

Vorinostat enhances chemosensitivity to arsenic trioxide in K562 cell line

Nainong Li, Xiaoyan Guan, Fang Li, xiaofan li, Yuanzhong Chen

Objective : This study aimed to investigate the chemosensitive augmentation effect and mechanism of HDAC inhibitor Vorinostat (SAHA) in combination with arsenic trioxide (ATO) on proliferation and apoptosis of K562 cells. **Methods :** The CCK-8 assay was used to compare proliferation of the cells. Annexin-V and PI staining by flow cytometry and acridine orange/ethidium bromide stains were used to detect and quantify apoptosis. Western blot was used to detect expression of p21, Akt, pAkt, p210, Acetyl-Histone H3, and Acetyl-Histone H4 proteins. **Results :** SAHA and ATO inhibited proliferation of K562 cells in an additive and time- and dose-dependent manner. SAHA in combination with ATO showed significant apoptosis of K562 cells in comparison to the single drugs alone ($p < 0.01$). Both SAHA and ATO alone and in combination showed lower levels of p210 expression. SAHA and SAHA and ATO combined treatment showed increased levels of Acetyl-Histone H3 and Acetyl-Histone H4 protein expression. SAHA alone showed increased expression of p21, while ATO alone and in combination with SAHA showed no significant change. SAHA and ATO combined therapy showed lower levels of Akt and pAkt protein expression than SAHA or ATO alone. **Conclusion :** SAHA and ATO combined treatment inhibited proliferation, induced apoptosis, and showed a chemosensitive augmentation effect on K562 cells. The mechanism might be associated with increasing histone acetylation levels as well as regulating the Akt signaling pathway.

Vorinostat enhances chemosensitivity to arsenic trioxide in K562 cell line

Running title: combination treatment of SAHA and ATO on K562 cell line

Abstract:

Objective: This study was aimed to investigate the chemosensitive augmentation effect and mechanism of HDAC inhibitor Vorinostat (SAHA) in combination with arsenic trioxide (ATO) on proliferation and apoptosis of K562 cells.

Methods: The CCK-8 assay was used to compare proliferation of the cells. Annexin-V and PI staining by flow cytometry and acridine orange/ethidium bromide stains were used to detect and quantify apoptosis. Western blot was used to detect expression of p21, Akt, pAkt, p210, Acetyl-Histone H3, and Acetyl-Histone H4 proteins.

Results: SAHA and ATO inhibited proliferation of K562 cells in an additive and time- and dose-dependent manner. SAHA in combination with ATO showed significant apoptosis of K562 cells in comparison to the single drugs alone ($p < 0.01$). Both SAHA and ATO alone and in combination showed lower levels of p210 expression. SAHA and SAHA and ATO combined treatment showed increased levels of Acetyl-Histone H3 and Acetyl-Histone H4 protein expression. SAHA alone showed increased expression of p21, while ATO alone and in combination with SAHA showed no significant change. SAHA and ATO combined therapy showed lower levels of Akt and pAkt protein expression than SAHA or ATO alone.

Conclusion: SAHA and ATO combined treatment inhibited proliferation, induced apoptosis, and showed a chemosensitive augmentation effect on K562 cells. The mechanism might be associated with increasing histone acetylation levels as well as regulating the Akt signaling pathway.

Keywords:

histone deacetylase inhibitors; arsenic trioxide; K562 cell; apoptosis.

