Have the "mega-journals" reached the limits to growth?

Bo-Christer Björk

A "mega-journal" is a new type of scientific journal that publishes freely accessible articles, which have been peer reviewed for scientific trustworthiness, but leaves it to the readers to decide which articles are of interest and importance to them. In the wake of the phenomenal success of PLOS ONE, several other publishers have recently started mega-journals. This article presents the evolution of mega-journals since 2010 in terms of article publication rates. The fastest growth seems to have ebbed out at around 35,000 annual articles for the 14 journals combined. Acceptance rates are in the range 50-70% and speed of publication 3-5 months. Common features in mega-journals are alternative impact metrics, easy reusability of figures and data, post-publication discussions and portable reviews from other journals.

2 # Have the "Mega-Journals" Reached the Limits to Growth?

5 ## Abstract

7 A "mega-journal" is a new type of scientific journal that publishes freely accessible articles, which
8 have been peer reviewed for scientific trustworthiness, but leaves it to the readers to decide
9 which articles are of interest and importance to them. In the wake of the phenomenal success of
10 PLOS ONE, several other publishers have recently started mega-journals. This article presents
11 the evolution of mega-journals since 2010 in terms of article publication rates. The fastest
12 growth seems to have ebbed out at around 35,000 annual articles for the 14 journals combined.
13 Acceptance rates are in the range 50-70% and speed of publication 3-5 months. Common
14 features in mega-journals are alternative impact metrics, easy reusability of figures and data,
15 post-publication discussions and portable reviews from other journals.

Introduction

The scientific scholarly journal emerged in the 17th century and evolved as an institution into its current form in the mid 20th century. A traditional scientific journal appears with a number of regular issues, the format of the articles is more or less standardized, depending on the subject field, and the way articles are accepted and edited follows peer review routines which most academics become intimately familiar with during their careers, as authors, reviewers and editors. Readers get access to the articles mainly through the subscriptions of their institutions (Ware and Mabe, 2015).

Little has seemingly changed since the advent of the web, except for the delivery medium, which nowadays is predominantly electronic, rather than as paper issues. Like in so many other fields the web is, however, also acting as a "disruptive innovation", providing opportunities for fundamentally reshaping the processes and business models. This has in particular provided the platform for the Open Access movement, first started by academics, but later involving start-up publishing companies. There are currently slightly over 10,000 scholarly Open Access (OA) journals indexed in the Directory of Open Access Journals (DOAJ)[1].

Due to their electronic-only delivery, Open access (OA) journals have been able to experiment with many of the "conventions" of scientific publishing. An obvious one is the restriction to publishing articles in a limited number of regular issues. A second one is the fundamental business model for financing the publishing operations. A third one is the way the peer review works.

With the emergence, around the turn of the millennium, of start-up publishers like BioMedCentral and Public Library of Science (PLOS) the business model of scholarly journal publishing has been reversed. Rather than charging readers publishers charge the authors in order to fund their work, usually by requiring the payment of article process charges (APCs). The most evident benefit for the authors is the global open accessibility. The share of APC charging journals among full Open Access journals has rapidly increased in recent years (Laakso & Björk, 2012), and leading commercial and society publishers are now rapidly founding full OA journals. In addition to pure OA journals over 8,000 subscription journals nowadays also allow a paid OA option in so-called hybrid journals (Björk & Solomon, 2014).

Both issueless publishing and financing operations via APCs have rapidly become the mainstream of open access publishing, but most OA journals still adhere to traditional peer review practices. Articles also look pretty much the same as in traditional subscription based journals.The volume range of scientific journals has traditionally been broad, from small journals in the social sciences and humanities with only a single yearly issue to prestigious biomedical journals appearing as frequently as weekly. In the print format few journals have exceeded 1,000 research articles per year. Before the Internet the microeconomics of paper publishing and selling subscriptions made such journals rare exceptions.

