) corrected the locality of *H. cf. pupureomaculalis* to Xiuren County, Guangxi, and we believe that this is correct locality for it. We concur Naruse, Zhu & Zhou (2013) that the specimens referred to *H. pupureomaculalis* by Türkay & Dai (1997) could actually represent an undescribed species.

With a few exceptions, most Chinese freshwater crab genera have restricted distributional ranges. The geographical distribution pattern of many freshwater crabs is caused by geographical isolation, which is due to the limited dispersal abilities of freshwater crabs and low fertility (Yeo et al., 2008; Ji et al., 2016; Jia et al., 2018). The distribution pattern of freshwater crabs in mainland China is closely related to the regional differentiation of China's natural geographical environment. This genus was reported to be mainly distributed in northern Guangxi (Türkay & Dai, 1997; Naruse, Zhu & Zhou, 2013). However, this paper describes a new species from southern Guangdong, which is not in accord with our previous understanding of the distribution of the genus, suggesting that the genus presents a wider distribution pattern than previously thought. Although widened, the distribution of *Heterochelamon* is still within the Huanan freshwater zoogeographical province, which mainly consists of Guangxi, Guangdong and Hainan (Huang, Ebach & Ahyong, 2020). Within this zoogeographical province, there are relatively few abiotic factors such as high mountains and rivers that may obstruct the dispersal of freshwater crabs. We therefore speculate that there may be other new species of *Heterochelamon* in this zoogeographical province that have not yet been discovered.

Conclusions

This study describes two new species of freshwater potamid crabs, referred to the genus *Heterochelamon*. We obtained sequence data of the mitochondrial 16S rRNA gene from the two new species and two other congeneric species for genetic analysis. The analysis supports the recognition of the two new species and the monophyly of the genus. The known distribution of this genus has been heretofore restricted to northern Guangxi, but our study now shows that the genus also occurs in southern Guangdong.

Acknowledgments

We thank Ya-Nan Zhang, Meng-Jun Zhao and Xin-Nan Jia for their help with the molecular experiments and phylogenetic tree. Thanks also to Chao Huang, who provided the image of figure 5C. We are most grateful to Jia-Ming Tian, who provided us with specimens and led us during our second collection. Finally, we give a special thanks to dear Tomoyuki Komai and other two anonymous reviewers for greatly improving our manuscript.