Introduction:

Histone acetylation and deacetylation comprise one of the common modifications found in epigenetics. Histone acetylation helps transcription factors bind to DNA templates and activates transcription; however, histone deacetylation inhibits transcription.^[1-4] In 2006, the second generation of hydroxamic acids histone deacetylase inhibitor (HDACi) SAHA (suberoylanilide hydroxamic acid, Vorinostat) was approved by the FDA for clinical treatment of relapsed or refractory cutaneous T-cell lymphoma.^[5] Chronic myeloid leukemia (CML) is a malignant clonal disease derived from hematopoietic stem cells, and it manifests itself through characteristic molecular markers: the bcr-abl fusion gene and the expression of p210 bcr-abl fusion protein. Tyrosine kinase inhibitors (TKI) are the first line of treatment for CML. Although TKIs target the bcr-abl gene, they are unable to eradicate the malignant clone completely. Moreover, drug resistance has been observed in clinical applications. To better eradicate the CML clone and overcome the drug resistance, we hypothesized that SAHA augments chemosensitivity when combined with Arsenic trioxide (ATO), another widely used chemoreagent for clinical treatment of hematologic malignancies. Thereby, we investigated the anti-leukemia effect of SAHA combined with ATO on the K562 cell line.

Material and Methods

83

84 1. Reagent and cell lines

85 SAHA was kindly provided by Dr. Defu Zeng (City of Hope National Medical Center, US, 91010).
 86 DMSO was diluted to a concentration of 10 mmol / L. ATO was purchased from Heilongjiang Harbin
 87 Medical University Pharmaceutical Co., Ltd., and diluted to a concentration of 2 mmol / L. Both SAHA
 88 and ATO were stored at -20 °C. RPMI 1640 was purchased from Gibco; fetal bovine serum was
 89 purchased from TBD; penicillin / streptomycin was purchased from Hyclone; an apoptosis detection kit
 90 (Annexin-V-FITC, PI double staining) was purchased from Roche; Protein Extraction reagents were
 91 purchased from Wuhan Boster Biological Co., Ltd.; antibodies against c-abl, p21, Acetyl-Histone H3
 92 and Acetyl-Histone H4, and other proteins were purchased from Cell Signaling Technology. The K562
 93 cell line was preserved and cultured in Fujian Institute of Hematology with a standard protocol as
 94 previously described. ^[6,7]

95

96 2. Proliferation assay

97 A CCK-8 assay was used to detect cell line proliferation. A positive control, negative control and the
 98 drug treated group (SAHA: 0.25,0.5,1,2 μmol / L; ATO: 1,2,4,8 μmol / L) were detected. The assay
 99 was completed in triplicate for each group. Next, 5×10^4 cells / ml were seeded into a 96-well culture
 100 plate to a final volume of 100 μl. After 24, 48, and 72 h of treatment, 10 μl of CCK-8 was added into
 101 each well and incubated for 1-4 h at 37 ° C in a 5% CO₂ incubator. The absorbance at 450 nm was
 102 measured using a microplate reader. The inhibition rate was calculated using the following equation:
 103 Inhibition rate = [(control group - experimental group) / blank group] × 100%. A proliferation curve was
 104 plotted based on the drug concentration and the proliferation inhibition rate. The Q value was
 105 calculated to measure the combined effect of SAHA and ATO. Q was calculated using the following
 106 equation: $Q = E(ab) / (Ea + Eb - Ea \times Eb)$ as previously described. ^[6,7] Generally, Ea and Eb are the
 107 single drug inhibition rates; E(ab) is associated with the inhibition rate of SAHA and ATO. $Q > 1.15$
 108 was considered to be a synergistic effect, $0.85 > Q > 1.15$ an additive effect, and $Q < 0.85$ an
 109 antagonistic effect.

110

111 3. Annexin-V and PI staining

112 Apoptosis was detected by Annexin-V and PI staining. Generally, K562 cells(1×10^6) and the
 113 appropriate drugs were co-incubated for 48 h. Cells were harvested after a single wash with PBS.
 114 Next, binding buffer (100 μ l) was added to resuspending cells. Annexin-V (2 μ l) and PI (2 μ l) were
 115 added, and the cells were incubated at room temperature for 10-15 min in the dark. K562 cell were
 116 detected by flow cytometry. Annexin-V⁻/PI⁻ cells were living cells, and Annexin-V⁺/PI⁻ cells were early
 117 apoptotic cells. Annexin-V⁺/PI⁺ were late apoptotic cells. This experiment was repeated three times.