Similarly the scope of journals has varied enormously. Very old publishers such as major scientific societies have tended to publish broad journals congruent with their constituencies (

---

[1] http://doaj.org/, 23.4.2015, 10,469 journals

69 *Journal of the American Medical Society*). And some of the world-leading scientific journals are
70 extremely broad (*Nature*). After the second world war in particular the leading commercial
71 publishers started creating lot of "niche" journals picking up new emerging research themes
72 (*Electronic Commerce Research and Applications*). In the social sciences and humanities journals
73 have sometimes been established for extremely narrow purposes (*Nordic Wittgenstein Review*).
74
75 The early successful electronic only OA journals where usually of the narrow variety, often
76 focusing on phenomena relating to the Internet (*Journal of Medical Internet Research*). When new
77 professional OA publishers emerged, they at first strived to launch journals using the same peer
78 review mechanisms and criteria as traditional ones (*PLOS Biology*). In 2006, the OA publisher
79 Public Library of Science launched a new type of journal, which later, due to its success, was been
80 termed a "mega-journal" (the term has also been spelled megajournal or mega journal, in this
81 article mega-journal will be used). *PLOS ONE* incorporates into its business model a number of
82 features which all have been used or at least experimented with before but never in this unique
83 combination. These features have been discussed by a number of authors (Frank, 2012; Binfield
84 2014). The central criterion is a new type of peer review, which only checks that the research
85 methods are scientifically trustworthy, but does no evaluation of the perceived scientific impact
86 or contribution. Provided that the quality of submissions overall is reasonable this leads to lower
87 rejection rate than usual. Together with the broad scope this opens up the opportunity for very
88 big publication volumes.
89
90 Inspired by the phenomenal growth of *PLOS ONE* several reputable publishers have in the past 3-
91 4 years started similar journals, all apparently aiming at annual publication volumes of hundreds
92 if not thousands of articles. Since this is a very recent phenomenon hardly any research has been
93 done about it. The aims of this study were to:
94
95   ▪ Identify currently existing meta-journals
96   ▪ Estimate the number of articles published longitudinally since 2010.
97   ▪ Collect data about the publication charges
98   ▪ Collect data about the acceptance rates
99   ▪ Collect information about the lead times from submission to publication Study other
100   aspects of interest
101

Methods

103 It is unclear to this author who first coined the phrase mega-journal, and hence first discussed
104 what criteria such a journal should fulfill. The Wikipedia article on the topic starts out by saying
105 that "A mega journal is a peer-reviewed academic open access journal designed to be much
106 larger than a traditional journal by exerting low selectivity among accepted articles" (Wikipedia,
107 2015)[2]. This sentence conveys the rationale for the choice of the term mega, indicating a business
108 plan to publish clearly more articles than scholarly journals usually do. The articles by Binfield
109 (2014) and Frank (2012) also include explicit lists of criteria. These sources have been taken into

---

[2] The author wishes to emphazise that he hasn't made any contribution to the Wikipedia article

110   consideration in synthesizing the definition below, used in the study at hand. The three columns
111   indicate which criteria have been mentioned in the three sources above.
112
113   Table 1. Criteria for a mega-journal used in this study
114
115   Binfield and Frank do not use exactly the same terms as above, both for instance talk indirectly
116   about the aim for a big publishing volume in discussing automated workflows, marginal cost for
117   each article below the APC, etc.
118
119   The criteria have been grouped into two levels: primary and secondary. In order to qualify as a
120   mega-journal a journal has to fulfill all the primary criteria. A mega-journal should also fulfill
121   most of the secondary criteria, although they are not mandatory. The APC is in this study
122   considered moderate if it's 1500 USD or below. This is around the average article processing
123   charge currently paid by academics in Western European Countries (Björk & Solomon, 2014) and
124   slightly above the price charge by mega-journal market leader *PLOS ONE*. The publisher prestige
125   criterion is important in an indirect way since it is a very important factor in attracting
126   manuscripts early on and in assuring rapid inclusion in the Web of Science. The impact factor
127   then further accelerates the growth of the journal. This criterion thus helps in identifying strong
128   mega-journal candidates before they have reached high publication volumes and even in the
129   announcement stage. Academic editors means that academics, not professional employed staff
130   act as editors of the individual manuscripts.
131
132   Many mega-journals contain value-adding features, which for the time being mostly are lacking
133   in traditional journals (even in the electronic versions). The reusability of graphics and data is
134   facilitated by the use of Creative Commons licenses, which allows readers to reuse materials
135   without explicitly asking for permission, and technically by having options for downloading
136   images in high resolution for reuse in say presentation slides. Public Library of Science has been
137   a pioneer for what is often termed "Altmetrics" (Priem et al., 2010). This means that the article
138   contains constantly updated data about citations, bookmarks and tweets. Authors (as well as
139   readers) can get also detailed breakdowns of how the article has been downloaded. The
140   possibility for readers to comment on articles provides a sort of open peer review. Also authors
141   can use such facilities for responding.
142
143   An interesting but somewhat controversial practice that several mega-journals are adopting is
144   reuse of reviews from journals, which have rejected the manuscript in question. The terms
145   cascading and portable reviews have been used to describe this (Davis, 2010). Usually the
146   originating journals are more selective journals of the same publisher but in some cases even
147   cross-publisher co-operation has been announced (Clarke, 2013).
148
149   A recent systematic study of publishing delays in different scientific fields (Björk & Solomon
150   2013) found average publishing delays of between 9 and 18 months depending of the field of
151   science. In biomedicine, the area of a majority of mega-journal articles, the average was 9,5
152   months). For OA journals the average was 6 months. In the context of this study rapid publication
153   was defined as less than half a year from the original submission.
154

155 The identification of mega-journals that fulfill the primary criteria and most of the secondary
156 ones, was based on the author's previous knowledge of the OA market, on web searches and on
157 tracking citations to earlier reports about mega-journals. Hence it was a bit like detective work
158 and there is a risk that some recent journals, which could have fitted the criteria, may have been
159 missed.

160 ## Results

161

162 ### List of megajournals

163

164 The basic information about the fourteen identified journals is shown in table 2 below. There is a
165 clear dominance of biomedicine in terms of topics. Several of the journals already have impact
166 factor and other will get them very soon.

167

168 Table 2 The mega-journals studied with basic information about them.

169

170 The list of potential journals was longer but journals were dropped due to a number of reasons.
171 One was that some candidate journals don't explicitly have a review process using the soundness
172 only review criterion. Hindawi's *Scientific World Journal*, which published almost 3,000 articles in
173 2014, was not included for this reason. *ELife* fullfils some of the other criterions, but is aiming to
174 be highly selective in prejudging the impact of an article. Also starting journals like *Modern*
175 *languages Open* (Liverpool University Press), *Open Linguistics* (De Gruyter) and *Science Advances*
176 (AAAS) were not included for the same reason. *Brill Open Humanities* (Brill) and *Heliyon*
177 (Elsevier) would fill the criteria but have not started publishing yet. *Optics Express* has a high
178 publication volume, but a very narrow subject field. Many so-called predatory publishers have
179 journals with extremely broad subject areas aiming at high volumes (Beall, 2013), but they don't
180 fulfill some of the other criteria on the list, in particular since their peer review practices often
181 are highly deficient.

182

183 ### Article volumes

184

185 The year 2010 was picked as the starting point for the collection of article volumes, because this
186 was the year that competitors for *PLOS ONE* appeared on the market. Two methods were used to
187 determine the yearly article numbers. For journals indexed in Scopus a targeted search for
188 articles and reviews was made in that index. This yielded quantitative results for most of the
189 journals with big publication volumes. For the year 2014 some of the bigger journals were also
190 checked from their web sites, since the Scopus figures for the last year did not appear to be
191 complete at the time of analysis. For the rest of the journals their websites were studied to obtain
192 the article numbers. The figures for 2015 are an estimate based on multiplying the articles
193 published in the first quarter of the year by four. The longitudinal development, is shown in table
194 3 below. The order is descending according to the total number of articles. It should be noted that
195 at present only six journals have volumes above 500 articles.