118

119 4. AO / EB fluorescence staining

120 K562 cells and the drugs were co-incubated as described above. Suspended cells (95 μ l, 5×10^6 /ml)
 121 were mixed with AO / EB (5 μ l). Immediately after mixing, one drop of suspended cells was placed on
 122 a clean glass slide and observed by fluorescence microscopy at an excitation wavelength of 490 nm.
 123 Cells with green fluorescence in the nucleus and cytoplasm were normal cells; cells with yellow-green
 124 fluorescence in the nucleus or cytoplasm were apoptotic cells; cells with red fluorescence in nucleus
 125 were necrotic cells.

126

127 5. Western Blot

128 K562 cells were co-cultured as described above. After the cells were lysed, the supernatant was
 129 collected and quantified. Total protein (40 μ g) was transferred to a PVDF membrane after SDS-PAGE
 130 electrophoresis. After blocking at room temperature for 2 h, the primary antibodies (against p210, p21,
 131 Acetyl-Histone H3, Acetyl-Histone H4, Akt and pAkt) were added and incubated at 4 °C overnight.
 132 After washing, the secondary antibody (horseradish peroxidase-conjugated anti-mouse IgG) was
 133 added and incubated for 2 h. The chemiluminescence reaction was performed. β -actin was used as
 134 an internal control.

135

136 6. Statistical analysis

Statistical analysis was performed with SPSS 11.5. Means were compared by the Dunnett-t test, with $P < 0.05$ considered to be a significant difference.

Results

SAHA in combination with ATO showed an additive effect on the inhibition of proliferation

Compared with the control group, SAHA and ATO inhibited proliferation of K562 cells in a time- and dose-dependent manner. After the cells were treated with SAHA and ATO, cell proliferation was significantly inhibited (Fig. 1). SAHA in combination with ATO showed an additive effect on the inhibition of proliferation (Table 1).

SAHA in combination with ATO showed more apoptosis than the single drugs alone

Annexin-V-FITC/PI double staining flow cytometry can distinguish early apoptotic cells, late apoptotic cells and necrotic cells. In the lower left quadrant are normal cells; in the lower right quadrant are early apoptotic cells; in the upper right quadrant are late apoptotic cells; in the upper-left quadrant are necrotic cells. The results showed that 95% of the cells in the control group were living cells; the single drug apoptosis rates increased with increasing drug concentration. The K562 cells apoptosis rates were $10.85 \pm 0.65\%$, $29.65 \pm 1.75\%$, and $84.00 \pm 0.80\%$, 48 h after treatment with SAHA (2 $\mu\text{mol/L}$), ATO (8 $\mu\text{mol/L}$) and 8 $\mu\text{mol/L}$ ATO combined with 2 $\mu\text{mol/L}$ SAHA, respectively. SAHA in combination with ATO showed significant apoptosis of K562 cells compared to the single drugs alone ($p < 0.01$, Fig. 2A).

The apoptosis results were confirmed by AO/EB staining. In the control group, K562 cells showed uniform cell size and morphology and homogeneous green fluorescence in the nucleus and cytoplasm.

In contrast, 48 h after SAHA and ATO combined treatment, we found differences in cell size and morphology. The nucleus was dense, showing yellow-green fluorescent debris. Additionally, SAHA in combination with ATO showed more apoptosis characteristics than the single drugs alone (Fig. 2B-E).

SAHA in combination with ATO showed pronounced changes in protein expression

Both SAHA and ATO alone and in the combination group showed lower levels of p210 expression and. The SAHA group and the combination group showed increased levels of Acetyl-Histone H3 and Acetyl-Histone H4 protein expression. SAHA alone showed increased levels of p21 WAF1/CIP1 expression, while ATO alone and in the combination group showed no significant changes. The combination group showed lower levels of Akt and pAkt protein expression than SAHA or ATO alone (Fig. 3).