196
197 Table 3 Development of article volumes in mega-journals 2010-2015. The figures for 2015 are
198 the articles published in the first quarter of the year multiplied by four.
199

200 These statistics seem to indicate that the total output of the mega-journals reached a plateau in
201 2013 after which *PLOS* has started to los market share, in particular to Scientific Reports.

202

Publications charges (APCs)

204 The APCs of the journals studied varied in the range 195 - 1950 USD, with several journals
205 situated close to the 1350 USD charged by *PLOS ONE*. The average was 1300 USD. This level can
206 be compared to a global average for OA journals of around 900 USD (Solomon & Björk, 2012),
207 charges of 2500-5000 USD in top-ranking OA journals and the general APC level of 3000 USD in
208 hybrid OA journals (Björk, 2012).
209

210 Most of the mega-journals have announced a price and kept it unchanged. A notable exception *is*
211 *SAGE Open*, which quite dramatically lowered its APC from the initial 695 to 99 USD in 2013. The
212 reason given for this was that an author survey (Research Information, 2013) revealed that most
213 authors who are in the social sciences and humanities had to pay the APC out of their own pocket
214 (currently the APC of *Sage Open* is 195 USD).
215

216 *PeerJ* offers a membership model, where the author pays a one-time fee and can publish as many
217 articles as they wish. The fee varies according to have many articles per year are allowed, and
218 varies between 99 for one article per year and 299 USD for an unlimited number. Every co-
219 author needs, however, to be a member. The de facto APC totally paid per article is difficult to
220 calculate because it also depends on the number of repeat authors. Davis (2014) in an analysis of
221 600 articles published in the journal found a median number of four authors per article, which
222 would indicate an average per article cost of 400 USD. This would be a probably upper limit to
223 the long run average APC.

Acceptance rates

225 The only way to obtain information about the acceptance rates for individual journals is if the
226 publisher in question has made this information available. Acceptance rate data could be found
227 for the following journals:
228

229 *PLOS ONE*, 69 %[3]
230 *BMJ Open*, 60 %[4]
231 *Scientific Reports*, 55 %[5]
232 *FEBS Bio Open*, 68%, [6]
233 *Biology Open*, 51 %, [7]

---

[4] http://bmjopen.bmj.com/site/about/
[5] http://occamstypewriter.org/trading-knowledge/2012/07/09/megajournals/
[6] http://occamstypewriter.org/trading-knowledge/2012/07/09/megajournals/
[7] http://bio.biologists.org/site/about/about_bio.xhtml

234
235   These acceptance rates can be compared to the acceptance rates of scholarly journals in general.
236   Although some top journals have acceptance rates of only 5-10 %, Sugimoto et al (2013) in a
237   study of around 5000 journals in five broad areas found average acceptance rates of between 30
238   % (business) and 46 % (health). The corresponding acceptance rates for OA journals in these
239   same fields were between 37 % and 57 %.
240
241   What this means is that risk of rejection in a mega-journal is significantly lower than in the
242   average peer-review journal in its field. Authors who are reasonably competent as researchers
243   probably perceive the rejection risk as very low, and also much less prone to the subjective
244   values and possible biases of the reviewers asked also to judge the significance of the results in
245   more selective journals.

246   ## Publishing speed
247   Some mega-journal publishers have made information about acceptance and publishing public
248   on the journal website, in press releases, editorials, conference presentations etc. *Scientific*
249   *Reports* for instance announces a median time of 139 days for February 2015 articles[8]. *BMJ Open*
250   reports a median time to first decision of 46 days in 2013, but there is no info of the full
251   publishing delay[9]. For articles published in December 2014 in *PLOS ONE* it took 123 days from
252   submission to acceptance and 30 days more to final publication (Davis, 2015). *Springer Plus*
253   claims a speed to first decision of less than three months and less than a week from acceptance to
254   publication[10]. For articles published in the first half year of *PeerJ* the median time from
255   submission to final acceptance was 51 days[11].
256
257   Based on the figures above mega-journals seem to have shorter throughput times also compared
258   to OA journals in general, not to mention subscription journals. So-called predatory OA journals
259   seem to be even quicker than mega-journals (Shen & Björk, 2015), but they often lack a proper
260   peer review and lack academic credibility.

261   ## Secondary features
262

263   Table 4 shows the inclusion of the secondary features in the studied journals. In the case of *Brill*
264   *Open Humanities* and *Helyion* it was difficult to check for some of the features since they are not
265   yet publishing articles. It is highly likely that all journals fulfill the publishing speed criterion, but
266   for those were no statistics could be found a "?" has been inserted in the table.
267

268   Table 4. Secondary features in use in the studied mega-journals
269

270   *PeerJ* isn't backed by an established publisher, but on the other hand its founders and
271   management team includes individuals with a proven track record in scholarly publishing.

Discussion

Fourteen mega-journals were identified. In some cases the publishing volumes are still rather small, but given the backing of well-known publishers and the high probability for getting impacts factors in the near future the growth potential is there. The Mega-journal as type of scholarly journals has emerged rapidly, as demonstrated by the growth in publication volumes reported in table 3. Publishers have identified a clear market demand for this type of publication outlet and are offering their services at a price level attracting lots of submissions. A key competitive factor in launching a mega-journal is if the journal can use the publisher's brand to create a high-quality image from the start, hence names like BMJ Open, Springer Plus, SAGE Open. A mega-journal published by a major publisher can also benefit from a ready IT infrastructure for review and manuscript management.

On the other hand the first rapid growth seems to have leveled out and competitors of market leader *PLOS ONE* seem to be capturing an increasing share. At the current level of around just under 40,000 annual articles the output still only represents some 2 % of the yearly global output of scholarly articles, which is around 2 million (Ware & Mabe, 2015). The market share of mega-journals of the APC financed Open Access market is however much bigger. Extrapolating from the figure of 136,000 and growth rate reported in Laakso & Björk (2012) as well as for the figure of 120,000 articles by OASPA member publishers (Redhead ,2014) a conservative estimate for DOAJ registered OA journals would be 200,000 which would mean that the share of mega-journals would be in the order of 15-20 %. The future development of mega-journals could be highly dependant on the growth of APC charging OA journals in general.

Mega-journals have found a place in the scholarly publishing ecosystem where they get a fair share of their manuscripts via rejections from other journals higher up in the ecosystem (usually highly selective journals). Solomon (2014) in his survey of authors in four mega-journals found resubmission rates of between 32 and 62 %, depending on the journal. The use of portable reviews means that in many such cases the authors lose relatively little time in getting published. One important aspect of mega-journals is how they complement the portfolios of major commercial and society publishers consisting of subscription journals, most of which nowadays offer a hybrid OA choice, and niche and more selective Open Access journals. The mega-journals can use the same technical infrastructures as the other journals, and provide an easy way for the publishers to tap into the growing APC market. The rapid launching of mega-journals of by many established publishers indicates that they are seen as commercially viable. Each major publisher can, however, credibly have only one mega-journal in its portfolio, which poses a limit to the viable number of journals with strong publisher branding.

Although mega-journals offer excellent economies of scale, the growth could in the longer run be limited by the availability of motivated unpaid reviewers (Buriak, 2015). Firstly the task is less intellectually challenging than in more selective traditional journals, where the perceived contribution needs to be judged as well. Secondly the major motivation for unpaid reviewers is often to build up their social capital in their networks of colleagues, so that responding diligently to review requests from leading academics in their field, may lead to appointments to editorial boards, associate editors etc. This factor may be less present in many mega-journals, which rely more on the sense of academic duty of potential reviewers.