Discussion

There are a variety of HDACIs undergoing clinical trials for the treatment of solid tumors and hematological malignancies, especially for the treatment of cutaneous T-cell lymphoma (CTCL), peripheral T-cell lymphoma, and Hodgkin's lymphoma, which have shown promising results. [8] As a novel HDACI, SAHA was approved by the FDA for the treatment of progressive clinical recurrence of CTCL.

ATO is an important medicine for treating leukemia (particularly for acute promyelocytic leukemia, APL). Additionally, chemotherapy regimens based on ATO are a popular research topic. In recent years, the mechanism and clinical applications of ATO have been reported, with induction of oxidative stress and DNA damage included.[9,10] Our study mainly focused on the Akt signal pathway. Huang

reported that ATRA and arsenic compound-based combination therapy was effective in re-inducing morphological remission in relapsed patients with APL who had previous exposure to ATRA and arsenic compounds, thus producing low molecular remission rates and high risk of secondary relapse. ^[11] Interestingly, we also found chemosensitive augmentation of SAHA in the NB4 cell line (data not shown), which indicates that combined SAHA and ATO therapy could have clinical applications in the treatment of leukemia.

The CCK8 results show that individual treatments with SAHA or ATO inhibited K562 cell proliferation in a time- and dose-dependent manner. The combination treatment showed an additive effect in inhibiting proliferation. Additionally, experimental results showed that at certain combined concentrations of SAHA and ATO, there was a greater level of apoptosis than the single drugs alone, which induced apoptosis over 80%. These results indicated that the combined treatment might have beneficial effects including improved chemotherapeutic effects and minimized side effects.

In this study, both SAHA and the combination group induced increased expression of Acetyl-Histone H3 and Acetyl-Histone H4 when compared to ATO and the control. This outcome indicates that SAHA can significantly increase histone acetylation levels and activate transcription, thereby inducing hematological tumor cell apoptosis. ^[3,4]

p21 is an important cell cycle regulatory protein involved in cell growth, differentiation, aging and death. p21 plays a negative role in the regulation of the cell cycle by acting on CDK1. p21 expression was upregulated after treatment with SAHA compared to ATO and the control, thereby blocking the cell cycle and inducing apoptosis. Interestingly, combination therapy did not induce expression of p21. This mechanism needs to be studied further.

Akt is a serine / threonine protein kinase, which plays a major role in the anti-apoptotic pathway in apoptosis signaling. ^[12] We found that both the SAHA group and ATO group downregulate Akt and

pAkt expression. Compared to the single drug treatment, the combination group downregulated Akt and pAkt expression drastically, indicating that the mechanism may be associated with the regulation of the Akt signaling pathway.

p210 fusion protein is the primary cause of CML pathogenesis and progression. Furthermore, the p210 fusion protein is the source of the abnormal phenotype of chronic phase CML. We found that both the SAHA group and the ATO group downregulate p210 fusion protein expression. Also the combination group showed downregulation of p210 protein. Given the dosage which we applied by proliferation experiments, both SAHA and ATO in the concentration are very effective in downregulating the p210 fusion protein expression. It could be more effective by the combination. Taken together, these results indicated that both SAHA and ATO can induce cell apoptosis and inhibition of cell proliferation by downregulating the characteristic p210 fusion protein in K562 cells. Combining SAHA with ATO also lowered the expression of p210, which resulted in increased apoptosis.

In summary, SAHA and ATO can significantly inhibit the proliferation of K562 cells and induce apoptosis. Combined treatment can enhance apoptosis effects within a certain concentration range. The mechanism may be associated with increased histone acetylation and the regulation of the Akt signaling pathway. This study may provide a new combination chemotherapy regimen for the treatment of CML. Further *in vivo* experiments and animal model should be set up to test the enhanced chemosensitivity effect by combining SAHA and ATO. We also need to observe the side effects by combining SAHA and ATO and prepare data for translational medicine work.