317
318 Another aspect limiting the growth is the lack of branding for authors publishing in mega-
319 journals. Many experts, promotion committees etc base their evaluations of junior academics
320 primarily on where these have published. In most fields there are well-established pecking
321 orders of top journals, and in addition having a reasonably good impact factor also counts.
322 Academics also tend to spread their articles over a range of journals, where one or even two
323 mega-journal articles can be acceptable, but where numerous ones in the list of publications
324 would be not be good sign.

Table 1

Criteria for a mega-journal used in this study

Criteria/mentioned in sources	Wikipedia	Binfield	Frank
Primary criteria			
Big publishing volume or aiming for it	√	√	√
Peer review of scientific soundness only	√	√	√
Broad subject area	√	√	
Full open access with APC	√	√	√
Secondary criteria			
Moderate APC			√
High prestige publisher			
Academic editors	√	√	√
Reusable graphics & data			
Altmetrics			
Commenting			√
Portable reviews			
Rapid publication	√		√

Table 2

The mega-journals studied with basic information about them.

Journal	APC USD	Publisher	Subject field	Impact factor
AIP Advances	1350	American Institute of Physics	Physics	1.6
Biology Open	1350	The Company of biologists	Biology	WoS
BMJ Open	1875	BMJ Publishing Group	Medicine	2.1
Elementa, Science of the Antropocene	1450	BioOne	Earth Sciences	
FEBS Open Bio	1200	Elsevier	Molecular sciences	WoS
G3	1950	Genetics Society of America	Genetics	2.5
IEEE Access	1750	IEEE	Electronics	
Journal of Engineering	1150	IET	Engineering	
PeerJ	400	PeerJ	Biology, medicine	WoS
PLOS ONE	1350	PLOS	Science, medicine	3.5
Royal Society Open Science	1600	Royal Society	All sciences	
SAGE Open	195	SAGE	Social Science	
Scientific Reports	1495	Nature Publishing Group	Natural sciences	5.1
Springer Plus	1085	Springer	All sciences	WoS

Table 3

Development of article volumes in mega-journals 2010-2015. The figures for 2015 are the articles published in the first quarter of the year multiplied by four.

Journal/ articles per year	2010	2011	2012	2013	2014	2015	All years
PLOS ONE	6913	13833	23441	31882	30054	22120	128243
Scientific Reports		211	800	2553	3941	7692	15197
BMJ Open		109	655	959	1037	1080	3840
Springer Plus			82	692	762	612	2148
AIP Advances		255	380	396	509	548	2088
PeerJ				232	471	636	1339
G3		65	257	250	272	176	1020
SAGE Open		44	113	225	217	360	959
Biology Open			143	162	137	160	602
FEBS Open Bio		4	52	78	120	120	374
Royal Society Open Science					50	196	246
IEEE Access				63	106	64	233
Journal of Engineering				20	102	80	202
Elementa				13	16	28	57
All journals	6913	14521	25923	37525	37794	33872	156548

Table 4

Secondary features in use in the studied mega-journals

Journal/ Features	Moderate APC	High prestige publisher	Academic editors	Reusable graphics & data	Altmetrics	Commenting	Portable reviews	Rapid publ.
AIP Advances	√	√	√	√	√	√	√	?
Biology Open	√	√	√	√	√		√	?
BMJ Open		√		√	√	√		√
Elementa	√	√	√	√	√			?
FEBS Open Bio	√	√	√	√	√			?
G3		√	√	√	√	√	√	?
IEEE Access		√	√		√	√		?
Journal of Engineering		√	√		√	√		?
PeerJ	√		√	√	√	√	√	√
PLOS ONE	√	√	√	√	√	√	√	√
Royal Society Open Science		√	√	√	√		√	?
SAGE Open	√	√		√	√	√	√	?
Scientific Reports	√	√	√	√	√		√	√
Springer Plus	√	√		√	√	√	√	√
